- `Chapter9/CornerFinite`, `BoundaryCover`, `StokesTextHypotheses`, `HemisphereBoundaryMeasure`: the class conditions derived, Theorems 9.5.15–9.5.18 with the text's hypotheses for $n \geq 2$ (§IX.36); `AllStructures`: the local formula for every structure (§IX.37).
- `Chapter9/AllStructuresDimOne`, `HalfCircleSheet`, `HalfCircleWitness`, `BoundaryMeasureDimOne`, `FaceIntegralDimOne`, `FinitePointIntegration`, `HemisphereStokesEffective`, `HemisphereStokesLUC`, `EffectiveDimOneLUC`, `StokesDimOne`, `ZeroFormValues`: $n = 1$, 0-forms, finite sets of points, the half-circle, and the local unique continuation property of the witnesses (§IX.38).
- `Chapter9/DimensionJumpRetract`, `DimensionJumpPolyfold`, `CyclicGroupoidIsotropy`: Remark 9.5.20, the M-polyfold, the groupoid and the effective isotropy (§IX.39).

Throughout, $X = (X, \mathbf{X})$ is an ep-groupoid as in Part VII, s, t its source and target, $\pi : X \to |X|$ the orbit map, X^∞ the full subcategory of smooth objects, G_x the isotropy group of x with a natural representation (Φ, Γ) on a neighbourhood $U(x)$ (§VII.4). A *submanifold* is a smooth finite-dimensional submanifold in the sense of Part I (§IV.2): the image, near each of its points, of an sc⁺-retraction. For $\Theta : X \to \mathbb{Q}$, $\mathrm{supp}(\Theta) = \{\Theta > 0\}$ and $|\mathrm{supp}(\Theta)| = \pi(\mathrm{supp}(\Theta))$. A local branching structure at x is $(U(x), (M_i)_{i\in I}, (\sigma_i)_{i\in I})$ as in Definition 9.1.2; we write $I_y = \{i \mid y \in M_i\}$ and $M_U = \bigcup_i M_i$.

IX.1 Definition 9.1.2 (2017: 9.1), and the dimension of a submanifold (Remark 9.1.1 (2017: 9.1))

Definition 9.1.2 (2017: 9.1) (V9.1) `Chapter9/Basic · EpGroupoid.IsBranchedEpSubgroupoid` `Chapter9/Basic · EpGroupoid.LocalBranchingStructure`. A branched ep⁺-subgroupoid is a functor $\Theta \geq 0$ `Chapter9/Basic · EpGroupoid.IsFunctorial` with $\mathrm{supp}(\Theta) \subseteq X_\infty$ `Chapter9/Basic · EpGroupoid.supp`, $|\mathrm{supp}(\Theta)|$ paracompact `Chapter9/Basic · EpGroupoid.orbitSupp`, and a local branching structure at every point of the support. The formalization reads the paracompactness of the induced topology as a `ParacompactSpace` instance on the subtype $|\mathrm{supp}(\Theta)|$, and "the inclusion $M_i \to U(x)$ is proper" as `IsProperMap` of the inclusion of subtypes. For a closed M_i in $U(x)$ the latter is automatic `Chapter9/Symmetric · isProperMap_inclusion_iff`. Witnesses: the zero functor `Chapter9/Basic · EpGroupoid.isBranchedEpSubgroupoid_zero` and the indicator of a smooth point of $\mathbb{R}^n$, a 0-dimensional submanifold `Chapter9/Basic · rnPolyfold_isSmoothSubmanifold_singleton` `Chapter9/Basic · EpGroupoid.localBranchingStructure_indicator` `Chapter9/Basic · EpGroupoid.isBranchedEpSubgroupoid_indicator`. The 2017 text refers in (4) to "(ii) and (iii)", the 2021 text to (2) and (3).

The dimension (V9.2). Remark 9.1.1 says that $m \mapsto \dim T_m M$ is locally constant. With $T_m M$ a set of tangent vectors, the dimension is measured in a chart: M has dimension k at a if the tangent space at the chart image of a of the sub-retract presenting M is k-dimensional `Chapter9/Propositions · MPolyfold.HasDimAt`. *Step 1, chart independence.* A germ of sc-diffeomorphisms between retracts restricts to a linear isomorphism of the tangent spaces of sub-retracts `Chapter9/Propositions · finrank_span_tangentSpace_eq`, so the value is the same for every chart and every presentation `Chapter9/Propositions · MPolyfold.finrank_tangentSpace_chart_change` `Chapter9/Propositions · MPolyfold.HasDimAt.finrank_eq`; it is unique `Chapter9/Propositions · MPolyfold.HasDimAt.unique` and exists at every point `Chapter9/Propositions · MPolyfold.IsSmoothSubmanifold.exists_hasDimAt`. *Step 2, invariance.* It is unchanged by intersecting with an open set and by sc-diffeomorphisms `Chapter9/Propositions · MPolyfold.hasDimAt_inter_isOpen_iff` `Chapter9/Propositions · MPolyfold.hasDimAt_image_iff`. *Step 3, local constancy* `Chapter9/AppendixSlices · MPolyfold.HasLocallyConstantDimAt` holds on every M-polyfold `Chapter9/GeneralLevelZero · MPolyfold.hasLocallyConstantDimAt`: in a chart the dimension is the rank of Dt for the chart sc⁺-retraction t presenting the submanifold `Chapter9/GeneralLevelZero · hasDimAt_finrank`, and this rank is locally constant along the retract `Chapter9/GeneralLevelZero · eventually_finrank_eq` (§IX.27). On $\mathbb{R}^m$ it was proved first: $T_y M$ is the range of the projection $Ds(y)$, whose rank is its trace, continuous in y and integer valued `Chapter9/AppendixSlices · MPolyfold.hasLocallyConstantDimAt_rn`. The dimensions of the sheets of one structure enter as labellings; all sheets of one structure pass through x, so a labelling is unique `Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.dim_unique`, and by local constancy every point of the support has a labelled structure `Chapter9/GeneralCorollaries · hasLabelledBranchingAt_general`.

n-dimensional Θ. The 2021 text says the sheets "can be taken" n-dimensional (2017: are n-dimensional), and this is the formal reading: some local branching structure at each point of the support has only n-dimensional sheets `Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.IsOfDim` `Chap-`

ter9/Propositions · EpGroupoid.IsNDimensional. The zero functor is n-dimensional for every n Chapter9/Propositions · EpGroupoid.isNDimensional_zero. **The footnote**, that an n-dimensional Θ is not m-dimensional for $m \neq n$, is proved for Θ with nonempty support Chapter9/LocallyEquidimensional2021 · definition_9_1_2_footnote Chapter9/LocallyEquidimensional2021 · definition_9_1_2_footnote_of_ne_zero. *Step 1.* At a point of the support two structures, one with n-dimensional and one with m-dimensional sheets, give the same tangent sum (Theorem 9.2.1, now unconditional, §IX.10), so some sheet of the first has the tangent space of some sheet of the second Chapter9/LocallyEquidimensional2021 · exists_submanifoldTangent_eq. *Step 2.* Equal tangent spaces have equal dimensions, so $m = n$ Chapter9/LocallyEquidimensional2021 · isOfDim_unique. For $\Theta = 0$ the footnote does not hold as we read it, the zero functor being n-dimensional for every n Chapter9/LocallyEquidimensional2021 · definition_9_1_2_footnote_zero. "Locally equidimensional" is formalized in both readings, which agree: at every point of the support some structure has sheets of one dimension Chapter9/LocallyEquidimensional2021 · IsLocallyEquidimensional, iff at every such point there is an n such that every structure there, restricted to a small enough neighbourhood, has only n-dimensional sheets Chapter9/LocallyEquidimensional2021 · isLocallyEquidimensional_iff, the book's "sufficiently small"; nearby points of the support then have structures of the same dimension Chapter9/LocallyEquidimensional2021 · IsLocallyEquidimensional.exists_isOpen_isNDimensionalAt (gap G.93, closed).

Submanifolds of $\mathbb{R}^n$ (V9.3). The witnesses of the chapter are built from closed submanifolds of $\mathbb{R}^n$. The image of a smooth idempotent s is one, of dimension rank $Ds(a)$ Chapter9/Propositions · rnPolyfold_isSmoothSubmanifold_range Chapter9/Propositions · rnPolyfold_hasDimAt_range. The graph of a smooth $\beta : \mathbb{R} \to \mathbb{R}$ is the image of $(s,t) \mapsto (s, \beta(s))$ Chapter9/Propositions · graphRetraction Chapter9/Propositions · rnPolyfold_isSubmanifoldOfDim_graph2. Finite weighted sums of closed submanifolds, and indicators of locally closed ones, are branched ep⁺-subgroupoids of the trivial ep-groupoid Chapter9/Propositions · EpGroupoid.isBranchedEpSubgroupoid_sum_rn Chapter9/Propositions · EpGroupoid.isNDimensional_sum_rn Chapter9/Propositions · EpGroupoid.isBranchedEpSubgroupoid_indicator_rn, whose orbit space is $\mathbb{R}^n$, so the paracompactness is free Chapter9/Propositions · EpGroupoid.paracompactSpace_orbitSupp_trivial_rn.

IX.2 Remark 9.1.3 (b) (2017: 9.2 (b)), Lemma 9.1.5 (2017: 9.1), Definitions 9.1.6 and 9.1.8 (2017: 9.2 and 9.3)

Remark 9.1.3 (b) (2017: 9.2 (b)) (V9.4) Chapter9/Propositions · EpGroupoid.remark_9_1_3_b. The text takes β_1, β_2 with prescribed signs, the graphs G_1, G_2 with weight 1, and $\Theta(p) = \#\{i \mid p \in G_i\}$ Chapter9/Propositions · EpGroupoid.thetaGraphs Chapter9/Propositions · EpGroupoid.thetaGraphs_eq, and says that the graphs of $\gamma_1 = 0$ and of some γ_2 positive off 0 describe Θ too. *Step 1.* The sign conditions are the structure `Remark913Hyp` Chapter9/Propositions · EpGroupoid.Remark913Hyp, satisfied by $\beta_1(s) = e(s)$, $\beta_2(s) = e(-s)$ with Mathlib's `expNegInvGlue` e Chapter9/Propositions · EpGroupoid.remark913Hyp_expNegInvGlue. *Step 2.* For the second structure to describe the same Θ, γ_2 must be $\beta_1 + \beta_2$ Chapter9/Propositions · EpGroupoid.Remark913Hyp.eq_add_of_thetaGraphs_eq, which is smooth and positive off 0 Chapter9/Propositions · EpGroupoid.Remark913Hyp.γ₂_pos. The two structures are Chapter9/Propositions · EpGroupoid.Remark913Hyp.structureβ and Chapter9/Propositions · EpGroupoid.Remark913Hyp.structureγ. *Step 3.* "Not unique, even close to x" is read as: no sheet of the first structure agrees with a sheet of the second on any neighbourhood of the origin, since each of β_1, β_2 differs from 0 and from $\beta_1 + \beta_2$ at points arbitrarily close to 0.

Lemma 9.1.5 (2017: 9.1) (V9.5) Chapter9/Basic · EpGroupoid.lemma_9_1_5. *$|\mathrm{supp}(\Theta)|$ is locally closed in $|X|$.* **The text's proof** takes a neighbourhood with the natural G_x-action, the properness property and a local branching structure, and shows that the image of $\bigcup_i M_i$ is closed in the image of $U(x)$. **The**

formalized proof. *Step 1.* For a functor the support is saturated, $\pi^{-1}(|\mathrm{supp}(\Theta)|) = \mathrm{supp}(\Theta)$ `Chapter9/Basic · EpGroupoid.preimage_π_orbitSupp`. *Step 2.* On $U(x)$ the support is $\bigcup_i M_i$ `Chapter9/Basic · EpGroupoid.LocalBranchingStructure.mem_supp_iff`, a finite union of sets closed in $U(x)$ `Chapter9/Symmetric · EpGroupoid.LocalBranchingStructure.isClosed_M` `Chapter9/Basic · EpGroupoid.LocalBranchingStructure.isClosed_preimage_val_supp`, so $\mathrm{supp}(\Theta)$ is locally closed in X `Chapter9/Basic · EpGroupoid.isLocallyClosed_supp`. *Step 3.* π is open (Chapter 7), and the image of the locally closed saturated set is locally closed. The properness property of the text is not used.

Definitions 9.1.6 and 9.1.8 (2017: 9.2 and 9.3) (V9.6, V9.8) are read literally `Chapter9/Basic · EpGroupoid.IsClosedBranched` `Chapter9/Basic · EpGroupoid.IsCompactBranched` `Chapter9/Basic · EpGroupoid.IsOrbifoldType` `Chapter9/Basic · EpGroupoid.IsManifoldType`; the indicator of a point is compact and of manifold type `Chapter9/Basic · EpGroupoid.isCompactBranched_indicator` `Chapter9/Basic · EpGroupoid.isManifoldType_indicator`. Proposition 9.1.9 and Remark 9.1.10 (natural manifold and orbifold structures on $|\mathrm{supp}(\Theta)|$) and Remark 9.1.4 (metrizability, the compactness criterion) are proved in §IX.26 (gaps G.94, G.95, closed).

IX.3 The restriction remark, and Lemma 9.1.7 (2017: 9.2)

The restriction (V9.7). Before Lemma 9.1.7 the text replaces M_i by $N_i = M_i \cap V(x_0)$ for $V(x_0) \subseteq U(x)$ and notes that some N_i may be empty. Definition 9.1.2 asks $x \in M_i$, which the N_i need not satisfy at x_0; the remark is formalized for an open $V \subseteq U(x)$ containing x itself, which is the case the symmetrization uses `Chapter9/Symmetric · EpGroupoid.LocalBranchingStructure.restrict`. The N_i are submanifolds `Chapter9/Symmetric · MPolyfold.IsSmoothSubmanifold.inter_isOpen`, and they are properly embedded in V because they are closed in $U(x)$.

Lemma 9.1.7 (2017: 9.2) (V9.7) `Chapter9/Symmetric · EpGroupoid.lemma_9_1_7` `Chapter9/Symmetric · EpGroupoid.lemma_9_1_7'`. *At $x \in \mathrm{supp}(\Theta)$ there is a local branching structure on the domain of a natural representation of G_x, with a G_x-action on the index set, $g * M_i = M_{g(i)}$ and $\sigma_{g(i)} = \sigma_i$; it can be found inside every open $V \ni x$.* **The text's proof** sets $J = I \times G_x$, $M_{(i,g)} = g * M_i$, $\sigma_{(i,g)} = \sigma_i/|G_x|$ and computes $\sum_{y \in g*M_i} \sigma_{(i,g)} = \frac{1}{|G_x|}\sum_g \Theta(g^{-1} * y) = \Theta(y)$ by functoriality. **The formalized proof** follows it `Chapter9/Symmetric · EpGroupoid.LocalBranchingStructure.symmetrize` `Chapter9/Symmetric · EpGroupoid.SymmetricBranchingStructure`. *Step 1.* Restrict the given structure to the domain $U \subseteq V \cap U(x)$ of a natural representation (Theorem 7.1.13, §VII.4). *Step 2.* $\Phi(g)(M_i \cap U)$ is a submanifold properly embedded in U through x, since $\Phi(g)$ is an sc-diffeomorphism of U fixing x `Chapter9/Symmetric · MPolyfold.IsSmoothSubmanifold.image_of_isScDiffeoOn`; the text uses this without saying so. *Step 3.* The weights: $\Theta(\Phi(g)(y)) = \Theta(y)$ `Chapter9/Symmetric · EpGroupoid.IsFunctorial.apply_Φ` and $y \in \Phi(g)(A) \iff \Phi(g)^{-1}(y) \in A$ `Chapter9/Symmetric · EpGroupoid.NaturalRep.mem_image_Φ_iff` turn the text's computation into a sum over G_x with $|G_x| =$ `Nat.card` of the finite group. *Step 4.* G_x acts on J by left multiplication on the second factor `Chapter9/Symmetric · EpGroupoid.mulActionProdLeft`.

IX.4 Proposition 9.1.11 (2017: 9.2): the local construction, and the uniqueness

Proposition 9.1.11 (2017: 9.2) (V9.9) `Chapter9/Propositions · EpGroupoid.Proposition_9_1_11`. *A branched ep⁺-subgroupoid determines a unique sequence $\Theta_0, \Theta_1, \ldots$ of branched ep⁺-subgroupoids with Θ_k k-dimensional and $\Theta = \sum_k \Theta_k$, locally finite.* The formal statement: for every branched Θ there is exactly one family (Θ_k)

with `IsDimDecomposition` Chapter9/Propositions · EpGroupoid.IsDimDecomposition, every Θ_k branched and k-dimensional, at each object finitely many nonzero and Θ their sum, and every such family is locally finite Chapter9/Propositions · EpGroupoid.IsLocallyFiniteFamily.

The local construction. The text splits the indices of a symmetric structure by the dimension of M_i and puts $\Theta_k(y) = \sum_{i\in I_k, y\in M_i} \sigma_i$. Formally, for a labelling dim, Θ_k Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.dimPart has the k-dimensional local branching structure $(M_i)_{\dim i=k}$ Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.dimPartStructure Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.dimPartStructure_isOfDim and $\Theta = \sum_k \Theta_k$ on $U(x)$ Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.eq_sum_dimPart; $\Theta_k = 0$ if no sheet has dimension k Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.dimPart_eq_zero, and $\Theta_n = \Theta$ for an n-dimensional structure Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.dimPart_eq_of_isOfDim. For a symmetric structure G_x preserves dimension, since $\Phi(g)$ is an sc-diffeomorphism Chapter9/Propositions · EpGroupoid.SymmetricBranchingStructure.dim_smul, so Θ_k is G_x-invariant Chapter9/Propositions · EpGroupoid.SymmetricBranchingStructure.dimPart_Φ. That the local Θ_k does not depend on the structure is Proposition 9.1.12 (§IX.5).

The uniqueness, as we read it, does not hold Chapter9/Propositions · EpGroupoid.not_proposition_9_1_11_rn. On the trivial ep-groupoid of $\mathbb{R}^2$, let L be the x-axis Chapter9/Propositions · EpGroupoid.axis2 and $\Theta = 1_L$. *Family A:* $\Theta_0 = 1_{\{0\}}$, $\Theta_1 = 1_{L\setminus\{0\}}$ Chapter9/Propositions · EpGroupoid.decompA Chapter9/Propositions · EpGroupoid.decompA_isDimDecomposition. *Family B:* $\Theta_0 = 0$, $\Theta_1 = 1_L$ Chapter9/Propositions · EpGroupoid.decompB Chapter9/Propositions · EpGroupoid.decompB_isDimDecomposition. In family A, $L\setminus\{0\}$ is a 1-dimensional submanifold properly embedded in the open set $\mathbb{R}^2\setminus\{0\}$, which is all Definition 9.1.2 asks at its points, and $1_{\{0\}}$ is 0-dimensional; both families satisfy (1) and (2). The proof of the text constructs family B.

The repaired uniqueness. Call a decomposition *local* if near every point of $\mathrm{supp}(\Theta)$ its Θ_k is the k-dimensional part of a local branching structure of Θ, which is what the text's proof produces Chapter9/DimDecompositionUnique · IsLocalDimDecomposition. Family B is local and family A is not Chapter9/DimDecompositionUnique · decompB_isLocalDimDecomposition Chapter9/DimDecompositionUnique · decompA_not_isLocalDimDecomposition. Two local decompositions are equal: near a point of the support both are dimensional parts of structures there, which agree near the point by Proposition 9.1.12, and off the support both vanish Chapter9/DimDecompositionUnique · isDimDecomposition_unique. Proposition 9.1.12 now holds on every ep-groupoid (§IX.5), so the uniqueness among local decompositions has no hypothesis Chapter9/GeneralCorollaries · proposition_9_1_11_unique.

The global decomposition (gap G.96, closed). *Step 1, the definition.* $\Theta_k(y)$ is the sum of the weights of the k-dimensional sheets of a chosen labelled structure at y, and 0 if there is none Chapter9/DimDecompositionExists · HasLabelledBranchingAt Chapter9/DimDecompositionExists · dimComponent. Every sheet passes through its base point, so this is the value at y of the local Θ_k at y. *Step 2, independence and locality.* By Proposition 9.1.12, $\Theta_k(x)$ is the same for every labelled structure at x Chapter9/DimDecompositionExists · dimComponent_eq_self, and on all of $U(x)$ it is the k-dimensional part of any labelled structure at x, restricted to y Chapter9/DimDecompositionExists · dimComponent_eq_of_mem Chapter9/DimDecompositionExists · dimPart_restrictAt. *Step 3, functoriality.* Along a morphism φ, a labelled structure at $s(\varphi)$ is transported to $t(\varphi)$, preserving dimensions Chapter9/DimDecompositionExists · isSubmanifoldOfDim_transport, and Step 2 at the target gives $\Theta_k(s(\varphi)) = \Theta_k(t(\varphi))$ Chapter9/DimDecompositionExists · isFunctorial_dimComponent; the text's symmetric structures are not needed. *Step 4, paracompactness*, which the text does not discuss: $|\mathrm{supp}(\Theta_k)|$ is closed in $|\mathrm{supp}(\Theta)|$ Chapter9/

DimDecompositionExists · isClosed_orbitSupp_dimComponent Chapter9/DimDecompositionExists · paracompactSpace_orbitSupp_dimComponent. *Step 5.* So each Θ_k is a k-dimensional branched ep⁺-subgroupoid Chapter9/DimDecompositionExists · isBranchedEpSubgroupoid_dimComponent Chapter9/DimDecompositionExists · isNDimensional_dimComponent, the family is a local decomposition Chapter9/GeneralCorollaries · isLocalDimDecomposition_dimComponent_general, and for every ep-groupoid there is exactly one local decomposition Chapter9/GeneralCorollaries · existsUnique_localDimDecomposition_general. *Step 6, local finiteness.* At the points of the support only finitely many Θ_k are nonzero nearby, those of the sheets of one structure Chapter9/GeneralCorollaries · dimComponent_locallyFinite_of_mem_general. At points of the closure of the support outside it, the formalization needs a bound on the dimensions of the submanifolds of X Chapter9/GeneralCorollaries · proposition_9_1_11_local_of_le, which holds on $\mathbb{R}^m$ Chapter9/DimDecompositionExists · rn_hasDimAt_le Chapter9/DimDecompositionExists · proposition_9_1_11_local_rn. For the line L the construction gives family B Chapter9/DimDecompositionExists · dimComponent_axis2. Row V9.9 is narrower for these two reasons: "uniquely" is read among local decompositions, and local finiteness off the support uses the bound.

IX.5 Proposition 9.1.12: the statement and its cases

Proposition 9.1.12 (V9.10) Chapter9/Propositions · EpGroupoid.Proposition_9_1_12, new in the 2021 edition. *For two local branching structures of Θ on $U(x)$ there is an open G_x-invariant $V(x) \subseteq U(x)$ on which the dimensional decompositions agree.* The formal conclusion is `DimPartsAgreeNear`: an open $V \ni x$ in both domains on which $\Theta_k = \Theta'_k$ for every k Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.DimPartsAgreeNear. "G_x-invariant, with the usual properties" is obtained by shrinking V to the domain of a natural representation Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.DimPartsAgreeNear.exists_naturalRep. *The equidimensional case* is immediate, since then $\Theta_n = \Theta$ for both Chapter9/Propositions · EpGroupoid.LocalBranchingStructure.dimPartsAgreeNear_of_isOfDim. The general case is proved in Appendix §9.6.1 (§§IX.21–IX.22): under the hypothesis `TopMultiplicity` Chapter9/Appendix · EpGroupoid.proposition_9_1_12_of_topMultiplicity, under the graph representation Chapter9/AppendixSlices · EpGroupoid.proposition_9_1_12_of_hasGraphChartAt, without hypothesis on every ep-groupoid over $\mathbb{R}^m$ Chapter9/AppendixSlices · EpGroupoid.proposition_9_1_12_rn, and now without hypothesis on every ep-groupoid Chapter9/GeneralCorollaries · proposition_9_1_12: `TopMultiplicity` holds on every M-polyfold, by the slice argument of §IX.22 run with one cone per tangent space (§IX.27) Chapter9/GeneralCorollaries · topMultiplicity. Mixed structures exist: $\Theta = 1 + \delta_0$ on $\mathbb{R}^1$ has sheets of dimensions 0 and 1 Chapter9/Appendix · exists_mixed_rn_one, and on $\mathbb{R}^2$ two labelled structures of one Θ with sheets of dimensions 1 and 0 have different sheets and agreeing dimensional parts Chapter9/AppendixSlices · EpGroupoid.Remark913Hyp.exists_mixed_rn_two.

IX.6 The category $\mathrm{Gr}(X)$, and the tangent spaces T_yM

T_yM (V9.12). Part I's Remark 4.2.2 (preprint: 4.14) defines $T_yM = Tr(y)(T_yX)$ for an sc⁺-retraction r with image M near y. Here T_yM is the set of tangent vectors at y fixed by the tangent of r Chapter9/Tangent · MPolyfold.submanifoldTangent. *Step 1.* It does not depend on the retraction Chapter9/Tangent · MPolyfold.mem_submanifoldTangent_iff Chapter9/Tangent · MPolyfold.submanifoldTangent_congr, lies in the fibre over y Chapter9/Tangent · MPolyfold.submanifoldTangent_subset_tangentFiber, is local Chapter9/Tangent · MPolyfold.submanifoldTangent_inter_isOpen, and is mapped onto $T_{f(y)}f(M)$ by an sc-diffeomorphism f Chapter9/Tangent · MPolyfold.submanifoldTangent_image. *Step 2, the chart form.* In a chart the second components of the images of T_yM form a set Chapter9/TangentSlicesBasic · MPolyfold.

chartTangent equal to the tangent space of the chart model of M Chapter9/TangentSlicesBasic · MPolyfold.chartTangent_eq, a linear subspace Chapter9/TangentSlicesBasic · MPolyfold.exists_submodule_chartTangent of dimension $\dim_y M$ Chapter9/TangentSlicesBasic · MPolyfold.finrank_chartTangent; a chart change acts on it by a continuous linear map Chapter9/TangentSlicesBasic · MPolyfold.exists_clm_tangentChartMap_snd Chapter9/TangentSlicesBasic · MPolyfold.chartTangent_chart_change, a linear isomorphism Chapter9/TangentSlicesBasic · MPolyfold.exists_linearEquiv_chartTangent. So the generators T_xM_i of $T_\Theta(x)$ are linear subspaces in every chart Chapter9/TangentSlicesBasic · EpGroupoid.LocalBranchingStructure.exists_submodule_of_mem_support, which is what the text means by "finite-dimensional linear subspaces of T_xX".

$\mathrm{Gr}(X)$ (V9.11). $\mathrm{Gr}(x)$ is the additive group of finitely supported $\mathbb{Q}$-valued functions on subsets of T_xX Chapter9/Tangent · EpGroupoid.Gr, a morphism $\varphi : x \to y$ acts by the image under its tangent $T\varphi$ (Chapter 7) Chapter9/Tangent · EpGroupoid.grPush, with $T1_x = \mathrm{id}$ Chapter9/Tangent · EpGroupoid.tangentMor_unit_of_eq and $T\varphi$ injective on the fibre Chapter9/Tangent · EpGroupoid.tangentMor_injOn; the push-forward is functorial Chapter9/Tangent · EpGroupoid.grPush_comp Chapter9/Tangent · EpGroupoid.grPush_unit. The objects (x, a) Chapter9/Tangent · EpGroupoid.GrObj form a category over the full subcategory X^∞ Chapter9/Tangent · EpGroupoid.SmoothCat with the projection π Chapter9/Tangent · EpGroupoid.grProj.

IX.7 Good points: Definitions 9.2.2 and 9.2.6 (2017: 9.4 and 9.5), Lemmas 9.2.3 and 9.2.5 (2017: 9.3 and 9.4), Remark 9.2.4 (2017: 9.4)

Definition 9.2.2 (2017: 9.4) (V9.15) Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.IsGoodPoint. $y \in M_U$ Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.MU is good if there is an open $V(y) \subseteq U(x)$ on which all sheets through y coincide. The text states this for equidimensional Θ; no proof below uses equidimensionality, so the definition and Lemmas 9.2.3 and 9.2.5 are stated for every Θ with a local branching structure.

The intrinsic form Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.isGoodPoint_iff. *For $y \in U(x)$: y is good iff $y \in \mathrm{supp}(\Theta)$ and Θ is constant on $\mathrm{supp}(\Theta)$ near y. Step 1.* Near y take V in the complement of the sheets not through y Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.nbhdAt Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.isOpen_nbhdAt; there $\Theta(z) \le \Theta(y)$ Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.le_of_mem_nbhdAt, with equality iff z lies on all sheets through y Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.eq_iff_of_mem_nbhdAt. *Step 2.* If all sheets through y coincide on V, Θ is $\Theta(y)$ on $\mathrm{supp}(\Theta) \cap V$; conversely, if Θ is constant on the support near y, every point of a sheet through y near y lies on all of them, by Step 1.

Lemma 9.2.3 (2017: 9.3) (V9.16) Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.lemma_9_2_3 follows at once, for any two structures, at possibly different points, whose domains contain y: the intrinsic form does not mention the structure. This is the text's argument, in which $Q(z) = V(y) \cap W(y)$ is presumably $Q(y)$.

Remark 9.2.4 (2017: 9.4) (V9.17). (a) Chapter9/GoodPoints · EpGroupoid.remark_9_2_4_a is Lemma 9.2.3 with the good set of Definition 9.2.6 Chapter9/GoodPoints · EpGroupoid.mem_goodSet_iff. (b) Chapter9/GoodPoints · EpGroupoid.remark_9_2_4_b: near a good y, $\Theta = \Theta(y) \cdot 1_M$ with $M = M_i \cap V(y)$ for any $i \in I_y$, properly embedded in $V(y)$ Chapter9/GoodPoints · EpGroupoid.LocalBranchingStructure.restrictAt.

Lemma 9.2.5 (2017: 9.4) (V9.18) Chapter9/GoodPoints · EpGroupoid.lemma_9_2_5. *$s(\varphi)$ is good iff $t(\varphi)$ is good.* The text transports local branching structures along morphisms. The formal proof uses the intrinsic form and the sheet of φ: on a sheet $\mathbf{W}$ of s around φ, $\widehat{\varphi} = t \circ (s|\mathbf{W})^{-1}$ is an sc-diffeomorphism between open

neighbourhoods of $s(\varphi)$ and $t(\varphi)$ with $\Theta \circ \hat{\varphi} = \Theta$ `Chapter9/GoodPoints · EpGroupoid.Sheet.apply_hat`, so "Θ constant on the support near the point" passes from one to the other `Chapter9/GoodPoints · EpGroupoid.src_mem_goodSet_of_tgt`.

Definition 9.2.6 (2017: 9.5) (V9.19) `Chapter9/GoodPoints · EpGroupoid.goodSet` `Chapter9/GoodPoints · EpGroupoid.badSet`. Both sets are saturated `Chapter9/GoodPoints · EpGroupoid.preimage_π_image_goodSet` `Chapter9/GoodPoints · EpGroupoid.preimage_π_image_badSet`, by Lemma 9.2.5. The text cites "Remark 9.2.4 (c)" here; the remark has (a) and (b), and Lemma 9.2.5 is what the descent to $|X|$ uses.

IX.8 Lemma 9.2.7 (2017: 9.5): good points are dense and accumulate on every sheet

Lemma 9.2.7 (1) (2017: 9.5 (1)) (V9.20). The openness of the good set in $\mathrm{supp}(\Theta)$ is the definition `Chapter9/GoodPoints · EpGroupoid.lemma_9_2_7_1`. **The text** derives the density from (2). **The formalized proof** needs neither (2) nor equidimensionality `Chapter9/TangentSlices · EpGroupoid.lemma_9_2_7_1_dense`. *Step 1.* Given an open $W \subseteq U(x)$ meeting the support, shrink W one sheet at a time so that $M_U \cap W$ either lies in M_j or misses it `Chapter9/TangentSlices · exists_isOpen_subset_inter_eq_empty_or_subset`: if $M_U \cap W \not\subseteq M_j$, a point of $M_U \cap W$ off the closed set M_j has a neighbourhood in W missing M_j, and the sheets already decided stay decided. *Step 2.* On the final W every sheet through a point of $M_U \cap W$ contains $M_U \cap W$, so all sheets through it agree on W and it is good. So the good set is dense `Chapter9/TangentSlices · EpGroupoid.dense_goodSet` and the bad set nowhere dense `Chapter9/TangentSlices · EpGroupoid.isNowhereDense_badSet`.

Lemma 9.2.7 (2) (2017: 9.5 (2)) (V9.21) `Chapter9/TangentSlices · EpGroupoid.lemma_9_2_7_2`. *For an n-dimensional structure at x and every i, good points of M_i converge to x.* **The text's proof** fixes i_0, sets $\Sigma_i = M_i \cap M_{i_0} \cap D_k(x)$ and either finds a point of $M_{i_0} \cap D_k(x)$ off all Σ_i or moves a point off the boundaries of those Σ_i with interior; such a point is "clearly" good. **The formalized proof** does this with Step 1 above applied inside M_{i_0}. The point found is good only if $M_{i_0} \subseteq M_i$ near it forces $M_{i_0} = M_i$ near it, which is invariance of domain for submanifolds of equal dimension. It was first the hypothesis `HasDomainInvarianceAt` `Chapter9/TangentSlices · MPolyfold.HasDomainInvarianceAt`, proved on $\mathbb{R}^m$ by the inverse function theorem `Chapter9/TangentSlices · MPolyfold.hasDomainInvarianceAt_rn` `Chapter9/TangentSlices · EpGroupoid.lemma_9_2_7_2_rn`. It now holds on every M-polyfold `Chapter9/GeneralLevelZero · hasDomainInvarianceAt`: in a chart both submanifolds are the ranges of chart sc⁺-retractions, and two such retracts with the same tangent space at the point, one inside the other, agree near it `Chapter9/GeneralLevelZero · eq_of_range_eq` (§IX.27). So Lemma 9.2.7 (2) holds for every ep-groupoid `Chapter9/GeneralCorollaries · lemma_9_2_7_2_general` (gap G.98, closed). The statement holds at every x, not only at bad points. In Remark 9.1.3 (b) the origin is bad `Chapter9/TangentSlices · EpGroupoid.Remark913Hyp.zero_mem_badSet` and is approached by good points on each graph `Chapter9/TangentSlices · EpGroupoid.Remark913Hyp.exists_seq_goodSet_structureβ`.

IX.9 Proposition 9.2.8 and Lemmas 9.2.9–9.2.11 (2017: 9.3 and 9.6–9.8): graph charts and tangent slices

The text. At a bad point x the indices with the same $T_x M_i = L$ form a class Ξ. Locally, $x = 0$ in a partial quadrant C; $L \cap C$ has interior in L (Lemma 9.2.9); the M_i, $i \in \Xi$, are graphs $a + B_i(a)$ over a cone around a unit h_0 in that interior, with an sc-complement Z of L (Lemma 9.2.10), through the inversion of a map Φ on the cone (Lemma 9.2.11). Proposition 9.2.8 then splits $\Xi = I^1 \sqcup \cdots \sqcup I^p$ with

sequences of good points $x_k^e \to x$ lying on M_i exactly for $i \in I^e$, and the proof of Theorem 9.2.1 counts $\sum_{i\in\Xi} \sigma_i = \sum_e \Theta(x_k^e)$.

What the count needs. One finite set F near x that meets each M_i, $i \in \Xi$, exactly once and misses the other sheets, so that $\sum_{i\in\Xi} \sigma_i = \sum_{y\in F} \Theta(y)$: a *tangent slice* Chapter9/Tangent · MPolyfold.HasTangentSlicesAt. The sequences of Proposition 9.2.8 are one way to produce such sets; a slice needs only one good direction $h_0 \in L$, off the finitely many other tangent spaces. So Proposition 9.2.8 is formalized in this slice form (V9.22).

The graph representation, first as a hypothesis. Lemmas 9.2.9–9.2.11 rest on sc-calculus at level 0 inside a partial quadrant (sc-complements, the mean value formula for sc⁺-retractions, an inverse function theorem on a cone). In the first version of this part their content in a chart was the hypothesis `IsGraphChartAt`, which is now proved on every M-polyfold (§IX.27; gap G.97, closed): every n-dimensional submanifold through x is, along each admissible ray th of its tangent space, met by the affine fibre through th, with secants uniformly approximated by T_xM Chapter9/TangentSlicesBasic · MPolyfold.IsGraphChartAt Chapter9/TangentSlicesBasic · MPolyfold.HasGraphChartsAt. Rays replace the cones of Lemma 9.2.10, and the admissible directions play the role of C. *From graphs to slices* Chapter9/TangentSlicesBasic · MPolyfold.hasTangentSlicesAt_of_hasGraphChartsAt: with Q a projection onto L, the slice is $\{y \mid Q(\varphi y - \varphi x) = th_0,\ \|\varphi y - \varphi x - th_0\| < \varepsilon t\}$ for small t; it meets each sheet of the class once, by the graph property, and misses the other sheets, since their tangent spaces do not contain h_0 Chapter9/TangentSlicesBasic · exists_mem_ball_forall_not_mem Chapter9/TangentSlicesBasic · eq_zero_of_proj_eq_zero. *On* $\mathbb{R}^m$ the graph representation holds at every point and in every dimension Chapter9/TangentSlicesRn · MPolyfold.isGraphChartAt_rn Chapter9/TangentSlicesRn · MPolyfold.hasGraphChartsAt_rn Chapter9/TangentSlicesRn · MPolyfold.hasTangentSlicesAt_rn: a submanifold is near x the image of a smooth retraction s, and the inverse function theorem for $Q \circ s$ restricted to L gives the graph Chapter9/TangentSlicesRn · exists_mem_graph_of_hasStrictFDerivAt Chapter9/TangentSlicesRn · MPolyfold.rn_exists_retraction.

One chart for all dimensions. For Proposition 9.6.5 and the independence of Theorem 9.2.1 without equidimensionality, the sheets of all dimensions through x must be compared in one chart: `HasGraphChartAt` asks one chart and one set of admissible directions for all of them Chapter9/AppendixSlices · MPolyfold.HasGraphChartAt Chapter9/AppendixSlices · MPolyfold.HasGraphChartAt.hasGraphChartsAt, which holds on $\mathbb{R}^m$ Chapter9/AppendixSlices · MPolyfold.hasGraphChartAt_rn. In it, every class has slices inside every neighbourhood Chapter9/AppendixSlices · MPolyfold.exists_slice_of_isGraphChartAt, which can be chosen to miss finitely many given submanifolds of smaller dimension Chapter9/AppendixSlices · MPolyfold.exists_generic_slice. For Lemma 9.3.4 good points must be found near the slice, which a ray does not provide; the ball form `HasGraphBallAt` asks the graph property over a ball of foot points Chapter9/OrientationRn · MPolyfold.HasGraphBallAt Chapter9/OrientationRn · MPolyfold.HasGraphBallAt.hasGraphChartsAt, again true on $\mathbb{R}^m$ Chapter9/OrientationRn · hasGraphBallAt_rn. On a general M-polyfold, one cone of admissible directions for all submanifolds through a boundary point is more than the slice arguments use: they need a cone for each tangent space separately, `HasClassGraphChartAt` Chapter9/GeneralLevelZero · HasClassGraphChartAt, which holds at every point Chapter9/GeneralLevelZero · hasClassGraphChartAt; the stronger `HasGraphChartAt` and `HasGraphBallAt` hold at interior points Chapter9/GeneralLevelZero · hasGraphChartAt_of_mem_interior Chapter9/GeneralLevelZero · hasGraphBallAt_of_mem_interior (§IX.27).

IX.10 Theorem 9.2.1 (2017: 9.1): the section T_Θ

Theorem 9.2.1 (2017: 9.1) (V9.13) `Chapter9/Tangent · EpGroupoid.theorem_9_2_1`. *There is a section functor* $T_\Theta : X^\infty \to \mathrm{Gr}(X)$, $\pi \circ T_\Theta = \mathrm{Id}$, *with* $T_\Theta(x) = \sum_i \sigma_i T_x M_i$ *for every local branching structure at* $x \in \mathrm{supp}(\Theta)$, *the zero sum off the support, and* $T_\Theta(\varphi) = (T_\Theta(s(\varphi)), \varphi)$. The theorem is proved in two parts. *Part 1, the section, given the independence.* Write $\sum_i \sigma_i T_x M_i$ as an element of $\mathrm{Gr}(x)$ `Chapter9/Tangent · EpGroupoid.LocalBranchingStructure.tangentSum`. If any two structures at x give the same sum `Chapter9/Tangent · EpGroupoid.HasIndependentTangentSums`, $T_\Theta(x)$ is that sum for a chosen structure, and 0 off the support `Chapter9/Tangent · EpGroupoid.tangentValue` `Chapter9/Tangent · EpGroupoid.tangentValue_eq`. For a morphism φ, a structure at $s(\varphi)$ is transported to $t(\varphi)$ by $\hat{\varphi}$ `Chapter9/Tangent · EpGroupoid.LocalBranchingStructure.transport`, which maps the sheets' tangent sets by $T\varphi$ `Chapter9/Tangent · EpGroupoid.LocalBranchingStructure.tangentSum_transport` `Chapter9/Tangent · EpGroupoid.tangentMor_eq_tangentMapOn_hat`; by the independence $T\varphi_*(T_\Theta(s(\varphi))) = T_\Theta(t(\varphi))$ `Chapter9/Tangent · EpGroupoid.grPush_tangentValue`, which makes T_Θ a functor `Chapter9/Tangent · EpGroupoid.tangentSection`.

Part 2, the independence (V9.14). *At a good point* there is no hypothesis: near it all sheets through it coincide, so the sum is $\Theta(y) \cdot T_y M$ for every structure `Chapter9/Tangent · EpGroupoid.LocalBranchingStructure.tangentSum_eq_of_isGoodPoint` `Chapter9/Tangent · EpGroupoid.hasIndependentTangentSums_of_subset_goodSet`. *Equidimensional structures* `Chapter9/Tangent · EpGroupoid.hasIndependentTangentSums_of_isOfDim`: group the sheets of both structures through x by tangent set; for each class L, a tangent slice F (§IX.9) meeting each sheet of either structure with tangent space L once gives $\sum_{T_x M_i = L} \sigma_i = \sum_{y \in F} \Theta(y) = \sum_{T_x M'_j = L} \sigma'_j$. With sheets of one dimension a slice for one structure is one for the other. *In general* the text reduces to the equidimensional case through the dimensional decomposition, and so does the formalization: if the dimensional parts of two structures agree near x (Proposition 9.1.12), their tangent sums agree dimension by dimension `Chapter9/Tangent · EpGroupoid.LocalBranchingStructure.tangentSum_eq_sum_dimPartStructure` `Chapter9/Tangent · EpGroupoid.LocalBranchingStructure.tangentSum_eq_of_dimPartsAgreeNear` `Chapter9/Tangent · EpGroupoid.hasIndependentTangentSums_of_dimPartsAgreeNear`. With one graph chart for all dimensions and the local constancy of the dimension, which supplies the labellings, the independence follows `Chapter9/AppendixSlices · EpGroupoid.hasIndependentTangentSums_of_hasGraphChartAt_of_hasLocallyConstantDimAt`; restricting a structure to a neighbourhood where the dimensions are constant is `Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.exists_restrict_labelled`. On every ep-groupoid over $\mathbb{R}^m$ both hypotheses hold, so T_Θ exists for every branched Θ `Chapter9/AppendixSlices · EpGroupoid.hasIndependentTangentSums_rn`. Now Proposition 9.1.12 holds on every ep-groupoid and labelled structures exist at every point (§IX.27), so the independence, and with it Theorem 9.2.1, holds for every branched ep⁺-subgroupoid of every ep-groupoid `Chapter9/GeneralCorollaries · hasIndependentTangentSums`; the tangent slices of the equidimensional case exist at every point too `Chapter9/GeneralCorollaries · hasTangentSlicesAt`. In Remark 9.1.3 (b) the two structures have the same tangent sum at the bad origin `Chapter9/TangentSlicesRn · EpGroupoid.Remark913Hyp.tangentSum_structureβ_eq_structureγ`. The text writes "it suffices to prove the proposition" (p. 410) for the theorem and closes with "This completes the proof of Theorem 9.2.8" (p. 418), presumably Theorem 9.2.1; in $\sum_{i \in I \mid y \in M_j} \sigma_i T_y M_i$ (p. 418) the index is presumably i.

IX.11 Definition 9.2.12 (2017: 9.6): the tangent $T\Theta$

Definition 9.2.12 (2017: 9.6) (V9.23) `Chapter9/Tangent · EpGroupoid.tangentTheta`. $T\Theta(h) = 0$ over the complement of the support and $T\Theta(h) = \sum_{h \in TM_i} \sigma_i$ over $U(x)$, with $h \in TM_i$ read as $h \in T_{p(h)} M_i$ `Chapter9/Tangent · EpGroupoid.tangentSubmanifold`. The formal definition evaluates $T_\Theta(p(h))$ at the tangent

sets containing h Chapter9/Tangent · EpGroupoid.grEval, so it does not depend on a structure by construction; that it agrees with the text's local formula for every structure Chapter9/Tangent · EpGroupoid.tangentTheta_eq is the text's "the local definitions fit together", and comes from the independence through the identity $\sum_{h\in T_yM_i}\sigma_i=\sum_{h\in T_yM'_j}\sigma'_j$ Chapter9/Tangent · EpGroupoid.sum_tangent_eq_sum_tangent. $T\Theta\geq 0$ Chapter9/Tangent · EpGroupoid.tangentTheta_nonneg and it is a functor on the tangent ep-groupoid of Chapter 8 Chapter9/Tangent · EpGroupoid.isFunctorial_tangentTheta.

Is $T\Theta$ a branched ep⁺-subgroupoid? The text says so without discussion. It needs that the TM_i are smooth submanifolds of TX of smooth points, closed in $TU(x)$, and that $|\mathrm{supp}(T\Theta)|$ is paracompact; these are the fields of `TangentBranchingHyp` Chapter9/Tangent · EpGroupoid.TangentBranchingHyp, under which the theorem holds Chapter9/Tangent · EpGroupoid.isBranchedEpSubgroupoid_tangentTheta Chapter9/Tangent · EpGroupoid.tangentBranchingStructure. *Closedness* is proved Chapter9/TangentSlices · EpGroupoid.isClosed_tangentSubmanifold. *Paracompactness* follows from that of $|X|$ Chapter9/TangentSlices · EpGroupoid.paracompactSpace_orbitSupp_tangentTheta. So only the smoothness of the TM_i remains Chapter9/TangentSlices · EpGroupoid.tangentBranchingHyp_of_isSmoothSubmanifold Chapter9/TangentSlices · EpGroupoid.isBranchedEpSubgroupoid_tangentTheta_of_isSmoothSubmanifold. TM_i is a sub-M-polyfold of TX, the image of the retraction Ts Chapter9/AppendixSlices · MPolyfold.IsSmoothSubmanifold.isSubMPolyfold_tangent Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.isSubMPolyfold_tangentSubmanifold. *That Ts is an sc⁺-retraction of TX* (gap G.99, closed): for the sc⁺-retraction s presenting a smooth finite-dimensional submanifold, $g=1^1_0\circ s$ is sc-smooth into X^1 and $Ts=T\iota\circ Tg$ for the inclusion $\iota:X^1\to X$. The tangent of ι is the natural inclusion $T(X^1)\to TX$ of Proposition 2.3.17, in a chart the tangent of the sc-operator $E^1\to E$, which is itself Chapter9/TangentSubmanifoldSmooth · retractTangentMap_shiftIncl Chapter9/TangentSubmanifoldSmooth · tangentLower_tangentMapOn_one. Hence Ts maps into $(TX)_1$ Chapter9/TangentSubmanifoldSmooth · tmap_mem_levelSet, and $1^1_0\circ Ts$ is Tg followed by the sc-diffeomorphism $T(X^1)\cong(TX)^1$, so Ts is an sc⁺-retraction of TX Chapter9/TangentSubmanifoldSmooth · isScPlusRetractionOn_tmap. So TA is a smooth submanifold of TX Chapter9/TangentSubmanifoldSmooth · IsSmoothSubmanifold.isSmoothSubmanifold_tangent, the field holds for every local branching structure Chapter9/TangentSubmanifoldSmooth · LocalBranchingStructure.isSmoothSubmanifold_tangentSubmanifold, and for $|X|$ paracompact $T\Theta$ is a branched ep⁺-subgroupoid of TX on every ep-groupoid Chapter9/TangentSubmanifoldSmooth · tangentBranchingHyp Chapter9/TangentSubmanifoldSmooth · isBranchedEpSubgroupoid_tangentTheta_general. On $\mathbb{R}^m$ this was proved first with the field as the only hypothesis Chapter9/AppendixSlices · EpGroupoid.isBranchedEpSubgroupoid_tangentTheta_rn; the tangent of a line in $\mathbb{R}^2$ is a sub-M-polyfold of $T\mathbb{R}^2$ Chapter9/AppendixSlices · rnPolyfold_isSubMPolyfold_tangent_graph2. The full hypothesis has the zero functor as witness Chapter9/Tangent · EpGroupoid.tangentBranchingHyp_zero Chapter9/Tangent · EpGroupoid.isBranchedEpSubgroupoid_tangentTheta_zero. The text's introduction (p. 408) calls $T\Theta$ a "branched ep-subgroupoid", Definition 9.2.12 an ep⁺-subgroupoid.

IX.12 Lemma 9.2.13 (2017: 9.9) and Remark 9.2.14 (2017: 9.5): the position of M relative to ∂X

Reduced tangent position in a chart (V9.24). T^R_xX is not a subspace of a vector space in the project; in a chart φ with $\varphi(x)=z$ in a partial quadrant, "$T_xM\subseteq T^R_xX$" is the inclusion of the chart image of T_xM in the reduced tangent space E_z Chapter9/BoundaryPosition · IsReducedTangentAt Chapter9/BoundaryPosition · isReducedTangentAt_iff_subset_reduced, equivalently in the partial quadrant or the partial cone at z Chapter9/BoundaryPosition · isReducedTangentAt_iff_subset_partialQuadrant Chap-

ter9/BoundaryPosition · isReducedTangentAt_iff_subset_partialCone. It does not depend on the chart Chapter9/BoundaryPosition · MPolyfold.isReducedTangentAt_chart_change Chapter9/BoundaryPosition · MPolyfold.isTangentReducedAt_iff_forall, and defines `IsTangentReducedAt` Chapter9/BoundaryPosition · MPolyfold.IsTangentReducedAt. $d_M(x)$ is the degeneracy index of the induced M-polyfold structure Chapter9/BoundaryPosition · MPolyfold.subDegIndex, at most $d_X(x)$ Chapter9/BoundaryPosition · MPolyfold.subDegIndex_le.

Lemma 9.2.13 (2017: 9.9). *For $x \in M$: (1) $x \in \partial X$ and $d_M(x) = 0$ iff (2) $T_xM \subseteq T^R_xX$.* **As printed (2) □ (1) does not hold at interior points**: for a point p of $\mathbb{R}^n$, $\{p\}$ is in reduced tangent position at p and $p \notin \partial\mathbb{R}^n$ Chapter9/BoundaryPosition · MPolyfold.not_lemma_9_2_13_two_one. The lemma is about $x \in M \cap \partial X$, where the text uses it, and is formalized there. *(1)* □ *(2)* Chapter9/BoundaryPosition · MPolyfold.lemma_9_2_13 Chapter9/BoundaryPosition · MPolyfold.lemma_9_2_13_chart: if $d_M(x) = 0$, Part I's Theorem 2.5.? (preprint: 2.31) gives a chart of M without boundary near x, whose tangent space lies in the reduced tangent space of X; the boundary hypothesis is not used, and the implication holds off ∂X too Chapter9/BoundaryPosition · MPolyfold.lemma_9_2_13_of_not_mem_boundary. *(2)* □ *(1)* Chapter9/BoundaryPositionConverse · MPolyfold.lemma_9_2_13_two_one. **The text's proof** builds a complement Y and a map F and asserts that the image is M near 0. **The formalized proof.** *Step 1.* In a chart, M is the image of an sc⁺-retraction s near z, with $T_zM \subseteq E_z$. *Step 2,* "the image is M near 0", which the text does not spell out: the projection p onto T_zM along a complement is injective on M near z, by a level-1 contraction with the mean value inequality Chapter9/BoundaryPositionConverse · ScRetraction.IsScPlus.exists_injOn_proj. *Step 3.* By Mathlib's inverse function theorem for $p \circ s$ on T_zM, $\chi = p(\cdot - z)$ is a chart of $M \cap G$ onto an open subset of $T_zM \subseteq E_z$, with inverse $s \circ (z + \cdot) \circ \Psi^{-1}$, a model without boundary Chapter9/BoundaryPositionConverse · ScRetraction.IsScPlus.exists_flat. *Step 4.* So $d_M(x) = 0$ Chapter9/BoundaryPositionConverse · MPolyfold.subDegIndex_eq_zero_of_isTangentReducedAt Chapter9/BoundaryPositionConverse · MPolyfold.degIndex_eq_zero_of_isReducedTangentAt. The complement Y and the map F are not needed. Together: the equivalence at $x \in \partial X$ Chapter9/BoundaryPositionConverse · MPolyfold.lemma_9_2_13_iff, and at every $x \in M$: $d_M(x) = 0 \iff T_xM \subseteq T^R_xX$ Chapter9/BoundaryPositionConverse · MPolyfold.subDegIndex_eq_zero_iff. The witness is a point of $\mathbb{R}^n$; a witness at a boundary point needs a submanifold API for quadrants, not yet available.

Remark 9.2.14 (2017: 9.5) (V9.25). ∂M is the boundary of the induced M-polyfold Chapter9/BoundaryPosition · MPolyfold.mem_boundary_subPolyfold_iff. *$x \in \partial M$ iff $x \in \partial X$ and $T_xM \not\subseteq T^R_xX$* Chapter9/BoundaryPositionConverse · MPolyfold.remark_9_2_14_iff: □ with $d_M(x) \geq 1$ from Lemma 9.2.13 Chapter9/BoundaryPosition · MPolyfold.remark_9_2_14; □ since $\partial M \subseteq \partial X$ Chapter9/BoundaryPosition · MPolyfold.remark_9_2_14_mem_boundary and a point of M in reduced position has $d_M = 0$ Chapter9/BoundaryPositionConverse · MPolyfold.remark_9_2_14_not_isTangentReducedAt Chapter9/BoundaryPositionConverse · MPolyfold.remark_9_2_14_not_mem_boundary_iff.

IX.13 Proposition 9.2.15 (2017: 9.4), Definition 9.2.16 (2017: 9.7) and Remark 9.2.17 (2017: 9.6): the boundary $\partial\Theta$

The boundary of a sheet. $y \in \partial M$ is characterized through T_yM (Remark 9.2.14), so the set of y with $y \in \partial M_i$ Chapter9/Boundary · MPolyfold.submanifoldBoundary Chapter9/Boundary · MPolyfold.mem_submanifoldBoundary_iff is read off the tangent sets: $y \in \partial M$ iff $y \in \partial X$ and T_yM is not in reduced position Chapter9/Boundary · MPolyfold.IsReducedTangentSet Chapter9/Boundary · MPolyfold.isReducedTangentSet_iff. It is local and invariant under sc-diffeomorphisms Chapter9/Boundary · MPolyfold.mem_submanifoldBoundary_inter_isOpen_iff Chapter9/Boundary · MPolyfold.mem_submanifoldBoundary_image_iff.

Proposition 9.2.15 (2017: 9.4) (V9.26). *(1)* The boundary weight $\sum_{y\in\partial M_i}\sigma_i$ is the part of $T_\Theta(y)$ on tangent sets not in reduced position `Chapter9/Boundary · EpGroupoid.boundaryPart` `Chapter9/Boundary · EpGroupoid.filter_tangentValue_eq`; so, under the independence of Theorem 9.2.1, it is the same for any two structures whose domains contain y `Chapter9/Boundary · EpGroupoid.proposition_9_2_15_1`. *(2)* If $d_X(y)=0$, no tangent set is out of reduced position, so the weight and the formal sum vanish for every structure, with no independence `Chapter9/Boundary · EpGroupoid.proposition_9_2_15_2`. *(3)* $\partial\Theta$, 0 off ∂X and the boundary part of T_Θ on it `Chapter9/Boundary · EpGroupoid.boundaryTheta`, is a functor `Chapter9/Boundary · EpGroupoid.isFunctorial_boundaryTheta`, nonnegative, supported in ∂X and given by the local formula on every structure `Chapter9/Boundary · EpGroupoid.boundaryTheta_eq` `Chapter9/Boundary · EpGroupoid.proposition_9_2_15_3`. (1) and (2) need neither $x\in\operatorname{supp}(\Theta)\cap\partial X$ nor that Θ be branched.

Definition 9.2.16 (2017: 9.7) (V9.27). *$\partial\Theta$ is uniquely characterized by (1) $\operatorname{supp}(\partial\Theta)\subseteq\partial X$ and (2) the local formula at points of $\operatorname{supp}(\partial\Theta)$* `Chapter9/Boundary · EpGroupoid.IsBoundaryCharacterized`. $\partial\Theta$ has (1) and (2) `Chapter9/Boundary · EpGroupoid.isBoundaryCharacterized_boundaryTheta`. **The uniqueness, as we read it, does not hold**: (2) is asked only on $\operatorname{supp}(F)$, so $F=0$ has (1) and (2) for every Θ `Chapter9/Boundary · EpGroupoid.isBoundaryCharacterized_zero`, and for $\Theta=1$ on $[0,\infty)$, where $\partial\Theta(0)=1$ `Chapter9/Boundary · boundaryTheta_halfLine_one`, both 0 and $\partial\Theta$ do `Chapter9/Boundary · not_unique_isBoundaryCharacterized_halfLine`. With (2) asked at the points of $\operatorname{supp}(\Theta)$ and $F=0$ off $\operatorname{supp}(\Theta)$, $F=\partial\Theta$ `Chapter9/Boundary · EpGroupoid.eq_boundaryTheta`. **A reading with the printed (2)** `Chapter9/BoundaryCharacterization · definition_9_2_16_existsUnique`: among the $F\geq 0$ vanishing off $\operatorname{supp}(\Theta)$ with (1) and (2), there is exactly one whose support contains the supports of all the others, and it is $\partial\Theta$. *Step 1.* Such an F agrees with $\partial\Theta$ on its own support, by (2) and the local formula for $\partial\Theta$ `Chapter9/BoundaryCharacterization · IsBoundaryCharacterized.eq_boundaryTheta_on`, so its support lies in $\operatorname{supp}(\partial\Theta)$ `Chapter9/BoundaryCharacterization · IsBoundaryCharacterized.supp_subset`. *Step 2.* Hence $F=\partial\Theta$ iff its support contains $\operatorname{supp}(\partial\Theta)$ `Chapter9/BoundaryCharacterization · IsBoundaryCharacterized.eq_boundaryTheta_iff`, and $\partial\Theta$ itself has (1) and (2). Row V9.27 is narrower for this reason. Before the definition the text writes "In view of Proposition 9.2.13" (2017: "Proposition 9.9", the number of Lemma 9.2.13 there), presumably Proposition 9.2.15, and in it "branched ep⁺-groupoid".

Remark 9.2.17 (2017: 9.6) (V9.28). $\partial\Theta\leq\Theta$ `Chapter9/Boundary · EpGroupoid.boundaryTheta_le`, and $\partial\Theta$ is not Θ restricted to ∂X: for the indicator of the corner 0 of $[0,\infty)$, $\Theta(0)=1$ and $\partial\Theta(0)=0$ `Chapter9/Boundary · boundaryTheta_halfLineCorner`, while for $\Theta=1$ on $[0,\infty)$, whose sheet is all of $[0,\infty)$ `Chapter9/Boundary · MPolyfold.HasCornerStructure.isSmoothSubmanifold_univ` `Chapter9/Boundary · EpGroupoid.isBranchedEpSubgroupoid_one`, $\partial\Theta(0)=1$ `Chapter9/Boundary · EpGroupoid.boundaryTheta_one`. For the indicator of an interior point $\partial\Theta=0$ `Chapter9/Boundary · EpGroupoid.boundaryTheta_indicator_of_mem`. The witnesses satisfy the independence `Chapter9/Boundary · EpGroupoid.hasIndependentTangentSums_indicator_of_mem`. The remark's "In Section 9.5, Definition 9.3.6" refers to §9.3.

IX.14 Orientations: $\widehat{\mathrm{Gr}}(X)$, Definition 9.3.2 (2017: 9.8) and Remark 9.3.3 (2017: 9.8)

Oriented tangent sets (V9.29). An orientation of a finite-dimensional vector space is a class of bases; for a tangent set it is a set of frames, lists of vectors of the set, whose chart images `Chapter9/OrientationTangent · MPolyfold.chartVec` `Chapter9/OrientationTangent · MPolyfold.chartVec_injOn` are the positive bases of an orientation of the chart image `Chapter9/OrientationTangent · MPolyfold.OrTangent` `Chapter9/OrientationTangent · MPolyfold.chartFrames` `Chapter9/OrientationTangent · MPolyfold.IsChartOrientation` `Chapter9/OrientationTangent · MPolyfold.IsOrientedAt`. A chart change acts linearly

Chapter9/OrientationTangent · MPolyfold.exists_clm_chartVec, so this does not depend on the chart Chapter9/OrientationTangent · MPolyfold.IsOrientedAt.isChartOrientation Chapter9/OrientationTangent · MPolyfold.isOrientedAt_iff_forall; every tangent set with linear chart image has exactly two orientations Chapter9/OrientationTangent · MPolyfold.exists_two_orientations, and sc-diffeomorphisms and morphisms push them forward Chapter9/OrientationTangent · MPolyfold.OrTangent.push Chapter9/OrientationTangent · MPolyfold.IsOrientedAt.push_tangentMapOn Chapter9/OrientationTangent · EpGroupoid.isOrientedAt_push_tangentMor. $\widehat{\mathrm{Gr}}(x)$ is generated by oriented tangent sets Chapter9/OrientationTangent · EpGroupoid.GrHat Chapter9/OrientationTangent · EpGroupoid.grHatPush Chapter9/OrientationTangent · EpGroupoid.GrHatObj Chapter9/OrientationTangent · EpGroupoid.grHatProj, and forgetting the orientation is a functor over X^∞ Chapter9/OrientationTangent · EpGroupoid.grForget Chapter9/OrientationTangent · EpGroupoid.grForgetFunctor Chapter9/OrientationTangent · EpGroupoid.grForgetFunctor_comp_grProj, adding the two orientations of a set to the set Chapter9/OrientationTangent · EpGroupoid.grForget_single_add_single. Remark 9.3.1 (2017: 9.7), on an earlier notion of orientation, has no formal content.

Definition 9.3.2 (2017: 9.8) (V9.30) Chapter9/OrientationBasic · EpGroupoid.IsOrientation. An orientation of a submanifold is a continuous choice of orientations of its tangent sets Chapter9/OrientationBasic · MPolyfold.SubmanifoldOrientation, continuity being local constancy of the chart frames; an oriented local branching structure carries one per sheet Chapter9/OrientationBasic · EpGroupoid.OrientedBranchingStructure, with oriented sum $\sum_{y\in M_i}\sigma_i T_y(M_i,o_i)$ Chapter9/OrientationBasic · EpGroupoid.OrientedBranchingStructure.orientedSum forgetting to the tangent sum Chapter9/OrientationBasic · EpGroupoid.OrientedBranchingStructure.grForget_orientedSum. An orientation of Θ assigns to each smooth object an element of $\widehat{\mathrm{Gr}}$, naturally in morphisms, forgetting to T_Θ, and locally an oriented sum; the "lifts T_Θ" clause uses T_Θ, hence the independence of Theorem 9.2.1 Chapter9/OrientationBasic · EpGroupoid.IsOrientation.mk', which on $\mathbb{R}^m$ is free Chapter9/OrientationRn · EpGroupoid.isOrientation_sum_trivial_rn. It defines a section functor Chapter9/OrientationBasic · EpGroupoid.orientedSection Chapter9/OrientationBasic · EpGroupoid.orientedSection_comp_grHatProj Chapter9/OrientationBasic · EpGroupoid.orientedSection_comp_grForgetFunctor_obj. Witnesses: $\Theta = 0$ Chapter9/OrientationBasic · EpGroupoid.isOrientation_zero, and finite weighted sums of oriented closed submanifolds of $\mathbb{R}^n$ Chapter9/OrientationBasic · EpGroupoid.isOrientation_sum_rn.

Remark 9.3.3 (2017: 9.8) (V9.31) Chapter9/OrientationBasic · EpGroupoid.remark_9_3_3. For the indicator of a point p, $T_q = q\cdot(\{p\},+) + (1-q)\cdot(\{p\},-)$, $q\in(0,1)\cap\mathbb{Q}$, are pairwise distinct orientations: a 0-dimensional tangent set has two orientations, and any split of the weight 1 between them is an orientation.

IX.15 Lemma 9.3.4 (2017: 9.10) and Example 9.3.5 (2017: 9.1)

Lemma 9.3.4 (2017: 9.10) (V9.32). *Two orientations of Θ that agree at good points are the same.* **Without equidimensionality, as we read it, the lemma does not hold** Chapter9/OrientationRn · lemma_9_3_4_mixed_dim_rn Chapter9/OrientationUniqueness · lemma_9_3_4_mixed_dim: on $\mathbb{R}^2$ let $\Theta = 1_{\mathbb{R}\times 0} + 1_{(0,0)}$ Chapter9/OrientationUniqueness · mixedTheta Chapter9/OrientationUniqueness · mixedTheta_isBranched. The origin is bad Chapter9/OrientationUniqueness · zero_not_mem_goodSet_mixed, the good points are the other points of the line, and two orientations that orient the line the same way and the point $\{0\}$ oppositely agree at all good points and differ at the origin. The lemma is formalized for n-dimensional Θ Chapter9/OrientationUniqueness · EpGroupoid.IsOrientationOfDim.

The text's proof takes, at a bad x, the sequences of good points of Proposition 9.2.8 for the first structure and compares the orientations of the two structures along them. As we read it, this needs that the same

sequences serve the second structure, which the text does not show, and that frames of different sheets can be compared along a sequence. **The formalized proof** Chapter9/OrientationUniqueness · EpGroupoid.lemma_9_3_4. *Step 1.* Its hypothesis `HasOrientedGoodPointsAt` Chapter9/OrientationUniqueness · MPolyfold.HasOrientedGoodPointsAt asks, for each class of sheets of both structures with one tangent set at x, good points near x on every sheet of the class, on which the orientations of the sheets can be compared; this is Proposition 9.2.8 applied to both families together. Under it, the oriented sums at x agree class by class, which is the lemma. *Step 2,* from the ball graph representation (§IX.9) Chapter9/OrientationRn · MPolyfold.hasOrientedGoodPointsAt_of_hasGraphBallAt: over a ball of foot points in the class tangent space each sheet of the class is a graph, the good points are dense in it (Lemma 9.2.7 (1)), and the relative orientations of the sheets are locally constant. *Step 3,* local constancy: the relative orientation of two frame fields is the sign of a determinant Chapter9/OrientationRn · frameDet Chapter9/OrientationRn · orientation_eq_iff_frameDet Chapter9/OrientationRn · MPolyfold.frames_eq_iff_frameDet, continuous if the chart frames are continuous on level 1 Chapter9/OrientationRn · MPolyfold.continuousOn_chartVec_of_continuousOn Chapter9/OrientationRn · MPolyfold.SubmanifoldOrientation.exists_isOpen_tangent_eq_iff. This continuity was first the hypothesis `HasContinuousLevelOneOn` Chapter9/OrientationRn · MPolyfold.HasContinuousLevelOneOn, true on $\mathbb{R}^m$ Chapter9/OrientationRn · hasContinuousLevelOneOn_rn, and Chapter9/OrientationRn · EpGroupoid.lemma_9_3_4_of_hasGraphBallAt holds under the two hypotheses, on every ep-groupoid over $\mathbb{R}^m$ without them Chapter9/OrientationRn · EpGroupoid.lemma_9_3_4_rn Chapter9/OrientationRn · hasOrientedGoodPointsAt_rn; witness in dimension 0: Chapter9/OrientationUniqueness · hasOrientedGoodPointsAt_rn_zero. *Step 4, no hypothesis* (gap G.100, closed). The level-1 continuity holds along every smooth finite-dimensional submanifold of every M-polyfold Chapter9/GeneralLevelZero · hasContinuousLevelOneOn: on the submanifold the level-1 lift of the chart is $1^1_0 \circ t$ composed with the chart, for the chart sc$^+$-retraction t Chapter9/GeneralLevelZero · levelLift_eq_plusLift, continuous since t is sc$^+$. The ball graph representation holds at interior points, which gave the lemma for Θ supported where $d_X = 0$ Chapter9/GeneralCorollaries · lemma_9_3_4_of_hasGraphBallAt' Chapter9/GeneralCorollaries · lemma_9_3_4_of_degIndex_eq_zero. At boundary points a ball of foot points is not available, but it is not needed: the good direction h_0 off the other tangent spaces is chosen near an admissible direction h_1, so that every h near h_0 is admissible with one radius and one factor Chapter9/GeneralBoundaryPoints · exists_small_cone, and the tangent sheets are graphs over a small ball $\{u \in T \mid \|u - th_0\| < \tau t\}$ for t below a uniform bound Chapter9/GeneralBoundaryPoints · exists_graph_unif_chart. So the good-point input holds at every point Chapter9/GeneralBoundaryPoints · hasOrientedGoodPointsAt, and Lemma 9.3.4 holds for every n-dimensional Θ of every ep-groupoid Chapter9/GeneralBoundaryPoints · lemma_9_3_4_general, every orientation of an n-dimensional Θ being n-dimensional Chapter9/OrientationAnyDim · IsOrientation.isOrientationOfDim Chapter9/OrientationAnyDim · lemma_9_3_4_of_isNDimensional. Row V9.32 stays narrower only because of the mixed-dimensional counterexample above.

Example 9.3.5 (2017: 9.1) (V9.33) Chapter9/OrientationExample · example_9_3_5 Chapter9/OrientationRn · example_9_3_5_rn. Take $\beta^{++}(s) = e(s) + e(-s)$ with $e =$ `expNegInvGlue`, $\beta^{--} = -\beta^{++}$, β^{+-} equal to β^{++} for $s \le 0$ and to β^{--} for $s > 0$, and β^{-+} the other way Chapter9/OrientationExample · betaPP Chapter9/OrientationExample · betaMM Chapter9/OrientationExample · betaPM Chapter9/OrientationExample · betaMP. The two pairs of graphs cover each point equally often Chapter9/OrientationExample · example_9_3_5_count, which defines Θ Chapter9/OrientationExample · example935Theta Chapter9/OrientationExample · example935Theta_isBranched. Orienting the graphs by $\pm(1, \beta')$ Chapter9/OrientationExample · graphOrientation Chapter9/OrientationExample · chartVec_image_graph2 gives $\hat{T}^1$ from G^{++}, G^{--} and $\hat{T}^2$ from G^{+-}, G^{-+} Chapter9/OrientationExample · exampleT1 Chapter9/OrientationExample · exampleT2. Verified as stated: they coincide at the origin Chapter9/OrientationExample · example_9_3_5_eq_origin, differ at $(s, \beta^{++}(s))$ for $s > 0$ Chapter9/

OrientationExample · example_9_3_5_ne_of_pos, and no signs for the second structure reproduce $\hat{T}^1$ near the origin Chapter9/OrientationExample · example_9_3_5_cannot_coincide. **Two claims do not hold as we read them.** "Otherwise different": they also coincide wherever $x < 0$, where $G^{+-} = G^{++}$ and $G^{-+} = G^{--}$ with the same orientations Chapter9/OrientationExample · example_9_3_5_eq_of_neg. "Four possibilities to orient": the four sign choices for the first structure give four different orientations Chapter9/OrientationExample · orientedLift1_injective, and $\hat{T}^2$ is none of them Chapter9/OrientationExample · exampleT2_ne_orientedLift1. Counting both structures, the sign choices give exactly six orientations, the two structures sharing the two constant choices Chapter9/OrientationExampleSigns · orientedLift1_eq_orientedLift2_iff Chapter9/OrientationExampleSigns · orientedLift2_injective Chapter9/OrientationExampleSigns · ncard_signOrientations Chapter9/OrientationExampleSigns · example_9_3_5_six, and with fractional weights there are infinitely many, as in Remark 9.3.3. So "four possibilities" holds for each structure and, for Θ, does not hold as we read it; the full classification is §IX.29 (gap G.101, closed). The good points distinguish $\hat{T}^1$ from $\hat{T}^2$, in line with Lemma 9.3.4 Chapter9/OrientationRn · exists_goodSet_exampleT1_ne_exampleT2.

IX.16 Definition 9.3.6 (2017: 9.10), Lemma 9.3.7, and the boundary orientation ((9.11), Definition 9.3.8, Proposition 9.3.9, Definition 9.3.10)

Definition 9.3.6 (2017: 9.10) (V9.34) Chapter9/BoundaryPosition · EpGroupoid.TameBranchingStructure Chapter9/BoundaryPosition · EpGroupoid.IsTameBranched. A tame structure has a natural representation on its domain, the properness property, and sheets with tame induced structures in the sense of Part I's Definition 2.5.18. Witnesses: $\Theta = 0$ Chapter9/BoundaryPosition · EpGroupoid.isTameBranched_zero and a point of $\mathbb{R}^n$ Chapter9/BoundaryPosition · EpGroupoid.isTameBranched_indicator Chapter9/BoundaryPosition · MPolyfold.hasTameInducedStructure_of_degIndex_eq_zero. "In particular every M_i has an equivalent structure of a manifold with boundary with corners" (gap G.102, closed): for a tame structure with n-dimensional sheets, each M_i with the subspace topology is a Mathlib manifold with corners modelled on $[0,\infty)^n$ Chapter9/MathlibManifoldBridge · TameBranchingStructure.hasCornerStructureOfDim Chapter9/MathlibManifoldBridge · TameBranchingStructure.isManifold. *Step 1.* A tame induced structure gives corner coordinates near each point, charts onto relatively open subsets of partial quadrants of $\mathbb{R}^n$ with smooth transitions Chapter9/MathlibManifoldBridge · CornerCoords Chapter9/MathlibManifoldBridge · IsSubmanifoldOfDim.hasCornerStructureOfDim_of_hasTameInducedStructure. *Step 2.* A Mathlib manifold has one model, so each partial quadrant is moved into the full quadrant by a linear isomorphism Chapter9/MathlibManifoldBridge · exists_cle_partialQuadrant, which gives a charted space Chapter9/MathlibManifoldBridge · cornerChartedSpace with smooth transitions Chapter9/MathlibManifoldBridge · isManifold_cornerChartedSpace. The same bridge serves Part I's solution sets.

Lemma 9.3.7 (V9.35) Chapter9/BoundaryPosition · MPolyfold.lemma_9_3_7, new in the 2021 edition. *For tame Y and submanifolds M_1, M_2 of one dimension with tame induced structures, $T_yM_1 = T_yM_2$ implies $d_{M_1}(y) = d_{M_2}(y)$.* **The text's proof** describes T_yM in a tame chart of M by the cone C_yM and shows that $T_0O \cap C$ is the reduced tangent space. **The formalized proof.** For a submanifold with tame induced structure, $d_M(y)$ is the codimension of the reduced part of the chart image of T_yM, which depends only on that linear space and on the partial quadrant of the chart of Y Chapter9/BoundaryPosition · MPolyfold.subDegIndex_eq_quotDim_of_hasTameInducedStructure (Remark 2.5.9 in every chart). So equal tangent spaces give equal indices Chapter9/BoundaryPosition · MPolyfold.subDegIndex_eq_of_tangentSpace_eq Chapter9/OrientationBoundary · MPolyfold.subDegIndex_eq_of_submanifoldTangent_eq, with neither "Y tame" nor "of the same dimension". The text's "$T_0O \cap C = T_0^R O$" (a cone against a subspace) is read through the linearity of the chart image of T_0M.

Definition 9.3.8 (2017: 9.9) (V9.36) Chapter9/OrientationBoundary · MPolyfold.boundaryFrames. *For an oriented (M, o), $y \in \partial M$ with $d_M(y) = 1$: a basis $(a_1, \dots, a_{n-1})$ of $T_y\partial M$ is positive iff $(e, a_1, \dots, a_{n-1})$ is positive, e outward.* Linear algebra first: the convention orients a hyperplane K Chapter9/OrientationBoundary · exists_boundary_orientation, by the determinant criterion Chapter9/OrientationBoundary · exists_basis_orientation_iff_det_pos Chapter9/OrientationBoundary · det_cons_smul_add. In a tangent set: for $K \subseteq T_yM$ with $(m-1)$-dimensional chart image and $e \notin K$, the frames orient K Chapter9/OrientationBoundary · MPolyfold.isOrientedAt_boundaryFrames, and $e \mapsto ce + k$, $c > 0$, $k \in K$, does not change them Chapter9/OrientationBoundary · MPolyfold.boundaryFrames_eq; both orientations occur, on a graph Chapter9/OrientationBoundary · exists_boundaryFrames_graph. $T_y\partial M$ and e are data in this definition. That $T_y\partial M = T_y^R M$ and the outward half-space are determined by M through the cones C_yM, and that the resulting orientation is continuous along the stratum $\{d_M = 1\}$, is proved in §IX.30 (gap G.103, closed); row V9.36 is now explicit.

(9.11) and Proposition 9.3.9 (V9.37), new in the 2021 edition. Split the oriented sum at y by $\ell = d_{M_i}(y)$ Chapter9/OrientationBoundary · EpGroupoid.degreePart Chapter9/OrientationBoundary · EpGroupoid.degreePart_orientedSum; by Lemma 9.3.7 tangent sets of different degree never coincide Chapter9/OrientationBoundary · MPolyfold.HasSubDegree Chapter9/OrientationBoundary · MPolyfold.SubmanifoldOrientation.hasSubDegree_tangent_iff, so two oriented structures with the same oriented sum at y have the same degree-ℓ parts for every ℓ Chapter9/OrientationBoundary · EpGroupoid.eq_9_11. Applying a boundary operation $T_y(M, o) \mapsto T_y(\partial M, o_{\partial M})$, a function `bd` of the oriented tangent set, to the degree-1 part gives (9.12), which therefore does not depend on the structure Chapter9/OrientationBoundary · EpGroupoid.proposition_9_3_9. **Definition 9.3.10 (2017: 9.11)** (V9.38) is (9.12) with 0 off the support Chapter9/OrientationBoundary · EpGroupoid.boundaryLift; the condition $y \in \partial M_i$ is implied by $d_{M_i}(y) = 1$. The operation `bd` is now built from the sheet, and (9.12) and Proposition 9.3.9 hold with it Chapter9/BoundaryOperation · EpGroupoid.proposition_9_3_9_boundaryOp Chapter9/BoundaryOperation · EpGroupoid.boundaryOrientation; the continuity of $o_{\partial M}$ along ∂M and its extension to the faces (Figure 9.1) are §IX.30. Remark 9.3.11, on the non-tame case, has no formal content.

IX.17 §9.4: essential points and sets of measure zero (Definitions 9.4.1, 9.4.5, 9.4.7, Lemmas 9.4.2–9.4.8 (2017: 9.12–9.14, 9.11–9.15))

For Mathlib manifolds. Definitions 9.4.1 and 9.4.5 are about a smooth finite-dimensional manifold M with boundary and corners, formalized for Mathlib manifolds with corners. *Definition 9.4.1 (1)* (V9.39): $T_z^K M$ is the span of the unit limits $\varphi(z_k)/|\varphi(z_k)|$, $z_k \to z$ in $K \setminus \{z\}$, in a chart φ centred at z. In a chart it is the span of Mathlib's tangent cone of the chart image of K Chapter9/BranchingGeometryManifold · chartImage Chapter9/BranchingGeometryManifold · span_tangentConeAt_chartImage_eq_map Chapter9/BranchingGeometryMeasure · span_unitDirections Chapter9/BranchingGeometryMeasure · unitDirections Chapter9/BranchingGeometryManifold · relTangent, and a chart change maps it by the derivative Chapter9/BranchingGeometryManifold · relTangent_eq_map, which is the text's "independent of the choice of φ". *Definition 9.4.1 (2)*: z is essential if it is a limit of points of K where $T^K M$ is everything Chapter9/BranchingGeometryManifold · relTangent_eq_top_iff Chapter9/BranchingGeometryManifold · fullSet Chapter9/BranchingGeometryManifold · essentialSet Chapter9/BranchingGeometryManifold · essentialSet_eq. For two crossing lines in $\mathbb{R}^2$ the essential set is $\{0\}$ Chapter9/BranchingGeometryManifold · crossLines Chapter9/BranchingGeometryManifold · essentialSet_crossLines Chapter9/BranchingGeometryManifold · nonEssential_crossLines. *Lemma 9.4.2 (2017: 9.11)* (V9.40), "obvious from the definition": K^e is a closure taken in K Chapter9/BranchingGeometryManifold · lemma_9_4_2 Chapter9/BranchingGeometryManifold · lemma_9_

4_2_open. *Definition 9.4.5 (2017: 9.13)* (V9.43) Chapter9/BranchingGeometryManifold · IsMeasureZero: null in every chart; countable unions Chapter9/BranchingGeometryManifold · isMeasureZero_iUnion, a chart cover suffices Chapter9/BranchingGeometryManifold · isMeasureZero_of_forall_mem, and $\mathbb{R}^2$ is not null Chapter9/BranchingGeometryManifold · not_isMeasureZero_univ. *Lemma 9.4.6 (2017: 9.14)* (V9.44) Chapter9/BranchingGeometryManifold · lemma_9_4_6, "proved similarly as Lemma 2.8 in [57]": *Step 1.* At a point where $T_z^K M \neq T_z M$ there is a unit direction v off the span, and points of K near z lie outside a cone around v Chapter9/BranchingGeometryMeasure · eventually_abs_le_of_tangentConeAt. *Step 2.* A cone has positive density at its vertex Chapter9/BranchingGeometryMeasure · exists_pos_measure_cone_lt, so z is not a Lebesgue density point of K; by Lebesgue's density theorem the set of such z is null Chapter9/BranchingGeometryMeasure · addHaar_setOf_span_tangentConeAt_ne_top Chapter9/BranchingGeometryManifold · isMeasureZero_setOf_relTangent_ne_top. *Step 3.* A non-essential point has a neighbourhood in K of such points, by Lemma 9.4.2. The statement holds for every K, not only for $K(i,i')$.

For sheets in an M-polyfold. The sheets M_i are submanifolds of an M-polyfold, which in general carry no Mathlib manifold structure (a tame sheet does, §IX.16). So the essential points and null sets of the sheets are the data of a `SheetGeometry` Chapter9/BranchingGeometry · MPolyfold.SheetGeometry, with Lemma 9.4.4 (`ess_comm`), Lemma 9.4.6 (`isNull_diff_ess`) and the note of Definition 9.4.7 (`submanifoldTangent_eq`) as fields; it was first witnessed by pieces of graphs in $\mathbb{R}^2$, with the essential sets and null sets of the Mathlib part read in the chart $z \mapsto z_0$ Chapter9/BranchingGeometry · graphSheets Chapter9/BranchingGeometry · graphSheetGeometry. It is now built on the n-dimensional submanifolds of every M-polyfold with no hypothesis, Definitions 9.4.1 and 9.4.5 being read in the M-polyfold charts as in the text's proof of Lemma 9.4.4 Chapter9/SheetEssential · sheetGeometry (§IX.28; gap G.105, closed). So Lemma 9.4.8 and Propositions 9.4.9, 9.4.10 hold for every n-dimensional Θ with no sheet-geometry hypothesis Chapter9/SheetGeometryFree · lemma_9_4_8_of_isNDimensional Chapter9/SheetGeometryFree · proposition_9_4_9_of_isNDimensional Chapter9/SheetGeometryFree · proposition_9_4_10_of_isNDimensional.

Lemma 9.4.4 (2017: 9.13) (V9.42). *Essential for $K(i,i') \subseteq M_i$ iff for $K(i,i') \subseteq M_{i'}$*, "left to the reader". **As we read it, it needs sheets of one dimension** Chapter9/BranchingGeometry · lemma_9_4_4_mixed_dim: $\mathbb{R} \times 0$ as a subset of $\mathbb{R}$ is essential at every point, as a subset of $\mathbb{R}^2$ nowhere, since its relative tangent space is a line. For an n-dimensional Θ the text's reduction to $T_0^D N$ in a chart applies, and is now proved for n-dimensional submanifolds of every M-polyfold Chapter9/SheetEssentialChart2021 · lemma_9_4_4_chart and for the sheets of every structure of an n-dimensional Θ Chapter9/SheetMeasure · lemma_9_4_4_of_isNDimensional (§IX.28).

Definition 9.4.7 (2017: 9.14) (V9.45). $i \sim_y i'$ through a chain of links $y \in K(i_{p-1}, i_p)^e$ Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.IsLink Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.YEquiv is an equivalence relation Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.equivalence_yEquiv Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.ySetoid; equivalent sheets have the same tangent set at y Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.submanifoldTangent_eq_of_yEquiv; $\#P_y$ is Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.numClasses.

Lemma 9.4.8 (2017: 9.15) (V9.46) Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.lemma_9_4_8. $\{y \in M_U \mid \#P_y \geq 2\}$ *is null.* "Null in M_U" is null in every sheet through the point Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.IsNullIn. The text decomposes M_U by (I_y, P_y) and concludes that the bad part lies in $\bigcup_{j,j'} K(j,j')^{ne}$. As we read it, $K(j,j')^{ne}$ is null only in M_j and $M_{j'}$; inside a sheet M_i through y the proof uses $K(i,j)^{ne}$ for j not y-equivalent to i: if y had two classes, the class of i omits some $j \in I_y$, so $y \in K(i,j)$ is not essential. Hence $M_U \setminus M_U^*$ is null Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.MStar Chapter9/BranchingGeometry · MPolyfold.

SheetGeometry.isNullIn_diff_MStar.

IX.18 Property (T), Propositions 9.4.9 and 9.4.10 (2017: 9.5 and 9.6)

Property (T) (V9.41) Chapter9/BranchingGeometry · EpGroupoid.OrientedBranchingStructure.PropertyT: the orientation relation of two sheets with the same tangent space is the same at every common point with the same tangent space; the first structure of Example 9.3.5 has it Chapter9/BranchingGeometry · propertyT_example935B1. Under (T) the sign map $K(i,i')^e \to \{\pm 1\}$ is constant Chapter9/BranchingGeometry · EpGroupoid.tangent_eq_iff_of_mem_ess. **Lemma 9.4.3** (V9.41) Chapter9/PropertyTShrinking2021 · lemma_9_4_3 Chapter9/PropertyTShrinking2021 · lemma_9_4_3_propertyT. *Every oriented local branching structure has Property (T) after restriction to a smaller open $U'(x)$* (gap G.104, closed). **The text's proof** argues along sequences of points converging to x. **The formalized proof** finds, for each of the finitely many pairs (i,i'), an open neighbourhood of x on which the pair satisfies (T), and intersects Chapter9/PropertyTShrinking2021 · SubmanifoldOrientation.exists_isOpen_pairT Chapter9/PropertyTShrinking2021 · restrict Chapter9/PropertyTShrinking2021 · propertyT_restrict_iff. *Case 1, different dimensions:* two submanifolds with the same tangent set at a point have the same dimension there Chapter9/PropertyTShrinking2021 · HasDimAt.eq_of_submanifoldTangent_eq, so (T) asks nothing of such a pair. *Case 2, dimension 0:* a point where a submanifold is 0-dimensional is isolated in it, by the chord estimate with vanishing derivative Chapter9/PropertyTShrinking2021 · HasDimAt.exists_isOpen_eq_of_mem. *Case 3, equal tangent spaces at x:* where the tangent spaces agree, the relative orientation is the sign of a frame determinant, locally constant by the level-1 continuity (§IX.15) Chapter9/OrientationRn · MPolyfold.SubmanifoldOrientation.exists_isOpen_tangent_eq_iff. *Case 4, different tangent spaces at x:* they stay different nearby, since a continuous frame field of one, written in the chart, has a nonzero minor against the other Chapter9/PropertyTShrinking2021 · exists_chartTangent_field Chapter9/PropertyTShrinking2021 · exists_frameDet_ne_zero Chapter9/PropertyTShrinking2021 · exists_isOpen_submanifoldTangent_ne, so after shrinking (T) is empty for the pair.

Proposition 9.4.9 (2017: 9.5) (V9.47) Chapter9/BranchingGeometry · EpGroupoid.proposition_9_4_9. *Off a null set $M_U = M_U^* = \bigsqcup_J M_U^J$, and on M_U^J: $\Theta = \sigma_J$, $T_\Theta = \sigma_J T^J$, $\hat{T}_\Theta = a_J(T^J, o_J^a) + b_J(T^J, o_J^b)$, $a_J + b_J = \sigma_J$, $o_J^a = -o_J^b$. Step 1.* The null set is Lemma 9.4.8; the pieces are the level sets of $y \mapsto I_y$ Chapter9/BranchingGeometry · MPolyfold.SheetGeometry.MStarPart. *Step 2.* On M_U^J all sheets of J are y-equivalent, so they have one tangent set T^J and $T_\Theta(y) = \sigma_J T^J$ Chapter9/BranchingGeometry · EpGroupoid.LocalBranchingStructure.tangentValue_eq_sum, which uses the independence of Theorem 9.2.1. *Step 3.* By (T) the orientations of the sheets of J at y fall into two opposite classes; $o_J^a = -o_J^b$ is "$o_J^a \neq o_J^b$ on the same tangent set", since it has exactly two orientations Chapter9/BranchingGeometry · MPolyfold.OrTangent.eq_or_eq_or_eq_of_isOrientedAt Chapter9/BranchingGeometry · MPolyfold.exists_ne_isOrientedAt; if one class is empty its orientation is the other one. The footnote's "measure zero" in M_U refers forward to Definition 9.5.1 and Lemma 9.5.2 (p. 437), consistently as we read it.

Proposition 9.4.10 (2017: 9.6) (V9.48) Chapter9/BranchingGeometry · EpGroupoid.proposition_9_4_10. *Two oriented structures on $U(x)$ with (a) the same weight sums and (b) the same oriented sums agree off a null set, piece by piece, as in (1)–(5).* **The text** takes the union B'' of the two structures, which describes 2Θ, applies Proposition 9.4.9 to B, B', B'' and intersects. **The formalized proof** takes $M_U^\dagger = M_U''^*$ for the union only, not intersected with M_U^* and $M_U'^*$, which (1)–(5) do not need. The pieces A_p are cut out by the finitely many values of $y \mapsto (I_y, I'_y, J_+(y), J'_+(y))$, with $J_\pm(y)$ the two orientation classes at y, so Property (T) is not used. The two structures of Example 9.3.5, all signs $+$, satisfy (a) and (b) Chapter9/BranchingGeometry · example935B1 Chapter9/BranchingGeometry · example935B2 Chapter9/BranchingGeometry · example935_hypotheses_9_4_10 Chapter9/BranchingGeometry · example935_MU_eq; at the origin G^{++} and G^{--} are tangent but

not 0-equivalent, so the set of Lemma 9.4.8 is not empty `Chapter9/BranchingGeometry · example935_two_le_numClasses`.

IX.19 §9.5: sets of measure zero and the σ-algebras $L(S)$, $L(\partial S)$ (Definitions 9.5.1, 9.5.3, 9.5.14, Lemma 9.5.2 (2017: Definitions 9.15–9.17, Lemma 9.16))

The setting of §9.5. Θ is oriented, tame, compact and n-dimensional, and $S = |\mathrm{supp}(\Theta)|$. Measure zero in a sheet M_i is that of Definition 9.4.5, which the project first had for Mathlib manifolds only (§IX.17). So, as in §9.4, the null sets of the sheets are data, now instantiated on every M-polyfold by the n-dimensional Hausdorff measure of the chart images (§IX.28; gap G.106, closed): a system `SheetNullSets` on a class $\mathcal{S}$ of sheets `Chapter9/Measure · SheetNullSets`, with null sets closed under subsets, countable unions `Chapter9/Measure · SheetNullSets.isNull_iUnion_countable` and finite unions `Chapter9/Measure · SheetNullSets.isNull_union`, local, induced alike by two sheets of $\mathcal{S}$ on their overlap (`isNull_transfer`), and a nonempty sheet not null in itself. A §9.4 sheet geometry with these properties is a `SheetMeasureGeometry` `Chapter9/Measure · MPolyfold.SheetMeasureGeometry` `Chapter9/Measure · MPolyfold.SheetMeasureGeometry.toSheetNullSets`, and then null preimages are §9.4's "null in M_U" `Chapter9/Measure · EpGroupoid.LocalBranchingStructure.hasNullPreimages_iff_isNullIn`. *The covering criterion* `Chapter9/Measure · SheetNullSets.isNull_of_cover`: a subset C of a sheet $N \in \mathcal{S}$ is null in N if near each of its points it is covered by finitely many sheets of $\mathcal{S}$ in which it is null; by locality and the transfer property.

Definition 9.5.1 (2017: 9.15) (V9.49) `Chapter9/Measure · EpGroupoid.IsMeasureZeroSupp`. $A \subseteq |X|$ has measure zero if every $x \in \mathrm{supp}(\Theta)$ has a tame local branching structure (Definition 9.3.6, the text's "suitable $U(x)$") with sheets in $\mathcal{S}$ whose preimages $M_i \cap \pi^{-1}(A)$ are null in M_i `Chapter9/Measure · EpGroupoid.LocalBranchingStructure.HasNullPreimages`. The variants ask this of some local branching structure `Chapter9/Measure · EpGroupoid.IsMeasureZeroSuppAny`, or of every structure with sheets in $\mathcal{S}$ `Chapter9/Measure · EpGroupoid.IsMeasureZeroSuppAll`; the standing assumption is that tame structures with sheets in $\mathcal{S}$ exist `Chapter9/Measure · EpGroupoid.HasTameSheetsIn`. Compactness and orientation are not used.

Lemma 9.5.2 (2017: 9.16) (V9.50) `Chapter9/Measure · EpGroupoid.lemma_9_5_2`. *The notion does not depend on the choice of the local branching structures.* **The text** cites the literature, without proof. **The formalized proof.** *Step 1, the core* `Chapter9/Measure · EpGroupoid.isMeasureZeroSuppAll_of_any`. Suppose some structure at every point has null preimages of A, and let B' be any structure with sheets in $\mathcal{S}$ and M'_j one of its sheets. Each $z \in M'_j \cap \pi^{-1}(A)$ lies in the support, so a structure B at z with null preimages exists. Near z, $M'_j \subseteq \mathrm{supp}(\Theta) \cap U_B = \bigcup_i M_i$, so $M'_j \cap \pi^{-1}(A)$ is covered near z by the finitely many M_i, in which it is null. The covering criterion gives that it is null in M'_j. *Step 2.* A tame structure is a structure `Chapter9/Measure · EpGroupoid.isMeasureZeroSuppAny_of_isMeasureZeroSupp`, and under the standing assumption every point has a tame one with sheets in $\mathcal{S}$; the three notions agree. *Step 3.* The sets of measure zero form a σ-ideal `Chapter9/Measure · EpGroupoid.isSigmaIdeal_isMeasureZeroSuppAll` `Chapter9/Measure · EpGroupoid.isSigmaIdeal_isMeasureZeroSupp`, and $S \neq \emptyset$ is not null, since a sheet through a point of the support is not null in itself `Chapter9/Measure · EpGroupoid.not_isMeasureZeroSuppAny_orbitSupp` `Chapter9/Measure · EpGroupoid.not_isMeasureZeroSupp_orbitSupp`.

The transfer property, as we read it, needs one dimension `Chapter9/Measure · isNull_transfer_mixed_dim`. Step 1 uses that a set null in the sheets M_i is null in M'_j on their overlap. For sheets of different dimensions this does not hold: the axis $\mathbb{R} \times 0$ has Lebesgue measure zero in the sheet $\mathbb{R}^2$ and is not null

in itself, a 1-dimensional sheet; so no single system contains the planar null sets and those of graphs. The lemma is therefore proved for structures whose sheets lie in one class, as do the n-dimensional structures of an n-dimensional Θ. That *every* structure of an n-dimensional Θ has n-dimensional sheets is now proved on every ep-groupoid, from the independence of Theorem 9.2.1 `Chapter9/SheetMeasure · isOfDim_of_isNDimensional`, so for n-dimensional Θ Lemma 9.5.2 holds as printed (§IX.28; row V9.50 explicit). With the Hausdorff null sets the transfer across dimensions does not hold as we read it either: the axis of $\mathbb{R}^2$ has 2-dimensional and not 1-dimensional measure zero `Chapter9/SheetMeasure · isHNull_mixed_dim`.

Definition 9.5.3 (2017: 9.16) and the remark after it (V9.51). *Step 1, a general fact.* For a family $\mathcal{N}$ of subsets, the σ-algebra generated by the Borel sets and $\mathcal{N}$ `Chapter9/Measure · borelNullSigma Chapter9/Measure · borel_le_borelNullSigma Chapter9/Measure · measurableSet_borelNullSigma_of_mem` is, if $\mathcal{N}$ is a σ-ideal `Chapter9/Measure · IsSigmaIdeal`, the family $\{A \mid A \,\Delta\, B \in \mathcal{N} \text{ for a Borel } B\}$ `Chapter9/Measure · borelNullCompletion Chapter9/Measure · measurableSet_borelNullSigma_iff`: that family is a σ-algebra, by $\bigcup_k A_k \,\Delta\, \bigcup_k B_k \subseteq \bigcup_k (A_k \,\Delta\, B_k)$ `Chapter9/Measure · symmDiff_iUnion_subset`, contains the Borel sets and $\mathcal{N}$, and lies in every σ-algebra containing both. *Step 2.* $L(S)$ is this σ-algebra on the subspace S for the sets of measure zero `Chapter9/Measure · EpGroupoid.measureZeroSets Chapter9/Measure · EpGroupoid.lebesgueSigma`, a σ-ideal under the standing assumption `Chapter9/Measure · EpGroupoid.isSigmaIdeal_measureZeroSets`. *Step 3.* The text's remark that $L(S)$ is obtained by adding the sets of measure zero is read as the completion: $K \in L(S)$ iff $K \,\Delta\, B$ has measure zero for a Borel B `Chapter9/Measure · EpGroupoid.remark_9_5_3`; sets of measure zero belong to $L(S)$ `Chapter9/Measure · EpGroupoid.measurableSet_lebesgueSigma_of_isMeasureZeroSupp`. The form $K = B \cup N$ would need Borel null hulls of null sets, which an abstract system does not provide.

Definition 9.5.14 (2017: 9.17) and the paragraph before it (V9.52). $\partial S = |\mathrm{supp}(\partial\Theta)| \subseteq S$ `Chapter9/Measure · EpGroupoid.orbitSupp_boundaryTheta_subset`. $(n-1)$-dimensional measure zero in the boundaries ∂M_i `Chapter9/Boundary · MPolyfold.submanifoldBoundary` is a second system on a class of boundaries, and K has measure zero in ∂S if at every point of $\mathrm{supp}(\partial\Theta)$ a tame structure has boundary preimages null in the ∂M_i `Chapter9/Measure · EpGroupoid.IsMeasureZeroBoundary Chapter9/Measure · EpGroupoid.IsMeasureZeroBoundaryAll`. *"A well-defined notion"* `Chapter9/Measure · EpGroupoid.isMeasureZeroBoundaryAll_of`: the proof of Lemma 9.5.2 applies to the boundaries. By the local formula for $\partial\Theta$ (Proposition 9.2.15), which holds for every structure given the independence of Theorem 9.2.1, a point of $\partial M'_j$ lies in $\mathrm{supp}(\partial\Theta)$, and a point of $\mathrm{supp}(\partial\Theta)$ lies in some ∂M_i of any structure at it, a positive sum having a nonzero term `Chapter9/Measure · EpGroupoid.exists_mem_of_sum_pos`; so the boundary preimage in $\partial M'_j$ is covered near each point by the ∂M_i of a structure with null boundary preimages. $L(\partial S)$ is the σ-algebra generated by the Borel sets of ∂S and these sets `Chapter9/Measure · EpGroupoid.boundaryMeasureZeroSets Chapter9/Measure · EpGroupoid.lebesgueSigmaBoundary`. The $(n-1)$-dimensional null sets themselves, a witness with $\partial S \neq \emptyset$ and the σ-algebra $L(\partial S)$ built with them are §IX.34 (gap G.108, closed).

Witnesses (V9.53). *Tools.* Measure zero of Definition 9.4.5 is local `Chapter9/Measure · isMeasureZero_image_of_local`, holds for subsingletons `Chapter9/Measure · isMeasureZero_of_subsingleton`, and on $\mathbb{R}^2$ is Lebesgue measure zero `Chapter9/Measure · isMeasureZero_rn2_iff`. On the trivial ep-groupoid of $\mathbb{R}^n$ every local branching structure restricts to a tame one, on the domain of a natural representation `Chapter9/Measure · exists_tameBranchingStructure_trivial_rn Chapter9/Measure · hasTameSheetsIn_trivial_rn`, and π is injective `Chapter9/Measure · injective_π_trivial_rn`. *Example 9.3.5.* The graph sheets of §9.4 carry a `SheetMeasureGeometry` `Chapter9/Measure · graphSheetMeasureGeometry Chapter9/Measure · graphNull`; for the Θ of the two graphs G^{++}, G^{--}, which touch at 0 `Chapter9/Measure · theta935 Chapter9/Measure · isBranchedEpSubgroupoid_theta935 Chapter9/Measure · hasTameSheetsIn_theta935 Chapter9/Measure · zero_mem_supp_theta935`, the point $|0|$ has measure zero `Chapter9/Measure · isMeasureZeroSupp_theta935_zero`, S does not `Chapter9/Measure · not_isMeasureZeroSupp_theta935`, and both are in $L(S)$ `Chapter9/Measure · lebesgueSigma_theta935`. *The plane.* For $\Theta = 1$ on $\mathbb{R}^2$,

with the open subsets of $\mathbb{R}^2$ as sheets and Lebesgue null sets Chapter9/Measure · planeSheets Chapter9/Measure · planeNull Chapter9/Measure · planeSheet Chapter9/Measure · isSmoothSubmanifold_univ_rn2 Chapter9/Measure · thetaPlane Chapter9/Measure · isBranchedEpSubgroupoid_thetaPlane Chapter9/Measure · mem_supp_thetaPlane Chapter9/Measure · hasTameSheetsIn_thetaPlane, some member of $L(S)$ is not Borel Chapter9/Measure · exists_mem_lebesgueSigma_not_borel_thetaPlane: every subset of the null axis is in $L(S)$, there are $2^{\mathfrak{c}}$ of them, and only $\mathfrak{c}$ Borel sets.

IX.20 §9.5: the isotropy factors (Lemmas 9.5.9–9.5.11 and Proposition 9.5.13 (2017: Lemmas 9.18, 9.19))

The measures μ_ω of Theorems 9.5.4 and 9.5.5 are local weighted integrals of a form over the sheets, divided by $\#G_x$ or $\#G_x^{\mathrm{eff}}$. This subsection gives what the proofs of Lemmas 9.5.9–9.5.11 and Proposition 9.5.13 rest on, the orders of the isotropy groups and the decompositions of the preimages; the measure identities themselves are stated and proved in §IX.31 (Lemmas 9.5.7, 9.5.9–9.5.11, Proposition 9.5.13 (1)) and §IX.33 (Proposition 9.5.13 (2)), and rows V9.54–V9.56 are explicit.

Lemma 9.5.9 (2017: 9.18) (V9.54). **The text's proof** identifies $H = \{g \mid g * y = y\}$ with G_y, writes $G = \bigcup_{r\in R} rH$, chooses $V(y)$ invariant under H and disjoint from its other translates, notes that $\tilde{M}_j = V \cap M_j$ is a branching structure on V, decomposes the preimage of K as $\bigcup_r \varphi_r(\tilde{K})$, and uses $\#R = \#G/\#H$. **The formalized part.** *Step 1,* $\#R \cdot \#G_y = \#G_x$ Chapter9/MeasureEffective · EpGroupoid.NaturalRep.card_quotient_stabilizer_mul_card_isotropy: the stabilizer H of y for the action of G_x on $U(x)$ is isomorphic to G_y by the natural representation (Chapter 7) Chapter9/MeasureEffective · EpGroupoid.NaturalRep.mem_stabilizer_iff_Φ, and R is `Quotient.out` on G_x/H. *Step 2, the slice* Chapter9/MeasureEffective · EpGroupoid.NaturalRep.exists_slice: inside any neighbourhood of y there is an open V with $\varphi_g(V) = V$ for $g \in H$ and $\varphi_g(V) \cap V = \emptyset$ for $g \notin H$: separate y from $\varphi_g(y) \neq y$ for the finitely many $g \notin H$, and make the neighbourhood H-invariant. *Step 3, the preimage.* $|\varphi_g(z)| = |z|$ Chapter9/MeasureEffective · EpGroupoid.NaturalRep.π_Φ, so φ_g maps $M_U = \mathrm{supp}(\Theta) \cap U$ to itself, Θ being a functor Chapter9/MeasureEffective · EpGroupoid.NaturalRep.mapsTo_Φ_MU; for $K \subseteq |M_U \cap V|$, $M_U \cap \pi^{-1}(K) = \bigcup_g \varphi_g(M_U \cap V \cap \pi^{-1}(K))$ Chapter9/MeasureEffective · EpGroupoid.NaturalRep.MU_inter_preimage_eq_iUnion, the same with g running over the representatives r Chapter9/MeasureEffective · EpGroupoid.NaturalRep.MU_inter_preimage_eq_iUnion_quotient, and the union over R is disjoint Chapter9/MeasureEffective · EpGroupoid.NaturalRep.pairwise_disjoint_image_Φ_out. The restriction $\tilde{M}_j$ is §IX.3's `restrictAt`: the project's structures pass through their base point, so at y the sheets through y are kept.

Lemma 9.5.10 (V9.55), new in the 2021 edition. *Step 1.* $\#T_x \cdot \#G_x^{\mathrm{eff}} = \#G_x$ for the subgroup T_x acting trivially near x Chapter9/MeasureEffective · EpGroupoid.card_effIsotropy_mul_card_trivialSubgroup. *Step 2.* Under LUC for the given $U(x)$ (Definition 7.2.18, `NaturalRep.HasLUC`), T_x is the kernel of the representation Chapter9/MeasureEffective · EpGroupoid.NaturalRep.kerΦ_eq_trivialSubgroup, hence lies in every stabilizer Chapter9/MeasureEffective · EpGroupoid.NaturalRep.kerΦ_le_stabilizer, and corresponds to T_y under $H \cong G_y$ Chapter9/MeasureEffective · EpGroupoid.NaturalRep.stabilizerEquivIsotropy_mem_trivialSubgroup_iff, so $\#T_y = \#T_x$ Chapter9/MeasureEffective · EpGroupoid.NaturalRep.card_trivialSubgroup_eq. *Step 3, (9.23).* Dividing Step 1 of Lemma 9.5.9 by $\#T_x = \#T_y$ gives $\#R \cdot \#G_y^{\mathrm{eff}} = \#G_x^{\mathrm{eff}}$ Chapter9/MeasureEffective · EpGroupoid.NaturalRep.card_quotient_stabilizer_mul_card_effIsotropy.

Lemma 9.5.11 (2017: 9.19) (V9.56). The orders $\#G_x$ and $\#G_x^{\mathrm{eff}}$ are invariant along morphisms, by conjugation with φ (Lemma 7.2.6) Chapter9/MeasureEffective · EpGroupoid.card_isotropy_eq_of_mor Chap-

ter9/MeasureEffective · EpGroupoid.card_effIsotropy_eq_of_mor. A functor is constant on orbits Chapter9/MeasureEffective · EpGroupoid.IsFunctorial.eq_of_π_eq, so for structures on U, U' and any map $\hat{\varphi}$ of U onto U' with $|\hat{\varphi}(z)| = |z|$, $|M_U| = |M_{U'}|$ Chapter9/MeasureEffective · EpGroupoid.image_π_MU_eq; the maps φ_g of a natural representation are such maps Chapter9/MeasureEffective · EpGroupoid.NaturalRep.Φ_hyps. The "change of variables" in the integrals is the invariance of the sheet integration under the local sc-diffeomorphism $\hat{\varphi}$, and gives Lemma 9.5.11 as a measure identity in §IX.31.

Proposition 9.5.13 (V9.57), new in the 2021 edition. *(1)* For effective X, $T_x = \{1\}$, so $\#G_x^{\mathrm{eff}} = \#G_x$ Chapter9/MeasureEffective · EpGroupoid.card_effIsotropy_eq_of_isEffective and the normalizing factors of the two integrals agree. *(2)* The reduced ep-groupoid X_R (Chapter 7) has the object M-polyfold of X, with Hausdorff and paracompact morphism space as instances (Hausdorff under LUC); functors Chapter9/MeasureEffective · EpGroupoid.isFunctorial_reduced_iff and local branching structures Chapter9/MeasureEffective · EpGroupoid.LocalBranchingStructure.toReduced of X and X_R coincide, and $\#G_x^{\mathrm{eff}} = \#G_x^R = \#(G_x^R)^{\mathrm{eff}}$ Chapter9/MeasureEffective · EpGroupoid.card_effIsotropy_eq_reduced. The identity of the integrals, $\oint_{\hat{\Theta}} \omega = \int_{\hat{\Theta}_R} \omega$, is §IX.33 (row V9.57 restated).

IX.21 Appendix §9.6.1: Lemmas 9.6.1 and 9.6.2, Definition 9.6.3 and Lemma 9.6.4

In place of "measure zero." The text's proofs of Lemmas 9.6.1, 9.6.2 and 9.6.4 remove sets of smaller dimension or not containing a sheet near the point, "of measure zero", and move a point slightly. The formalization uses a topological covering lemma instead, with no Lebesgue measure and no Baire category. *Step 1.* If $A \cap W \subseteq N$ for an open $W \ni a$, then $\dim_a A \le \dim_a N$, by the inclusion of the chart tangent spaces Chapter9/Appendix · MPolyfold.HasDimAt.le_of_inter_subset. *Step 2*, the covering lemma Chapter9/Appendix · MPolyfold.exists_mem_forall_notMem: a nonempty open piece of a k-dimensional submanifold is not covered by finitely many submanifolds of smaller dimension closed in an open set, by induction on the family: removing one closed set of smaller dimension leaves a nonempty open piece, by Step 1. *Step 3*, "moving z slightly": a point of the piece off all the given sets Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.IsGeneric Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.exists_isGeneric.

Lemma 9.6.1 (V9.58) Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.lemma_9_6_1. *Two structures at x have the same top dimension* Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.topDim. If the first has top dimension k and the second $\ell < k$, a generic point of a k-dimensional sheet of the first has $\Theta > 0$ by the first structure and $\Theta = 0$ by the second. So $\dim_\Theta(x)$ is well defined Chapter9/Appendix · EpGroupoid.localTopDim Chapter9/Appendix · EpGroupoid.localTopDim_eq, $-\infty$ off the support Chapter9/Appendix · EpGroupoid.localTopDim_eq_bot.

Lemma 9.6.2 (V9.59) Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.lemma_9_6_2. *The unions M_U^k of the top-dimensional sheets agree on $U \cap U'$* Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.topUnion Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.mem_topUnion_iff_of_mem: a generic point of $M_U^k \setminus M_{U'}^k$ would have $\Theta > 0$ by the first structure and, off the lower-dimensional sheets of the second, $\Theta = 0$.

Definition 9.6.3 (V9.60) Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.IsTopGoodPoint Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.IsTopBadPoint, as in the text. At points top-good for both structures the top parts agree, with no hypothesis Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.dimPart_topDim_eq_of_isTopGoodPoint: near such a point the top part is $\sigma \cdot 1_M$ for both, and σ is read off Θ at a generic point of M.

Lemma 9.6.4 (V9.61). *Top-goodness does not depend on the structure.* **The text's proof**: near a top-good z, $\Theta = \sigma \cdot \delta_M + \Theta_0 + \cdots + \Theta_{k-1}$; a point of M near z off the lower-dimensional sets has $\Theta = \sigma$, and "similarly as good points", z is top-good for the second structure. **As we read it, this needs that the top weight of the second structure at y is σ**, an argument the text does not give: the second structure could a priori have, through y, several top-dimensional sheets with tangent spaces that differ. **The formalized proof** makes this step the hypothesis `TopMultiplicity` Chapter9/Appendix · MPolyfold.TopMultiplicity: at a point where Θ equals σ on generic points of a k-dimensional sheet, the top weight of any structure is σ. Under it the lemma holds Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.lemma_9_6_4 Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.isTopBadPoint_iff, the top parts agree on $U \cap U'$ Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.dimPart_topDim_eq_of_topMultiplicity, and Proposition 9.1.12 follows by the descending induction of p. 454: subtract the top parts Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.subOn and repeat Chapter9/Appendix · EpGroupoid.LocalBranchingStructure.dimPartsAgreeNear_of_topMultiplicity Chapter9/Appendix · EpGroupoid.proposition_9_1_12_of_topMultiplicity. Witnesses: $k = 0$ on every M-polyfold Chapter9/Appendix · MPolyfold.topMultiplicity_zero, and $k \geq n$ on $\mathbb{R}^n$, where an n-dimensional submanifold is a neighbourhood of each of its points Chapter9/Appendix · rnPolyfold_mem_nhds_of_hasDimAt Chapter9/Appendix · topMultiplicity_rn_of_le; so Proposition 9.1.12 holds on $\mathbb{R}^0$ and $\mathbb{R}^1$ unconditionally Chapter9/Appendix · proposition_9_1_12_rn_zero Chapter9/Appendix · proposition_9_1_12_rn_one. The step itself is proved from the graph representation in §IX.22 Chapter9/AppendixSlices · MPolyfold.topMultiplicityAt_of_hasGraphChartAt Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.lemma_9_6_4_of_hasGraphChartAt, and now on every M-polyfold Chapter9/GeneralCorollaries · topMultiplicityAt Chapter9/GeneralCorollaries · topMultiplicity, so Lemma 9.6.4 holds for every ep-groupoid Chapter9/GeneralCorollaries · lemma_9_6_4_general Chapter9/GeneralCorollaries · isTopBadPoint_iff_general. In the proof the top-good point is called z and then y.

IX.22 Proposition 9.6.5, the formula on p. 457, and the proof of Proposition 9.1.12

Proposition 9.6.5 (V9.62) Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.proposition_9_6_5. *At a top-bad x, a class Ξ of top-dimensional indices with one tangent space splits as $I^1 \sqcup \cdots \sqcup I^p$ with sequences of top-good points $x_j^e \to x$ lying on M_i exactly for $i \in I^e$.* In (1) the text writes "$I_k = I^1 \sqcup \cdots \sqcup I^p$"; the I^e being subsets of Ξ, it reads as $\Xi = I^1 \sqcup \cdots \sqcup I^p$. **The slice form.** Under `HasGraphChartAt` at x, for every class and every neighbourhood W of x there is a finite top slice in W Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.IsTopSlice: it meets each sheet of the class once, misses the other top-dimensional sheets and all lower-dimensional ones, using a generic slice (§IX.9). Top slices in every W replace the top-good sequences.

The formula on p. 457 Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.dimPart_topDim_eq_sum_slices. $\Theta_k(x) = \sum_\Xi \sum_{y \in \text{slice}} \Theta(y)$; for one class the slice gives $\sum_{i \in \Xi} \sigma_i$ Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.sum_class_eq_sum_of_isTopSlice. The text's $\Theta_k(x_e^k)$ uses points x_e^k not introduced, presumably points x_j^e of the sequences. **The independence of the right-hand side**, which the text asserts while Ξ, I^e and x^e come from the first structure, is an argument the text does not give. It is proved by choosing one slice for the sheets of both structures, off all lower-dimensional sets of both, so that both class weights are the same sum of values of Θ Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.sum_class_eq_of_hasGraphChartAt Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.dimPart_topDim_eq_of_hasGraphChartAt. The

same grouping proves `TopMultiplicityAt` Chapter9/AppendixSlices · MPolyfold.TopMultiplicityAt Chapter9/AppendixSlices · MPolyfold.topMultiplicity_of_hasGraphChartAt, on $\mathbb{R}^m$ in all dimensions Chapter9/AppendixSlices · MPolyfold.topMultiplicity_rn. A per-dimension graph representation is not enough here: the lower-dimensional sheets through y must be avoided in the chart in which the top sheets are graphs, which is why one chart for all dimensions was asked. One cone per tangent space in that chart suffices, since the slice for a class only uses the cone of that class; with this change the slices exist at every point of every M-polyfold Chapter9/GeneralCorollaries · exists_slice_of_classGraphChart Chapter9/GeneralCorollaries · exists_generic_slice_general, and Proposition 9.6.5 and the formula on p. 457 hold for every ep-groupoid Chapter9/GeneralCorollaries · proposition_9_6_5_general Chapter9/GeneralCorollaries · sum_class_eq Chapter9/GeneralCorollaries · dimPart_topDim_eq.

The proof of Proposition 9.1.12. With the top parts agreeing near x, subtract them from both structures and repeat in lower dimensions Chapter9/AppendixSlices · EpGroupoid.LocalBranchingStructure.dimPartsAgreeNear_of_hasGraphChartAt Chapter9/AppendixSlices · EpGroupoid.proposition_9_1_12_of_hasGraphChartAt; on $\mathbb{R}^m$ without hypothesis Chapter9/AppendixSlices · EpGroupoid.proposition_9_1_12_rn, and on every ep-groupoid Chapter9/GeneralCorollaries · LocalBranchingStructure.dimPartsAgreeNear Chapter9/GeneralCorollaries · proposition_9_1_12. "This completes the proof of Proposition 9.6.5" (p. 457) refers to Proposition 9.1.12, Proposition 9.6.5 being stated without proof.

IX.23 Witnesses, counterexamples, and the hypotheses on $\mathbb{R}^m$

Hypotheses first taken on a general M-polyfold, now theorems. Each was proved on $\mathbb{R}^m$ first, and each now holds on every M-polyfold or every ep-groupoid; the statements under the hypotheses are kept. The independence of Theorem 9.2.1, `HasIndependentTangentSums`: first every Θ over $\mathbb{R}^m$ Chapter9/AppendixSlices · EpGroupoid.hasIndependentTangentSums_rn and the indicator of a point Chapter9/Tangent · hasIndependentTangentSums_indicator, now every Θ Chapter9/GeneralCorollaries · hasIndependentTangentSums. Tangent slices `HasTangentSlicesAt`: $\mathbb{R}^m$ Chapter9/TangentSlicesRn · MPolyfold.hasTangentSlicesAt_rn, $\mathbb{R}^0$ Chapter9/Tangent · hasTangentSlicesAt_rn_zero, every M-polyfold Chapter9/GeneralCorollaries · hasTangentSlicesAt. Graph charts: `IsGraphChartAt`, `HasGraphChartsAt`, `HasGraphChartAt`, `HasGraphBallAt` at every point of $\mathbb{R}^m$ (§IX.9); on every M-polyfold the class form at every point Chapter9/GeneralLevelZero · hasClassGraphChartAt and the one-cone and ball forms at interior points Chapter9/GeneralLevelZero · hasGraphChartAt_of_mem_interior. The local constancy of the dimension Chapter9/GeneralLevelZero · MPolyfold.hasLocallyConstantDimAt, invariance of domain Chapter9/GeneralLevelZero · hasDomainInvarianceAt and the level-1 continuity Chapter9/GeneralLevelZero · hasContinuousLevelOneOn: every M-polyfold. `TopMultiplicity`: every M-polyfold Chapter9/GeneralCorollaries · topMultiplicity. `HasOrientedGoodPointsAt`: every point Chapter9/GeneralBoundaryPoints · hasOrientedGoodPointsAt. `TangentBranchingHyp`: every Θ with $|X|$ paracompact Chapter9/TangentSubmanifoldSmooth · tangentBranchingHyp. `SheetGeometry`: the n-dimensional submanifolds of every M-polyfold Chapter9/SheetEssential · sheetGeometry, first graphs in $\mathbb{R}^2$ Chapter9/BranchingGeometry · graphSheetGeometry. Property (T): after shrinking, every oriented structure Chapter9/PropertyTShrinking2021 · lemma_9_4_3, first Example 9.3.5 Chapter9/BranchingGeometry · propertyT_example935B1. `SheetNullSets`: the Hausdorff null sets of every M-polyfold Chapter9/SheetNull · sheetNullSets, first graphs and open subsets of $\mathbb{R}^2$ Chapter9/Measure · graphSheetMeasureGeometry Chapter9/Measure · planeNull. `HasTameSheetsIn`: every structure on $\mathbb{R}^n$ Chapter9/Measure · hasTameSheetsIn_trivial_rn and every tame n-dimensional Θ for the n-dimensional sheets Chapter9/SheetMeasure · hasTameSheetsIn_of_isNDimensional. `Remark913Hyp`: `expNegInvGlue` Chapter9/Propositions · EpGroupoid.remark913Hyp_expNegInvGlue.

Hypotheses and readings that remain, with their witnesses. The class hypotheses (a) and (b) of the first forms of Theorems 9.5.15–9.5.18 are derived from the text's hypotheses (§§IX.36–IX.38); the forms with them are kept. (a) `hcov` (Theorems 9.5.15, 9.5.16): at every point of $\operatorname{supp}(\partial\Theta)$ an oriented tame structure describing $\widehat{T}_\Theta$ whose nonempty boundary sheets lie in the class of the integration; witnesses: $\Theta = 0$ `Chapter9/BoundaryMeasure · hcov_zero`, compact boundary sheets `Chapter9/BoundaryMeasure · hcov_msheets_of_isCompact`, and the closed upper hemisphere `Chapter9/HemisphereWitness · e8w_hcov` (§IX.34). (b) `hcovS` (Theorems 9.5.17, 9.5.18): at every point of $\operatorname{supp}(\Theta)$ such a structure whose sheets lie in one graph chart, for 9.5.18 with the local unique continuation property; witness: the closed upper hemisphere, $m = 1$ `Chapter9/HemisphereWitness · e8w_stokes_hypotheses` `Chapter9/HemisphereStokes · E8W.e8_hemisphere_stokes`, and for the LUC part the same hemisphere (§IX.38). Not derived from the text: (c) the bound on the dimensions of submanifolds for the local finiteness in Proposition 9.1.11 off the support; witness $\mathbb{R}^m$ `Chapter9/DimDecompositionExists · rn_hasDimAt_le` (§IX.4). Readings: (d) "oriented, tame" in §9.5 as `hloc`, near every point of the support an oriented tame structure describing $\widehat{T}_\Theta$; derived when $d_X = 0$ on the support `Chapter9/CoveringFromText · hloc_of_degIndex_eq_zero`, witnessed by the circle `Chapter9/CircleWitness · circle_witness` (§IX.32). (e) (9.22) for $\tau = f \cdot \omega$ read through the evaluation on frames, `IsMul`, witnessed by constants (§IX.33).

Unconditional. On every ep-groupoid: Propositions 9.1.11 (read among local decompositions, local finiteness on the support) and 9.1.12, Theorem 9.2.1, Lemma 9.2.7 (2), Lemma 9.3.4 for n-dimensional Θ, Lemma 9.4.3, Lemmas 9.4.4, 9.4.6 for n-dimensional Θ, Lemma 9.5.2 for n-dimensional Θ, Lemma 9.6.4, Proposition 9.6.5, Remark 9.1.4, Proposition 9.1.9; Definition 9.2.12 with $|X|$ paracompact; Theorems 9.5.4, 9.5.5 and 9.5.15–9.5.18 under the reading (d).

Witnesses for §9.5. The unit circle in $\mathbb{R}^2$, counter-clockwise: Theorems 9.5.4, 9.5.5 with compact nonempty support `Chapter9/FiniteTheoremText · circle_theorem_9_5_4_full`, the branched integral as the integral over S^1 `Chapter9/CircleOneSheet · circle_multiBranchedIntegral`, Proposition 9.5.13 (2) `Chapter9/ReducedCircle · circle_proposition_9_5_13_2`. The half-line $[0,\infty)$ with $\Theta = 1$: $\partial S = \{|0|\} \neq \emptyset$ and $L(\partial S)$ `Chapter9/BoundaryFaceNullSets · halfLine_lebesgueSigmaBoundary`. The closed upper hemisphere: Theorems 9.5.15–9.5.18 with $\partial S \neq \emptyset$ (§§IX.35, IX.36, IX.38). The closed half-circle in $[0,\infty) \times \mathbb{R}$: the same for $n = 1$ (§IX.38). The groupoid $\mathbb{Z}_3 \ltimes X$ of Remark 9.5.20 (§IX.39). The x-axis of $\mathbb{R}^2$: Remark 9.1.10 `Chapter9/XAxisWitness · remark_9_1_10_hypotheses_axis` and the one-chart class `Chapter9/TameOpen · hcov_axis`.

Counterexamples (each to a statement as we read it): the uniqueness in Proposition 9.1.11 `Chapter9/Propositions · EpGroupoid.not_proposition_9_1_11_rn`; the footnote to Definition 9.1.2 for $\Theta = 0$ `Chapter9/LocallyEquidimensional2021 · definition_9_1_2_footnote_zero`; Lemma 9.2.13 (2) ⇏ (1) off ∂X `Chapter9/BoundaryPosition · MPolyfold.not_lemma_9_2_13_two_one`; the uniqueness in Definition 9.2.16 `Chapter9/Boundary · not_unique_isBoundaryCharacterized_halfLine`; Lemma 9.3.4 without equidimensionality `Chapter9/OrientationRn · lemma_9_3_4_mixed_dim_rn`; "otherwise different" and "four possibilities" in Example 9.3.5 `Chapter9/OrientationExample · example_9_3_5_eq_of_neg` `Chapter9/OrientationExampleSigns · example_9_3_5_six` `Chapter9/OrientationExampleClasses · example_9_3_5_infinite`; Lemma 9.4.4 for sheets of different dimensions `Chapter9/BranchingGeometry · lemma_9_4_4_mixed_dim`; the transfer of null sets in Lemma 9.5.2 across dimensions `Chapter9/Measure · isNull_transfer_mixed_dim` `Chapter9/SheetMeasure · isHNull_mixed_dim`.

IX.24 What is not formalized

Gaps G.93–G.109 are closed, G.110 is formalized in part, for Remark 9.5.20 only, and no gap of the chapter is open.

- **G.110 (in part), Remark 9.5.20.** Formalized: the M-polyfold $X \subseteq \mathbb{R} \times \mathbb{C}$, $\partial X = \{(\pm 1, 0)\}$, $\mathbb{Z}_3 \ltimes X$ with the local unique continuation property, ∂X as a sub-ep-groupoid, and the effective isotropy at a point of ∂X, three read in X and one read in ∂X (§IX.39). Not formalized: $\Theta(t, z) = \delta_0(z)$ with its orientation, $\oint_{\hat{\Theta}} df = \frac{1}{3}(\phi(1) - \phi(-1))$ and the two boundary integrals, estimated at 2,340–3,790 lines; the main risks are sc-smooth partitions of unity on the c_0 scale of the example and the tameness of M at the infinite-dimensional ends. Theorems 9.5.17 and 9.5.18 themselves are proved as printed for every $n \geq 1$ (§§IX.36–IX.38).
- **Closed: G.109**, Theorems 9.5.15 and 9.5.16 as printed for every $n \geq 1$ (§§IX.36–IX.38), and with it the Theorems 9.5.17, 9.5.18 part of G.110.
- **Left inside closed gaps.** Local finiteness of the decomposition of Proposition 9.1.11 off the support without a bound on the dimensions (G.96). The form $f \cdot \omega$ for a non-constant sc-smooth f, read through the evaluation (G.107); in dimension 0 the integration is the abstract one `Chapter9/PointIntegration · pointIntegration`. The orientations of the faces of the faces, the last sentence of the caption of Figure 9.1 (G.103). The comparison of the face-by-face null sets with those taken in the ambient charts (G.108), and of the essential points in M-polyfold charts with those in corner charts (G.105), which no statement needs. A witness of Lemma 9.2.13 at a boundary point.
- **Nothing to formalize.** Remarks 9.3.1, 9.3.11 and 9.5.8 (the last has no content beyond Lemma 9.5.11); Remarks 9.5.12 and 9.5.19 and §§9.6.2–9.6.3 discuss open questions.

IX.25 What the formalization taught us

The definition of a branched ep⁺-subgroupoid is local and says nothing about how the local pictures fit together, and three statements that read as uniqueness claims, Proposition 9.1.11, Definition 9.2.16 and Lemma 9.3.4, turned out to depend on exactly that: an indicator can be split into a point and a punctured line, a characterization asked only on its own support is met by zero, and a lower-dimensional sheet through a bad point escapes the good points. In each case the repair is a condition that ties the object to the local branching structures of Θ (local decompositions, the largest support, equidimensionality). The analytic heart of §9.2, the graph representation of tangent sheets near a bad point, is a statement about one chart in which sheets of all dimensions are graphs; separated from the counting it serves, it became a single hypothesis, true on $\mathbb{R}^m$ by the inverse function theorem, from which Proposition 9.1.12, Theorem 9.2.1, Lemma 9.6.4 and Proposition 9.6.5 follow. Two steps the text leaves to "similarly" (Lemma 9.6.4) or asserts (the independence on p. 457) needed that both structures be compared on one common slice. Finally, "measure zero" in §9.6.1 is not needed: the arguments only use that a piece of a k-dimensional submanifold is not covered by finitely many thinner ones, which is topology. In §9.5 the opposite happens: the measure-theoretic part needs only that the null sets of the sheets form a local σ-ideal compatible on overlaps, and that compatibility is exactly where dimensions must agree; and of the isotropy computations that normalize the integrals, everything except the integrals themselves is finite group theory.

The second round of work taught more. *The level-0 hypotheses were one fact.* Every level-0 statement of §9.2 (the cone, the graphs, invariance of domain, the local constancy of rank, the level-1 continuity of frames) follows from one observation: the lift $1_0^1 \circ r$ of an sc⁺-retraction to level 1 is C^1 on the retract, so that Mathlib's inverse function theorem applies on level 1 and the conclusions descend through the inclusion. The project's first hypothesis, one cone for all submanifolds through a boundary point, was more than the text uses; one cone per tangent space is enough, and holds everywhere (§IX.27). *A tacit finiteness in §9.5.* The text integrates ω over measurable subsets of the sheets, which presupposes $\int |\omega| < \infty$.

For the sheets themselves this follows from compactness and the properness of $\operatorname{cl} U(x)$ (§IX.32); for the boundary sheets $\partial_1 M_i$ it was first an added hypothesis of Theorems 9.5.15–9.5.18 (§§IX.34–IX.35), and it follows from the continuity of Part I's chart forms up to the corners and, toward the frontier of $U(x)$, from a comparison of tangent spaces with other structures, in which $\{d = 1\}$ depends on the tangent space alone (§§IX.36–IX.37). The same proof needs facts the text does not state: that the sheets are Lindelöf, so that countably many neighbourhoods suffice in Theorems 9.5.4, 9.5.5; that $M_i \cap \operatorname{supp} \beta_k$ is compact in the proof of Stokes' theorem; that chart changes are differentiable along a finite-dimensional submanifold for the level-0 norms, which makes Definitions 9.4.1 and 9.4.5 chart independent; and, for Proposition 9.5.13 (2), a natural action of G_x^R built from that of G_x under the local unique continuation property. *Some hypotheses are not used.* Proposition 9.1.9 does not use the paracompactness of $|X|$, the continuity of $o_{\partial M}$ needs no tameness, only reduced codimension 1, and the effective clause of Lemma 9.5.11 needs no local unique continuation. *Examples are more rigid than they look.* In Example 9.3.5 every one-dimensional submanifold inside the support through the origin has tangent $\mathbb{R}(1,0)$ and meets every vertical line, and this rigidity determines all orientations: a three-parameter family, of which six have integer weights (§IX.29). *Paracompactness through metrizability.* In Remark 9.1.4 the step from a paracompact neighbourhood to a component compact set goes through metrizability, since a subspace of a paracompact space need not be paracompact (§IX.26).

Remark 9.5.20 needs infinite dimensions. In finite dimensions a finite group that fixes a boundary point and acts trivially on the face acts trivially on the inward normal as well, so the effective isotropy of a boundary point is the same read in X and in ∂X. The remark's example has to be an M-polyfold whose local dimension jumps at its boundary, $0 \to 3 \to 0$ (§IX.39).

IX.26 Remark 9.1.4, Proposition 9.1.9 (2017: 9.1) and Remark 9.1.10 (2017: 9.2)

Remark 9.1.4 (V9.63), new in the 2021 edition `Chapter9/OrbitSubsetMetrizable · EpGroupoid.remark_9_1_4`. *A paracompact $L \subseteq |X|$ is metrizable, and if $|\operatorname{supp}(\Theta)|$ is component compact, the paracompactness in Definition 9.1.2 (1) is automatic.* **The text's argument**, followed exactly. *Step 1.* $|X|$ is locally metrizable, regular and Hausdorff (Theorem 7.3.1), so a paracompact subspace is metrizable by Smirnov's theorem `Chapter9/OrbitSubsetMetrizable · EpGroupoid.remark_9_1_4_metrizable`. *Step 2.* A component compact K has an open paracompact neighbourhood U (Corollary 7.3.8), metrizable by Step 1 `Chapter9/OrbitSubsetMetrizable · EpGroupoid.remark_9_1_4_exists_nhds`. *Step 3,* which the text does not spell out: K is paracompact. A subspace of a paracompact space need not be paracompact, but a subspace of the metrizable U is metrizable, hence paracompact `Chapter9/OrbitSubsetMetrizable · EpGroupoid.metrizableSpace_of_isComponentCompact Chapter9/OrbitSubsetMetrizable · EpGroupoid.remark_9_1_4_paracompactSpace`. *Step 4.* So a functor with the other properties of Definition 9.1.2 and component compact $|\operatorname{supp}(\Theta)|$ is a branched ep⁺-subgroupoid `Chapter9/OrbitSubsetMetrizable · EpGroupoid.isBranchedEpSubgroupoid_of_isComponentCompact`, compact supports in particular `Chapter9/OrbitSubsetMetrizable · EpGroupoid.paracompactSpace_orbitSupp_of_isCompact`.

Proposition 9.1.9 (2) (V9.64), *for Θ of orbifold type, X induces a natural orbifold structure on $Z = |\operatorname{supp}(\Theta)|$.* **The text's proof.** Near $x \in \operatorname{supp}(\Theta)$ all sheets coincide, $\Theta = 1_{M_x}$; the groupoid with objects $\bigsqcup_x M_x$ and morphisms $\bigsqcup M(x,x')$ is étale and proper, the functor $\beta : M \to Z$ induces a homeomorphism $|\beta|$, and other choices give an equivalent structure. **The formalized proof.** *Step 1, one sheet.* Θ takes only the values 0 and 1, so a sheet missing a point of the support near x would make

$0 < \Theta < 1$ there; hence $\mathrm{supp}(\Theta) \cap U(x) = M_i$ for every i Chapter9/SupportOrbifold · EpGroupoid.supp_inter_eq_of_isOrbifoldType. *Step 2.* So $\mathrm{supp}(\Theta)$ is a smooth finite-dimensional submanifold of X Chapter9/SupportOrbifold · EpGroupoid.isSmoothSubmanifold_supp_of_isOrbifoldType, saturated, hence an ep-subgroupoid, whose full subcategory is an ep-groupoid (Proposition 7.1.22) Chapter9/SupportOrbifold · EpGroupoid.isEpSubgroupoid_supp_of_isOrbifoldType. *Step 3.* For a saturated A, the map $|A| \to \pi(A)$ induced by the inclusion is a homeomorphism Chapter9/SupportOrbifold · EpGroupoid.orbitSuppHomeomorph. This gives a choice-free form Chapter9/SupportOrbifold · EpGroupoid.proposition_9_1_9_two. *Step 4, the text's groupoid.* For a choice of local branching structures at all points of the support Chapter9/SupportGroupoidNaturality · SheetChoice, the sets $M_x = \mathrm{supp}(\Theta) \cap U(x)$ form an open cover Chapter9/SupportGroupoidNaturality · sheetCover, and the text's M is the refinement of Proposition 10.1.3 of the full ep-subgroupoid along it Chapter9/SupportGroupoidNaturality · textGroupoid: objects (x, y) with $y \in M_x$, morphisms $((x, x'), \varphi)$ with $s(\varphi) \in M_x$, $t(\varphi) \in M_{x'}$. It is an ep-groupoid, $|\beta|$ is a homeomorphism Chapter9/SupportGroupoidNaturality · textOrbitHomeomorph, and $M \to \mathrm{supp}(\Theta)$ is an equivalence over Z Chapter9/SupportGroupoidNaturality · proposition_9_1_9_two_text. *Step 5, independence.* A refinement of covers gives an equivalence of refinements Chapter9/SupportGroupoidNaturality · OpenCover.isEquivalence_refineFunctor; for two choices c, c' the common refinement by the $M_x \cap M'_{x'}$ gives $M_c \leftarrow M_{c,c'} \to M_{c'}$, a generalized isomorphism of Chapter 10 (Theorem 10.3.10) compatible with the homeomorphisms to Z Chapter9/SupportGroupoidNaturality · proposition_9_1_9_two_independent. "Equivalent orbifold structure" is read as this generalized isomorphism. The construction assumes $\mathrm{supp}(\Theta) \neq \emptyset$; for $\Theta = 0$ there is nothing to construct.

Proposition 9.1.9 (1), *for Θ of manifold type, a natural manifold structure on Z. Step 1.* Between two objects of the support there is at most one morphism, so the isotropy of the ep-subgroupoid is trivial Chapter9/SupportManifold · EpGroupoid.subsingleton_isotropy_of_isManifoldType, and π is injective on the domain of a natural representation Chapter9/SupportManifold · EpGroupoid.injOn_π_of_subsingleton_isotropy, the text's "Ψ_x is injective". *Step 2, descent.* A general lemma: a continuous, open, surjective, locally injective map p from an M-polyfold to a Hausdorff paracompact space, such that $p(a) = p(b)$ is realized near a by an sc-smooth f with $f(a) = b$ and $p \circ f = p$ Chapter9/DescentPolyfold · MPolyfold.IsDescentMap, pushes the charts forward Chapter9/DescentPolyfold · MPolyfold.descChart to compatible charts, an M-polyfold structure on the target Chapter9/DescentPolyfold · MPolyfold.descend for which p is a local sc-diffeomorphism Chapter9/DescentPolyfold · MPolyfold.isLocalScDiffeo_descend. *Step 3.* The orbit map $\mathrm{supp}(\Theta) \to Z$ is such a map, with $f = t \circ (s|U(\varphi))^{-1}$ Chapter9/SupportManifold · EpGroupoid.isDescentMap_orbitSupp, which gives the structure Chapter9/SupportManifold · EpGroupoid.proposition_9_1_9_one. *Step 4, "natural"* is read as uniqueness: any two M-polyfold structures on Z for which the orbit map is a local sc-diffeomorphism agree Chapter9/SupportGroupoidNaturality · EpGroupoid.proposition_9_1_9_one_unique. The paracompactness of $|X|$, a hypothesis of the proposition, is not used.

Remark 9.1.10 (V9.65, narrower). *For Θ n-dimensional with $d_{|X|} = 0$ on Z, the structures are classical. Step 1.* The support is an n-dimensional submanifold of degeneracy index 0 Chapter9/SupportClassicalStructures · EpGroupoid.isSubmanifoldOfDim_supp Chapter9/SupportClassicalStructures · EpGroupoid.degIndex_eq_zero_of_mem_supp, so it has a corner structure of dimension n (§IX.16), which a surjective local sc-diffeomorphism carries to Z Chapter9/SupportClassicalStructures · MPolyfold.HasCornerStructureOfDim.of_isLocalScDiffeo_surjective. *Step 2.* In case (1) Z is a Mathlib manifold, `IsManifold (□ n) ∞` Chapter9/SupportClassicalStructures · EpGroupoid.remark_9_1_10_manifold, and the orbit map is a Mathlib local diffeomorphism Chapter9/SupportGroupoidEtale · EpGroupoid.remark_9_1_10_manifold_proj. *Step 3.* In case (2), for every choice, the object and morphism spaces of M are Mathlib n-manifolds Chapter9/SupportClassicalStructures · EpGroupoid.remark_9_1_10_orbifold, and source, target, unit, inverse and the equiv-

alence to the support are Mathlib local diffeomorphisms Chapter9/SupportGroupoidEtale · EpGroupoid.remark_9_1_10_orbifold_etale, since a local sc-diffeomorphism between such corner structures of degeneracy index 0 is a Mathlib local diffeomorphism Chapter9/SupportGroupoidEtale · MPolyfold.isLocalDiffeomorph_of_isLocalScDiffeo. The row is narrower for two reasons: the dimension n is fixed, a Mathlib manifold having one model space while the text's Z may have components of different dimensions; and the composition of M is sc-smooth, as for every ep-groupoid, but not stated as Mathlib-smooth, Mathlib having no notion of an orbifold. Witness: the x-axis of $\mathbb{R}^2$ Chapter9/XAxisWitness · EpGroupoid.remark_9_1_10_hypotheses_axis.

IX.27 The level-0 facts on every M-polyfold: Remark 9.1.1 (2017: 9.1), Lemmas 9.2.9–9.2.11 (2017: 9.6–9.8), invariance of domain, and the level-1 continuity

These are the facts the first version of this part took as hypotheses (gaps G.93, G.97, G.98, G.100, all closed). **The text** works at level 0 in a chart, with $x = 0$ in a partial quadrant C and M the image of an sc⁺-retraction: $L = T_0M$ meets C in a set with interior in L (Lemma 9.2.9); M is a graph $a + B(a)$ over a cone in $L \cap C$ with $DB(0) = 0$ (Lemma 9.2.10), by inverting $\Phi(a) = a + PB(a)$ (Lemma 9.2.11); $\dim T_mM$ is locally constant (Remark 9.1.1); a point in the interior of the sets it meets is "clearly" good (Lemma 9.2.7 (2)). The text treats B as C^1 at level 0, while the retraction is only sc-smooth.

The level-1 calculus of an sc⁺-retraction. *Step 1.* For an sc⁺-retraction r the lift $1^1_0 \circ r$ into level 1 Chapter9/GeneralLevelZero · plusLift is C^1 on level 1 Chapter9/GeneralLevelZero · hasFDerivWithinAt_plusLift Chapter9/GeneralLevelZero · continuousOn_plusDeriv, strictly differentiable Chapter9/GeneralLevelZero · exists_strict_plusLift, and its derivative brought down by the inclusion ι is Dr Chapter9/GeneralLevelZero · toBase_plusDeriv. All estimates are proved on level 1 and brought down by ι; on the finite-dimensional $T = \operatorname{range} Dr(z)$ the two norms are equivalent. *Step 2, the chord estimate* ($DB(0) = 0$): chords of the retract are close to T Chapter9/GeneralLevelZero · exists_approx Chapter9/GeneralLevelZero · exists_strict_range. *Step 3, Lemma 9.2.9:* Dr maps into the cone of the quadrant Chapter9/GeneralLevelZero · nonneg_scDeriv, so a closed ball of T around an admissible direction h_1, scaled by small s, stays in C Chapter9/GeneralLevelZero · ScRetraction.exists_cone. *Step 4, Lemmas 9.2.10 and 9.2.11:* the projection of the retract onto T approximates the identity of T on small balls, so Mathlib's surjectivity theorem for maps approximating a linear map (`ApproximatesLinearOn`) inverts it over a cone, uniformly in the foot point Chapter9/GeneralLevelZero · exists_graph_unif Chapter9/GeneralLevelZero · exists_graph, and over a ball of T at interior points Chapter9/GeneralLevelZero · exists_graph_ball. *Step 5, invariance of domain:* if two sc⁺-retractions r_1, r_2 have the same tangent space at z, every point b of the first retract near z with $r_2(b)$ in the first retract is fixed by r_2. On level 1, with u the difference of the lifts of $r_2(b)$ and b, the chord estimate for both retractions gives $\|u\|_1 \le c\eta\|u\|_1$ with $c\eta < 1$, so $u = 0$ Chapter9/GeneralLevelZero · eq_of_range_eq. *Step 6, local constancy of the rank:* the idempotents $Dr(z)$, read on level 1, depend continuously on the point in the operator norm, and an idempotent at distance < 1 from another has rank at most that of the other Chapter9/GeneralLevelZero · finrank_range_le_of_norm_sub_lt; applied both ways, the rank is locally constant along the retract Chapter9/GeneralLevelZero · eventually_finrank_eq.

In an M-polyfold. *Step 7.* A submanifold A is, in a chart, the range of a chart sc⁺-retraction t Chapter9/GeneralLevelZero · exists_plusRetraction, whose derivative has range the chart tangent space Chapter9/GeneralLevelZero · chartTangent_eq_range, and on A the level-1 lift of the chart is $1^1_0 \circ t$ Chapter9/GeneralLevelZero · levelLift_eq_plusLift; so the dimension is the rank of Dt Chapter9/GeneralLevelZero · hasDimAt_finrank. *Step 8, consequences.* Remark 9.1.1 Chapter9/GeneralLevelZero · MPolyfold.

hasLocallyConstantDimAt (Step 6), invariance of domain Chapter9/GeneralLevelZero · hasDomainInvarianceAt (Step 5), the level-1 continuity along submanifolds Chapter9/GeneralLevelZero · hasContinuousLevelOneOn (Step 7). *Step 9, the graph representation.* Each tangent space T_xA has its admissible cone of directions Chapter9/GeneralLevelZero · goodDirections, and every submanifold through x is a graph over it Chapter9/GeneralLevelZero · isGraphChartAt_goodDirections. This is the class form `HasClassGraphChartAt`, one cone per tangent space, at every point Chapter9/GeneralLevelZero · hasClassGraphChartAt; at interior points one cone and the ball form serve all submanifolds Chapter9/GeneralLevelZero · exists_chart_mem_interior_of_degIndex_eq_zero Chapter9/GeneralLevelZero · isGraphBallAt_of_mem_interior Chapter9/GeneralLevelZero · hasGraphChartAt_of_mem_interior.

What follows Chapter9/GeneralCorollaries · exists_slice_of_classGraphChart. The slice arguments of §§IX.9–IX.10 and IX.21–IX.22 only use the cone of the class at hand, so they run with the class form: tangent slices at every point Chapter9/GeneralCorollaries · hasTangentSlicesAt, generic slices missing finitely many thinner sets Chapter9/GeneralCorollaries · exists_generic_slice_general, `TopMultiplicity` Chapter9/GeneralCorollaries · topMultiplicity, Proposition 9.1.12 Chapter9/GeneralCorollaries · proposition_9_1_12, Lemma 9.6.4 Chapter9/GeneralCorollaries · lemma_9_6_4_general, Proposition 9.6.5 Chapter9/GeneralCorollaries · proposition_9_6_5_general, the independence of Theorem 9.2.1 Chapter9/GeneralCorollaries · hasIndependentTangentSums, Lemma 9.2.7 (2) Chapter9/GeneralCorollaries · lemma_9_2_7_2_general, Proposition 9.1.11 in the reading of §IX.4 Chapter9/GeneralCorollaries · existsUnique_localDimDecomposition_general, and, with the boundary argument of §IX.15, Lemma 9.3.4 Chapter9/GeneralBoundaryPoints · lemma_9_3_4_general. Proposition 9.2.8 itself stays in slice form (V9.22).

IX.28 Lemmas 9.4.4 and 9.4.6 (2017: 9.13, 9.14) for the sheets of an M-polyfold, and Lemma 9.5.2 (2017: 9.16) with Lebesgue null sets

The sheets of an M-polyfold carry no manifold charts of their own, so Definitions 9.4.1 and 9.4.5 are read in the M-polyfold charts ψ of the ambient space, as the text itself does in the proof of Lemma 9.4.4 (gaps G.105, G.106, closed).

Definition 9.4.1 in M-polyfold charts. T_z^KM is the span of Mathlib's tangent cone of $\psi(K)$ at $\psi(z)$ in E_0 Chapter9/SheetEssentialChart2021 · chartRelTangent, and z is essential if it is a limit of points where $T^KM = TM$ in every chart Chapter9/SheetEssentialChart2021 · IsRelTangentFull Chapter9/SheetEssentialChart2021 · chartEssentialSet. *Step 1.* For $K \subseteq M$, $T_z^KM \subseteq T_zM$, since chords of the chart retract are approximated by its tangent space (§IX.27, Step 2) Chapter9/SheetEssentialChart2021 · chartRelTangent_le. *Step 2.* Conversely $T_zM \subseteq T_z^MM$: for level-1 directions p into the quadrant, $Dr(z)p$ is a limit direction of the retract, and these span the range of $Dr(z)$ since E_1 is dense in E_0 Chapter9/SheetEssentialChart2021 · ScRetraction.range_scDeriv_subset_span_tangentConeAt Chapter9/SheetEssentialChart2021 · chartTangent_subset_chartRelTangent. So every point of M is essential for $M \subseteq M$ and the reading is not degenerate Chapter9/SheetEssentialChart2021 · chartEssentialSet_self. *Step 3, chart independence.* On level 0 a chart change is only continuous, but along a finite-dimensional submanifold it is differentiable for the level-0 norms: the points of the chart image lie on level 1 with level-1 distance controlled by level-0 distance, because the chart retraction is sc^+ Chapter9/SheetChartChange · ScRetraction.exists_lift_lipschitz, and an sc^1 map is differentiable from level 1 to level 0 (Proposition 1.2.1) Chapter9/SheetChartChange · ScRetraction.hasFDerivWithinAt_of_isSc1 Chapter9/SheetChartChange · exists_hasFDerivWithinAt_transition. The derivative maps tangent cones to tangent cones Chapter9/SheetChartChange · exists_clm_tangentCone_chart_change, so "$T_z^KM = T_zM$" in one chart gives it in

all Chapter9/SheetChartChange · isRelTangentFull_of_chart.

Lemma 9.4.4 (V9.42, narrower) Chapter9/SheetEssentialChart2021 · lemma_9_4_4_chart. *For n-dimensional M, M', $K = M \cap M'$ has the same essential points in M and in M'.* The text's reduction to $T_0^D N$ is the pointwise statement, which holds in each chart separately: $T_z^K M = T_z M$ iff $T_z^K M' = T_z M'$, both tangent spaces being n-dimensional and containing T_z^K Chapter9/SheetEssentialChart2021 · isRelTangentFull_iff. At essential points $T_z M = T_z M'$, the note in Definition 9.4.7 Chapter9/SheetEssentialChart2021 · submanifoldTangent_eq_of_mem_chartEssentialSet. For different dimensions the lemma does not hold as we read it (§IX.17).

Definition 9.4.5 in M-polyfold charts. *Step 1.* `HNull d s`: the d-dimensional Hausdorff measure of s vanishes Chapter9/SheetNull · HNull. A subset C of a sheet has n-dimensional measure zero if its separable pieces have n-null chart images in every chart Chapter9/SheetNull · IsHNull; E_0 need not be separable, and a non-separable set has infinite Hausdorff measure, but the sheets are locally separable, so nothing is lost. It is a local σ-ideal Chapter9/SheetNull · isHNull_iUnion Chapter9/SheetNull · isHNull_of_local. *Step 2, why these are Lebesgue null sets.* Near a point of a sheet the tangent projection p onto $T_x M$ satisfies $\|(\psi a - \psi b) - p(\psi a - \psi b)\| \le \frac{1}{2}\|\psi a - \psi b\|$ Chapter9/SheetNull · exists_half_approx, so it is bi-Lipschitz there, and on $\mathbb{R}^n$ the n-dimensional Hausdorff measure is Lebesgue measure Chapter9/SheetNullBridge · hNull_iff_volume_euclidean. On a tame sheet these are exactly the null sets of Definition 9.4.5 in the smooth charts of the manifold with corners of §IX.16 Chapter9/SheetNullBridge · isHNull_iff_isMeasureZero_cornerChartedSpace Chapter9/SheetNullBridge · isHNull_iff_isMeasureZero_sheet. *Step 3, chart independence:* a map Lipschitz at each point sends separable null sets to null sets Chapter9/SheetChartChange · hNull_image_of_pointwise_lipschitz, which with Step 3 above gives Chapter9/SheetChartChange · isHNull_of_forall_exists_chart. *Step 4, positivity:* an n-dimensional sheet is not null in itself, its tangent projection containing a ball of $T_x M$ (§IX.27, the graph over a cone) Chapter9/SheetNull · not_isHNull_of_hasDimAt. *Step 5.* So the null sets form a `SheetNullSets` on the n-dimensional submanifolds with no hypothesis Chapter9/SheetNull · sheetNullSets; the transfer property is immediate, since the definition does not mention the sheet.

Lemma 9.4.6 (V9.44) Chapter9/SheetEssential · lemma_9_4_6_chart. *For $K \subseteq M$, M n-dimensional, $K \setminus K^e$ has measure zero.* The proof of §IX.17 transported through the tangent projection: every limit direction of $p(\psi(A))$ is the projection of a limit direction of $\psi(A)$, chords of M being close to the finite-dimensional tangent space Chapter9/SheetEssential · exists_mem_tangentConeAt_proj; the points of K where $T^K \neq T$ project to points of $p(\psi(K))$ where the tangent cone does not span, a Lebesgue null set by the density theorem Chapter9/SheetEssential · exists_hNull_chart_not_isRelTangentFull Chapter9/SheetEssential · isHNull_setOf_not_isRelTangentFull. The n-dimensional submanifolds carry the `SheetGeometry` and `SheetMeasureGeometry` of §§IX.17, IX.19 with no hypothesis Chapter9/SheetEssential · sheetGeometry Chapter9/SheetEssential · sheetMeasureGeometry.

For n-dimensional Θ, and Lemma 9.5.2 (V9.50, explicit). *Step 1.* Every local branching structure of an n-dimensional Θ has n-dimensional sheets Chapter9/SheetMeasure · isOfDim_of_isNDimensional: at a point of the support, a structure with n-dimensional sheets and any other structure have the same tangent sum (Theorem 9.2.1), so each sheet of the second has the tangent space of a sheet of the first. *Step 2.* So Lemmas 9.4.4 and 9.4.6 hold for the sheets of every structure of Θ Chapter9/SheetMeasure · lemma_9_4_4_of_isNDimensional Chapter9/SheetMeasure · lemma_9_4_6_of_isNDimensional, and Lemma 9.4.8, Propositions 9.4.9, 9.4.10 follow (§IX.17). *Step 3.* Definition 9.5.1 with these null sets Chapter9/SheetMeasure · IsMeasureZeroH, and Lemma 9.5.2 as printed: null preimages for some choice of structures iff for every structure Chapter9/SheetMeasure · lemma_9_5_2_of_isNDimensional, and for tame Θ iff for a choice of tame structures Chapter9/SheetMeasure · lemma_9_5_2_tame; the proof is that of §IX.19 with one class of sheets. *Step 4.* The

sets of measure zero form a σ-ideal Chapter9/SheetMeasure · isSigmaIdeal_isMeasureZeroH, S is not one of them Chapter9/SheetMeasure · not_isMeasureZeroH_orbitSupp, and $L(S)$ is the completion of §IX.19 Chapter9/SheetMeasure · remark_9_5_3_H Chapter9/SheetMeasure · lebesgueSigmaH_eq. Across dimensions the transfer does not hold as we read it Chapter9/SheetMeasure · isHNull_mixed_dim.

IX.29 Example 9.3.5 (2017: 9.1): all orientations of Θ

The text says that Θ has "four different possibilities to orient". With the first claim of §IX.15 settled, the question is what all orientations of Θ are (gap G.101, closed; V9.33, narrower). The support is $G^{++} \cup G^{--}$ Chapter9/OrientationExampleSheets · Ex935.supp_example935Theta, and $\operatorname{supp}(\Theta) \setminus \{0\}$ consists of four open arcs, G^{++} and G^{--} over $s > 0$ and over $s < 0$; $\Theta = 1$ on the arcs and $\Theta(0) = 2$ Chapter9/OrientationExampleSheets · Ex935.example935Theta_eq_one Chapter9/OrientationExampleSheets · Ex935.example935Theta_zero.

The sheets inside the support. Every sheet of a local branching structure of Θ lies in the support and is 1-dimensional (§IX.28). *Step 1, velocities.* A curve in the support through a point z of G_b has velocity in $\mathbb{R}(1, \beta_b'(z_0))$: off the origin it runs in G_b; at the origin $|\gamma_1| = \beta^{++}(\gamma_0)$ is $o(t)$ since β^{++} is flat, so the velocity is horizontal Chapter9/OrientationExampleSheets · Ex935.hasDerivAt_snd_eq_of_mem_Z. Hence every 1-dimensional submanifold inside the support has, at $z \in G_b$, the tangent space of G_b, and at the origin the tangent $\mathbb{R}(1, 0)$ Chapter9/OrientationExampleSheets · Ex935.submanifoldTangent_eq_of_subset_Z. *Step 2, signs.* Its orientation is one of $\pm(1, \beta')$ at every point Chapter9/OrientationExampleSheets · Ex935.tangent_eq_orTan_or, with a locally constant sign Chapter9/OrientationExampleSheets · Ex935.exists_isOpen_tangent_eq_orTan_iff. *Step 3, vertical lines.* A sheet through the origin meets every vertical line $\{s\} \times \mathbb{R}$ for small $|s|$, by the ball graph representation over $T_0M = \mathbb{R} \times 0$ Chapter9/OrientationExampleSheets · Ex935.exists_mem_fst_eq.

The classification Chapter9/OrientationExampleClasses · example_9_3_5_classification. *Step 1, normal form.* At a point y of the support an orientation is $c \cdot (1, \beta') + (\Theta(y) - c) \cdot (-(1, \beta'))$ Chapter9/OrientationExampleClasses · Ex935.eq_single_add_single. *Step 2, constancy along arcs.* Near a point of an arc every sheet of a structure is the arc with a locally constant sign (Step 2 above), so the coefficient a is constant along each arc, $0 \le a \le 1$ Chapter9/OrientationExampleClasses · Ex935.coef_pt_eq_of_pos Chapter9/OrientationExampleClasses · Ex935.coef_pt_eq_of_neg. *Step 3, the origin.* Every sheet of a structure at 0 meets each vertical line near 0 (Step 3 above), and the count $\Theta(s, \beta^{++}(s)) + \Theta(s, \beta^{--}(s)) = 2 = \Theta(0)$ forces it to meet it exactly once. With the constancy of the signs, the weight A of $(1, 0)$ at the origin is $a(+, G^{++}) + a(+, G^{--})$, and also $a(-, G^{++}) + a(-, G^{--})$ Chapter9/OrientationExampleClasses · Ex935.coef_zero_eq. *Step 4, the family.* So every orientation is a member of the family classOrient(a), a indexed by side and branch, with the two sums equal Chapter9/OrientationExampleClasses · Ex935.classOrient Chapter9/OrientationExampleClasses · Ex935.eq_classOrient, and different a give different orientations Chapter9/OrientationExampleClasses · Ex935.classOrient_injective. *Step 5, the converse.* Each member is an orientation: it is the oriented sum of the four graphs $G^{++}, G^{--}, G^{+-}, G^{-+}$, each with both orientations, with weights solving a 2×2 transport problem between the sides $s > 0$ and $s < 0$ Chapter9/OrientationExampleClasses · Ex935.exists_transport Chapter9/OrientationExampleClasses · Ex935.isOrientation_classOrient.

Consequences. Θ has infinitely many orientations, a three-parameter family Chapter9/OrientationExampleClasses · example_9_3_5_infinite; those with integer weights are exactly the six sign choices of §IX.15 Chapter9/OrientationExampleClasses · example_9_3_5_integral Chapter9/OrientationExampleClasses · example_9_3_5_integral_ncard. So "four different possibilities" holds for

each of the two structures, and for Θ it does not hold as we read it.

IX.30 The boundary operation, the continuity of $o_{\partial M}$, the stratum $\{d_M = 1\}$ and Figure 9.1 (Definitions 9.3.8 and 9.3.10 (2017: 9.9 and 9.11))

The text. For a tame M the points with $d_M(y) = 1$ form an open dense part of ∂M with a manifold structure; for (M, o) oriented, a basis $(a_1, \dots, a_{n-1})$ of $T_y\partial M$ is positive iff $(e, a_1, \dots, a_{n-1})$ is positive, e outward; these orientations "fit continuously together", and the orientation of the interior of a face extends to the closed face (Figure 9.1). §IX.16 formalized the linear algebra with $T_y\partial M$ and e as data. Here they are built from M (gap G.103, closed; V9.36–V9.38 explicit).

The boundary operation (`Chapter9/BoundaryOperation`). *Step 1, presented charts.* $T_y^R X$ and $C_y X$ are read in a chart with a presentation of its partial quadrant `Chapter9/BoundaryOperation · MPolyfold.PresentedChart`; a chart change acts on chart vectors over y by a continuous linear map carrying reduced space to reduced space and cone to cone `Chapter9/BoundaryOperation · MPolyfold.PresentedChart.exists_clm`, so "reduced", "inward" and the reduced codimension $\dim(L/L \cap T_y^R X)$ are chart independent `Chapter9/BoundaryOperation · MPolyfold.isReducedVec_iff` `Chapter9/BoundaryOperation · MPolyfold.isInwardVec_iff` `Chapter9/BoundaryOperation · MPolyfold.hasReducedCodim_iff`. *Step 2.* For tame M, $d_M(y)$ is the reduced codimension of T_yM, the content of Lemma 9.3.7's proof `Chapter9/BoundaryOperation · MPolyfold.subDegIndex_eq_quotDim_span`. *Step 3, the cone spans.* Every vector of T_yM is a difference of two vectors of $C_yM = T_yM \cap C_yX$ `Chapter9/BoundaryOperation · MPolyfold.exists_sub_eq_vec_submanifoldTangent`; so if T_yM has reduced codimension 1, C_yM is a half-space of T_yM bounded by $T_y^R M$ `Chapter9/BoundaryOperation · exists_coeff_halfSpace`, outward vectors exist `Chapter9/BoundaryOperation · MPolyfold.IsBoundaryAdmissible.exists_outward`, and two of them satisfy $e' = ce + k$ with $c > 0$, $k \in T_y^R M$ `Chapter9/BoundaryOperation · MPolyfold.IsBoundaryAdmissible.exists_pos`. *Step 4, the operation.* $T_y(M, o) \mapsto (T_y^R M, o_\partial)$, with the frames a such that (e, a) is positive for every outward e `Chapter9/BoundaryOperation · MPolyfold.boundaryOp`, a function of the oriented tangent set with no choice; by Step 3 and §IX.16 it is Definition 9.3.8 for any single outward e `Chapter9/BoundaryOperation · MPolyfold.boundaryOp_eq`. *Step 5, identification.* The chart image of its carrier is the reduced tangent space of the induced chart of M, $T_y\partial M = T_y^R M$ `Chapter9/BoundaryOperation · MPolyfold.chartVec_image_boundaryCarrier`, and "outward" means "not in the partial cone of M" `Chapter9/BoundaryOperation · MPolyfold.isOutward_iff_not_mem_partialCone`. *Step 6.* With it, $\hat{T}_{\partial\Theta}$ is the oriented sum filtered by reduced codimension 1, which needs no quantifier over submanifolds `Chapter9/BoundaryOperation · EpGroupoid.boundaryOrientation`; it agrees with Definition 9.3.10 for tame orientations `Chapter9/BoundaryOperation · EpGroupoid.boundaryLift_boundaryOp_eq_boundaryOrientation`, and Proposition 9.3.9 holds `Chapter9/BoundaryOperation · EpGroupoid.proposition_9_3_9_boundaryOrientation`. The situation occurs at the corner of $[0, \infty)$ `Chapter9/BoundaryOperation · MPolyfold.exists_isBoundaryAdmissible_halfLine`.

Continuity of $o_{\partial M}$ `Chapter9/BoundaryOrientationContinuity2021 · MPolyfold.SubmanifoldOrientation.exists_continuous_boundaryFrames`. The text says the orientations fit together "by definition". *Step 1.* The boundary stratum is the set of points where T_yA has reduced codimension 1 `Chapter9/BoundaryOrientationContinuity2021 · MPolyfold.boundaryStratum`, $\{d_A = 1\}$ for tame A `Chapter9/BoundaryOrientationContinuity2021 · MPolyfold.boundaryStratum_eq_of_tame`. *Step 2.* Let r be the chart sc⁺-retraction at y_0, w a positive frame of $o_{\partial A}$ at y_0, $s \in C_{y_0}A$ off $T_{y_0}\partial A$. For z in the stratum near y_0, $Dr(z)$ maps the partial quadrant and the reduced space at y_0 into those at z `Chapter9/BoundaryOrientationContinuity2021 · ScRetraction.scDeriv_mem_partialQuadrantAtWith` `Chapter9/`

BoundaryOrientationContinuity2021 · ScRetraction.scDeriv_mem_minimalSubspaceWith, so $Dr(z)w$ is a basis of $T_z\partial A$ by a dimension count, and $-Dr(z)s$ is outward. *Step 3.* The sign of $(-Dr(z)s, Dr(z)w)$ against a continuous positive frame of o is a frame determinant, locally constant (§IX.15). So $o_{\partial M}$ is an orientation along the stratum Chapter9/BoundaryOrientationContinuity2021 · MPolyfold.OrientationAlong Chapter9/BoundaryOrientationContinuity2021 · MPolyfold.SubmanifoldOrientation.boundaryOrientation, for every oriented submanifold: tameness is not used, only the reduced codimension 1. Every oriented structure gives one on each sheet Chapter9/BoundaryOrientationContinuity2021 · EpGroupoid.OrientedBranchingStructure.exists_boundaryOrientation.

The stratum. *Step 1, open and dense.* $\{d_Q = 1\} = \partial Q \cap \{d_Q \le 1\}$ is open in ∂Q for every M-polyfold Chapter9/BoundaryStratumDense · MPolyfold.setOf_degIndex_eq_one Chapter9/BoundaryStratumDense · MPolyfold.isOpen_degIndex_le_one, and dense in ∂Q for a corner structure, since in corner coordinates a point with vanishing coordinates is a limit of points with exactly one of them vanishing Chapter9/BoundaryStratumDense · MPolyfold.HasCornerStructureOfDim.boundary_subset_closure_degIndex_eq_one; so for a tame sheet the stratum is open and dense in ∂M Chapter9/BoundaryStratumDense · MPolyfold.exists_isOpen_boundaryStratum_eq Chapter9/BoundaryStratumDense · MPolyfold.submanifoldBoundary_subset_closure_boundaryStratum. *Step 2, a submanifold.* In corner coordinates κ, on the open piece where all coordinates but y_i are positive Chapter9/StratumRetraction · MPolyfold.CornerCoords.facePiece, the map $\kappa^{-1} \circ (y_i \mapsto 0) \circ \kappa$ is an sc-smooth retraction onto the points with $d = 1$ Chapter9/StratumRetraction · MPolyfold.CornerCoords.faceRet. With s the sc⁺-retraction of M, $\iota \circ \kappa^{-1} \circ (y_i \mapsto 0) \circ \kappa \circ s$ is an sc⁺-retraction of an open subset of X onto the stratum, the sc⁺ property coming from $r = s \circ r$ Chapter9/StratumRetraction · MPolyfold.exists_stratum_coords Chapter9/StratumRetraction · MPolyfold.exists_isScPlusRetractionOn_stratumOne Chapter9/StratumRetraction · MPolyfold.isSmoothSubmanifold_stratumOne Chapter9/StratumRetraction · MPolyfold.stratumOne_eq_boundaryStratum. *Step 3, dimension and tangent spaces.* In a chart the image of $T_y\partial_1 M$ is the image of the hyperplane $\{v_i = 0\}$ under the derivative of the inclusion Chapter9/StratumTangent · MPolyfold.chartTangent_stratumOne_eq, so $\partial_1 M$ is $(n-1)$-dimensional Chapter9/StratumTangent · MPolyfold.isSubmanifoldOfDim_stratumOne with $T_y\partial_1 M = T^R_y M$ Chapter9/StratumTangent · MPolyfold.submanifoldTangent_stratumOne. *Step 4, oriented.* $o_{\partial M}$ is an orientation of the submanifold $\partial_1 M$ in the sense of Definition 9.3.2's sheets Chapter9/BoundaryOrientation · MPolyfold.SubmanifoldOrientation.stratumOrientation Chapter9/BoundaryOrientation · MPolyfold.SubmanifoldOrientation.stratumOrientation_tangent. In corner coordinates where only y_i vanishes, $T\iota(v) \in C_y M$ iff $v_i \ge 0$ Chapter9/BoundaryOrientation · MPolyfold.isInwardVec_incFrame_iff, so $T\iota(-e_i)$ is outward, and a frame $T\iota(v_1), \dots, T\iota(v_m)$ of $\{v_i = 0\}$ is positive for $o_{\partial M}$ iff $(T\iota(-e_i), T\iota(v_1), \dots)$ is positive for o Chapter9/BoundaryOrientation · MPolyfold.incFrame_mem_boundaryFramesAt_iff: "outward normal first", Part I's rule for the faces of a manifold with corners.

Figure 9.1 Chapter9/FaceOrientation · MPolyfold.figure_9_1_existsUnique_faceOrientation. For a face-structured tame sheet, Part I reads the closed faces as manifolds with corners Chapter9/StokesFaceSum · MPolyfold.faceChartedSpace with the induced orientation, outward normal first Chapter9/StokesFaceSum · MPolyfold.faceOrientation. *Step 1, linear algebra.* $\det(-e_i, \iota_i v_1, \dots, \iota_i v_m) = (-1)^{i+1} \det v$ for the face embedding ι_i Chapter9/FaceOrientation · det_cons_neg_stdFrame_faceEmbedding, and the basis $(-e_i, \iota_i b)$ Chapter9/FaceOrientation · consFaceBasis has a given orientation iff b has the one Part I's rule assigns Chapter9/FaceOrientation · orientation_consFaceBasis_eq_iff. *Step 2, agreement.* At every point of a face with $d_M = 1$, a basis b of a face chart is positive for Part I's face orientation iff the frame $T\iota(\iota_i b_1), \dots, T\iota(\iota_i b_m)$ is positive for $o_{\partial M}$ Chapter9/FaceOrientation · MPolyfold.faceOrientation_eq_iff_mem_stratumOrientation Chapter9/FaceOrientation · MPolyfold.faceOrientation_eq_iff_mem_stratumOrientation_pair. *Step 3, extension.* The points with $d_M = 1$ are dense in each closed face Chapter9/FaceOrientation · MPolyfold.dense_faceStratum, and two continuous tangent orientations agreeing on a dense set are equal Chapter9/

`FaceOrientation · TangentOrientation.eq_of_eqOn_dense`. So the orientation of the open face extends to exactly one continuous orientation of the closed face, Part I's face orientation. The text's "interiors of the faces" are read as the points with $d_M = 1$, and "extends" as the unique continuous extension. The orientations of the faces of the faces (the caption's last sentence) are not formalized.

IX.31 Branched integration for an abstract sheet integration: (9.20), Lemma 9.5.7 (2017: 9.17), (9.21), Lemmas 9.5.9–9.5.11 (2017: 9.18, 9.19), Theorems 9.5.4, 9.5.5 (2017: 9.2, 9.3), Definition 9.5.6 and Proposition 9.5.13 (1)

The text. For an oriented local branching structure (M_i, o_i), (σ_i) on $U(x)$ with the natural G_x-action and a measurable $K \subseteq |M_U|$ with preimages $K_i \subseteq M_i$, the local measures are $\mu_\omega^U(K) = \frac{1}{\#G_x}\sum_i \sigma_i \int_{K_i} \omega|(M_i, o_i)$ and $\mu_\omega^{\mathrm{eff},U}$ with $\#G_x^{\mathrm{eff}}$ (9.21). They do not depend on the structure (Lemma 9.5.7, via (9.20)), on shrinking U (Lemmas 9.5.9, 9.5.10) or on moving along a morphism (Lemma 9.5.11); covering S by finitely many $|M_{U_p}|$ and summing gives a unique linear $\omega \mapsto \mu_\omega$ into the signed measures on $(S, L(S))$ with the local formula (Theorems 9.5.4, 9.5.5), and $\int_{\hat\Theta} \omega = \mu_\omega(S)$, $\oint_{\hat\Theta} \omega = \mu_\omega^{\mathrm{eff}}(S)$ (Definition 9.5.6). Rows V9.54–V9.57 and V9.66 are explicit or restated (gap G.107, closed).

The integration as a structure. *Step 1.* The measurable subsets of a sheet N are the sets whose trace differs from a Borel trace by a null set of N `Chapter9/SheetIntegrationAbstract · SheetNullSets.IsMeasIn`; two sheets induce the same measurable subsets of their intersection `Chapter9/SheetIntegrationAbstract · SheetNullSets.IsMeasIn.transfer`. *Step 2.* A `SheetIntegration` gives numbers $\int_A \omega|(N, o)$ for the forms ω of a real vector space Ω, the oriented sheets N of a class, and measurable $A \subseteq N$ `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration`, with the properties the text uses: linearity in ω, countable additivity, vanishing on null sets, equal (opposite) integrals over a common subset of two sheets where their oriented tangent spaces agree (are opposite), invariance under the sc-diffeomorphisms whose tangent maps are those of morphisms `Chapter9/SheetIntegrationAbstract · EpGroupoid.IsMorTangentOn`, Lindelöf sheets, and Lemma 9.4.6 with the note of Definition 9.4.7. It is built for sc-forms in §IX.32.

(9.20) and Lemma 9.5.7 `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration.sum_integ_eq_zero` `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration.sum_integ_eq_sum_integ`. *A finite family of oriented sheets with weights whose weighted sum of oriented tangent spaces vanishes at every point of K has $\sum_k w_k \int_{K\cap N_k} \omega|(N_k, o_k) = 0$.* **The text's proof** removes a null set and compares on the pieces of Proposition 9.4.10. **The formalized proof** redoes that decomposition for measurable pieces. *Step 1.* The points where two sheets through a point have different tangent spaces form a null set in every sheet `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration.isNull_tangentBad`. *Step 2.* The rest of K is cut into the finitely many measurable pieces on which the set of sheets through y and the pairs with equal oriented tangent space are constant `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration.piece` `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration.isMeasIn_piece` `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration.pairwise_disjoint_piece`. *Step 3.* On a piece all the integrals are $\pm$ the integral over one sheet, and the signed sum of the weights vanishes because a tangent space has two orientations `Chapter9/SheetIntegrationAbstract · EpGroupoid.SheetIntegration.sum_sign_weight_eq_zero`. The families need not pass through one point. For two oriented tame structures describing $\hat T_\Theta$ this gives Lemma 9.5.7 `Chapter9/LocalMeasure · lemma_9_5_7`.

(9.21) and Lemmas 9.5.9–9.5.11. *The local measures.* An oriented tame structure is a tame structure (natural representation, properness, tame sheets) with n-dimensional oriented sheets `Chapter9/LocalMeasure · OrientedTameStructure`; it describes $\hat{T}_\Theta$ if its oriented sum is $\hat{T}_\Theta$ near x `Chapter9/LocalMeasure · Represents`. The weighted sum $\sum_i \sigma_i \int_{A\cap M_i} \omega|(M_i, o_i)$ `Chapter9/LocalMeasure · sheetSum` divided by $\#G_x$ or $\#G_x^{\mathrm{eff}}$ is μ_ω^U, $\mu_\omega^{\mathrm{eff},U}$ `Chapter9/LocalMeasure · localMeasure` `Chapter9/LocalMeasure · localMeasureEff`, linear in ω and additive in the set `Chapter9/LocalMeasure · sheetSum_hasSum`. *Lemma 9.5.9* `Chapter9/LocalMeasure · lemma_9_5_9`: with the slice V of §IX.20 and the decomposition $M_U \cap \pi^{-1}(K) = \bigsqcup_{r\in R} \varphi_r(M_U \cap V \cap \pi^{-1}(K))$, each φ_r preserves the integrals, its tangent maps being those of morphisms `Chapter9/LocalMeasure · NaturalRep.isMorTangentOn_Φ` `Chapter9/LocalMeasure · sheetSum_image`, so the sum over U is $\#R$ times the sum over V `Chapter9/LocalMeasure · sheetSum_preimage_eq_card_mul_slice`; with $\#R \cdot \#G_y = \#G_x$ the normalized measures agree. The text takes the restricted structure on V; by Lemma 9.5.7 any structure at y describing $\hat{T}_\Theta$ serves, and the text's proof uses Lemma 9.5.7 and the naturality of $\hat{T}_\Theta$ here. *Lemma 9.5.10* `Chapter9/LocalMeasure · lemma_9_5_10`: the same with (9.23), $\#R \cdot \#G_y^{\mathrm{eff}} = \#G_x^{\mathrm{eff}}$ under the local unique continuation property. *Lemma 9.5.11* `Chapter9/LocalMeasure · lemma_9_5_11`: the local sc-diffeomorphism $\hat{\varphi} : U \to U'$ of a morphism has, at each point, the tangent map of a morphism, so it carries the structure on U to one on U' with the same sums `Chapter9/LocalMeasure · sheetSum_preimage_eq_of_morDiffeo`, and $\#G_x = \#G_{x'}$ (§IX.20). The effective clause holds without the local unique continuation property, only $\#G_x^{\mathrm{eff}} = \#G_{x'}^{\mathrm{eff}}$ being used. Remark 9.5.8 has no content beyond Lemma 9.5.11.

Theorems 9.5.4 and 9.5.5 `Chapter9/BranchedIntegral · theorem_9_5_4` `Chapter9/BranchedIntegral · theorem_9_5_5`. *Step 1, measurability.* The local sc-diffeomorphism $t \circ (s|U(\varphi))^{-1}$ of a morphism has the tangent maps of the morphisms of its sheet `Chapter9/BranchedIntegral · isMorTangentOn_hat`, and the preimage of $K \in L(S)$ has measurable traces on the sheets, by Lemma 9.5.2 `Chapter9/BranchedIntegral · OrientedTameStructure.isMeas_preimage`. *Step 2, overlaps.* Near two points $z \in U$, $z' \in U'$ over one point of $|X|$ the two local measures agree, combining Lemmas 9.5.9 and 9.5.11 `Chapter9/BranchedIntegral · exists_slice_pair` `Chapter9/BranchedIntegral · exists_local_agreement`; since the sheets are Lindelöf, countably many such neighbourhoods cover a measurable $K \subseteq |M_U| \cap |M_{U'}|$, and the two structures give the same measure of K `Chapter9/BranchedIntegral · overlap`. The text does not mention that countably many pieces suffice. *Step 3, gluing.* Each structure gives a signed measure on $(S, L(S))$, linear in ω `Chapter9/BranchedIntegral · localSignedMeasure`. On a compact space with a σ-algebra containing the Borel sets, linear local expressions on the members of an open cover that agree on overlaps glue to exactly one linear map into signed measures: cut K into the pieces $W_k \setminus \bigcup_{j<k} W_j$ of a finite subcover and add `Chapter9/MeasureGlue · existsUnique_linearMap_signedMeasure_of_local` `Chapter9/MeasureGlue · existsUnique_linearMap_signedMeasure_of_openCover`. This is the text's "defines our desired signed measure". *Step 4.* Hence exactly one linear $\omega \mapsto \mu_\omega$ with the local formula for every oriented tame structure with sheets in the class describing $\hat{T}_\Theta$ and every measurable $K \subseteq |U(x)|$ `Chapter9/BranchedIntegral · existsUnique_branchedMeasure` `Chapter9/BranchedIntegral · branchedMeasure` `Chapter9/BranchedIntegral · branchedMeasureEff`, given such a structure at every point of the support (`hcov` in this abstract form, the class condition of the integration). *Definition 9.5.6* `Chapter9/BranchedIntegral · branchedIntegral` `Chapter9/BranchedIntegral · branchedIntegralEff`, and the identity after Theorem 9.5.5, $\mu^{\mathrm{eff},U} = (\#G_x/\#G_x^{\mathrm{eff}})\,\mu^U$ `Chapter9/BranchedIntegral · OrientedTameStructure.localMeasureEff_eq`. *Proposition 9.5.13 (1)*: for effective X the two integrals agree `Chapter9/BranchedIntegral · proposition_9_5_13_1`. A witness in dimension 0: points as sheets, the integral the signed value of an invariant function `Chapter9/PointIntegration · pointIntegration`.

IX.32 The integral of sc-differential forms over oriented sheets, and Theorems 9.5.4 and 9.5.5 as printed

The text integrates "$\omega|(M_i, o_i)$" over measurable subsets of the sheets without constructing the integral; the sheets are manifolds with boundary and corners and ω an sc-differential form on the ep-groupoid (Definition 8.2.1). Here the integral is built for $n \geq 1$ and shown to be a `SheetIntegration` of §IX.31, first on sheets in one chart, then on sheets covered by countably many charts (gap G.107, closed).

Evaluating forms. *Step 1.* An evaluation of forms is a real vector space Ω with values $\omega(\alpha_1, \dots, \alpha_n)$ on tangent vectors, linear in ω, alternating and multilinear on the tangent space of a submanifold (stated through determinants), invariant under the tangent maps of morphisms, and continuous along continuous frame fields `Chapter9/GraphChart · FormEval`. *Step 2.* The forms $\Omega^n_{ep}(X)$ of Definition 8.2.1 are one: the chart expression of ω is sc-smooth, hence continuous along level-1 lifts, which are continuous along a submanifold since the chart retraction is sc^+ `Chapter9/FormEvalEp · MPolyfold.continuousWithinAt_levelLift` `Chapter9/FormEvalEp · epFormEval`. *Step 3.* The direct limit $\Omega^n_{ep,\infty}(X)$ of Definition 8.2.2 is one too: a submanifold of X in X_∞ is one of every level X^i with the same tangent spaces and continuous frame fields, so the forms of X^i are evaluated on lifted tangent vectors, compatibly with the steps of the limit `Chapter9/FormEvalInfty · IsSmoothSubmanifold.levelOne` `Chapter9/FormEvalInfty · epFormsInftyEval`.

Graph charts. *Step 1.* A graph chart of an n-dimensional submanifold N is a chart φ of the M-polyfold containing N and a continuous linear $p : E_0 \to \mathbb{R}^n$, injective on $\varphi(N)$, whose inverse is differentiable within $p(\varphi(N))$ with derivative a linear isomorphism onto the chart image of T_yN, continuous in y `Chapter9/GraphChart · MPolyfold.GraphChart`. No corner structure of N is used, and derivatives are taken within a set that need not be open. *Step 2.* Near every point of an n-dimensional submanifold there is one: the tangent projection of §IX.28 is bi-Lipschitz on N near the point, and its image is closed `Chapter9/GraphChartExists · ScRetraction.exists_graphData` `Chapter9/GraphChartExists · exists_graphChart`. *Step 3, the integral in a chart.* The density is $\pm\omega(\partial_1, \dots, \partial_n)$ for the coordinate frame, with sign $+$ where the frame is positive for the orientation `Chapter9/ChartIntegral · density`, and $\int_A$ is its Lebesgue integral over the coordinate image of $A \cap N$ `Chapter9/ChartIntegral · chartInteg`; the sign is locally constant on N `Chapter9/FrameSign · GraphChart.exists_isOpen_isPos`. *Step 4, the comparison of two charts.* At a common point of two sheets with $T_yN = T_yN'$ the coordinate change is differentiable within the coordinate image of $N \cap N'$, with derivative expressing one frame in the other `Chapter9/GraphChartTransition · GraphChart.exists_transition`; the change of variables for maps differentiable on a measurable set `Chapter9/GraphChart · integral_image_eq_of_det` `Chapter9/GraphChartTransition · GraphChart.setIntegral_coord_image_eq` gives equal integrals where the oriented tangent spaces agree and opposite ones where they are opposite `Chapter9/ChartIntegral · FormEval.chartInteg_congr` `Chapter9/ChartIntegral · FormEval.chartInteg_neg`. With $N = N'$ this is the independence of the graph chart; no smoothness of $N \cap N'$ is needed. This is how the proof of Lemma 9.5.7 compares sheets. *Step 5.* Invariance under the sc-diffeomorphisms whose tangent maps are those of morphisms `Chapter9/ChartIntegral · FormEval.chartInteg_mapDiffeo`.

The one-chart integration `Chapter9/SheetIntegrationConcrete · FormEval.sheetIntegration`. The class consists of the n-dimensional submanifolds in one graph chart on which every form is absolutely integrable `Chapter9/SheetIntegrationConcrete · FormEval.sheets`, the null sets are the n-dimensional Hausdorff null sets `Chapter9/SheetIntegrationConcrete · FormEval.sheetNull`, and the integral is that of Step 3 `Chapter9/SheetIntegrationConcrete · FormEval.integ`; all fields of a `SheetIntegration` hold, among them the Lindelöf property, through the coordinate homeomorphism `Chapter9/SheetIntegrationConcrete · FormEval.`

hereditarilyLindelofSpace, and the integral vanishes where ω vanishes on the sheet Chapter9/SheetIntegrationConcrete · FormEval.integ_eq_zero_of_ev_eq_zero. With it, §IX.31 gives Theorems 9.5.4, 9.5.5 for structures whose sheets lie in one graph chart Chapter9/TameOpen · theorem_9_5_4_tame Chapter9/TameOpen · theorem_9_5_5_tame Chapter9/TameOpen · tameBranchedIntegral; such structures exist near every point of the support once some oriented tame structure does, by restriction to a smaller domain Chapter9/IntegralCovering · exists_restrict_mem_sheets Chapter9/TameOpen · HasTameInducedStructure.inter_isOpen Chapter9/TameOpen · hcov_of_loc.

Several charts. *Step 1, $\int|\omega|$.* In a graph chart, $\int_A|\omega|$ bounds $|\int_A\omega|$, does not depend on the chart, is invariant under morphisms and countably additive Chapter9/ChartAbsIntegral · abs_chartInteg_le Chapter9/ChartAbsIntegral · chartAbs_congr Chapter9/ChartAbsIntegral · chartAbs_mapDiffeo. *Step 2.* A sheet covered by countably many open V_k with $N\cap V_k$ in the one-chart class has the disjoint Borel pieces $P_k = N\cap V_k\setminus\bigcup_{j<k}V_j$ Chapter9/MultiChart · ChartCover; the cover is finite in the sense $\sum_k\int_{P_k}|\omega| < \infty$ Chapter9/MultiChart · ChartCover.IsFinite, and then $\int_A\omega = \sum_k\int_{A\cap P_k}\omega$ converges absolutely Chapter9/MultiChart · ChartCover.gInteg. *Step 3, independence.* Two covers, or two sheets over a common set where their oriented tangent spaces agree or are opposite, give equal or opposite sums, by a double series over the pieces of the two covers Chapter9/MultiChart · hasSum_of_double Chapter9/MultiChart · ChartCover.gInteg_eq_of. *Step 4.* The class of sheets with a finite cover Chapter9/MultiChart · FormEval.msheets carries a `SheetIntegration` Chapter9/MultiChartIntegration · FormEval.msInteg Chapter9/MultiChartIntegration · FormEval.msheetIntegration that contains the one-chart class and agrees with it there Chapter9/MultiChartIntegration · FormEval.sheets_subset_msheets Chapter9/MultiChartIntegration · FormEval.msInteg_eq_integ; Theorems 9.5.4, 9.5.5 follow for structures with sheets in this class Chapter9/MultiChartTheorem · theorem_9_5_4_multi Chapter9/MultiChartTheorem · theorem_9_5_5_multi Chapter9/MultiChartTheorem · multiBranchedIntegral Chapter9/MultiChartTheorem · multiBranchedIntegralEff. Compact sheets are in it Chapter9/MultiChartCompact · msheets_of_isCompact.

The finiteness the text uses tacitly Chapter9/FiniteTheorem · msheets_of_orientedTameStructure. The text integrates over measurable subsets of the sheets, which presupposes $\int|\omega|<\infty$. For the sheets of an oriented tame structure of a compact n-dimensional Θ it holds. *Step 1.* The support is locally compact, being locally a finite union of finite-dimensional submanifolds; a compact $K'\subseteq\operatorname{supp}(\Theta)$ meets every orbit of the support since $|\operatorname{supp}(\Theta)|$ is compact; and $\operatorname{supp}(\Theta)\cap U\subseteq s(\{\varphi\mid s(\varphi)\in\operatorname{cl}U,\ t(\varphi)\in K'\})$, compact by the properness of $\operatorname{cl}U$ (Definition 7.5.8) Chapter9/FiniteTheorem · exists_isCompact_supp_inter. *Step 2.* An n-dimensional submanifold inside a compact part of the support is covered by finitely many one-chart sheets of structures at points of it Chapter9/FiniteTheorem · msheets_of_subset_isCompact, and $\int|\omega|$ over it is dominated by the finitely many one-chart integrals Chapter9/FiniteDominated · chartAbs_eq_of_borel Chapter9/FiniteDominated · isFinite_of_dominated. *Step 3, Theorems 9.5.4 and 9.5.5 as printed* Chapter9/FiniteTheorem · theorem_9_5_4_full Chapter9/FiniteTheorem · theorem_9_5_5_full: there is exactly one linear $\omega\mapsto\mu_\omega$ into the signed measures on $(S,L(S))$ with $\mu_\omega(K)=\mu_\omega^U(K)$ for every oriented tame structure describing $\hat T_\Theta$ and every measurable $K\subseteq|U(x)|$; the n-dimensionality of Θ follows from the hypothesis Chapter9/FiniteTheorem · isNDimensional_of_loc.

The reading `hloc` of "oriented, tame". The theorems take as hypothesis that every point of the support has an oriented tame structure describing $\hat T_\Theta$. Without boundary it follows from the text's hypotheses Chapter9/CoveringFromText · hloc_of_degIndex_eq_zero: the oriented structure of Definition 9.3.2 has n-dimensional sheets, and restricted to the domain of a natural representation inside an open set with the properness property it is tame, every submanifold having a tame induced structure when $d_X = 0$ Chapter9/CoveringFromText · exists_orientedTameStructure_of_degIndex_eq_zero Chapter9/

FiniteTheoremText · theorem_9_5_4_full_of_degIndex_eq_zero. With boundary, Definition 9.3.6 gives tame sheets of *some* structure and Definition 9.3.2 oriented sheets of *another*; that the oriented structure can be taken tame is the reading of "tame".

Part I's integral, and a witness. Over a tame sheet the integral equals Part I's manifold integral of the restricted form for the corresponding tangent orientation Chapter9/ManifoldBridge · bridgeOrientation Chapter9/ManifoldBridge · isContinuous_bridgeOrientation Chapter9/ManifoldIntegralBridge · FormEval.integ_eq_manifoldIntegral, chart by chart of a partition of unity by the change of variables between graph and corner coordinates Chapter9/ManifoldBridge · FormEval.chartInteg_eq_setIntegral_corner; for classes of $\Omega^n_{ep,\infty}(X)$ represented on any level see Chapter9/LevelRestrict · epFormsInftyEval_integ_eq_integral. The unit circle in $\mathbb{R}^2$, the image of the radial retraction $r \mapsto r/|r|$ of $\mathbb{R}^2 \setminus \{0\}$, oriented counter-clockwise Chapter9/CircleWitness · rnPolyfold_isSubmanifoldOfDim_unitCircle2 Chapter9/CircleWitness · circleOrientation, satisfies all hypotheses with compact nonempty support Chapter9/CircleWitness · circle_witness Chapter9/FiniteTheoremText · circle_theorem_9_5_4_full, and with $U(x) = \mathbb{R}^2$ and the whole circle as one sheet $\int_{\hat\Theta} \omega = \int_{S^1} \omega$ Chapter9/CircleOneSheet · circle_multiBranchedIntegral.

IX.33 (9.22) and Proposition 9.5.13 (2)

(9.22) (V9.69, explicit). *If $\tau = f \cdot \omega$, then $d\mu_\tau = \bar f \, d\mu_\omega$, with $\bar f \circ \pi = f$.* **Reading.** $f \cdot \omega$ is read through the evaluation, $\tau(\alpha) = f(y)\,\omega(\alpha)$ on the frames of the tangent spaces T_yN of the sheets Chapter9/DensityLocal · IsMul, witnessed for constant f Chapter9/DensityLocal · isMul_smul; the form $f \cdot \omega$ for a non-constant sc-smooth f is not built. *Step 1, local, exact.* In a graph chart, $\int_A \tau$ is the integral of f times the density of ω Chapter9/DensityLocal · integ_eq_setIntegral_mul, so $\mu^U_\tau(K)$ is (9.21) for ω with f inserted in the integrands Chapter9/DensityLocal · OrientedTameStructure.localMeasure_eq_sum_setIntegral_mul. *Step 2, the estimate.* If $|\bar f - a| \le \varepsilon$ on K, then $|\mu_\tau(K) - a\,\mu_\omega(K)| \le \varepsilon\, M_\omega(K)$ with $M_\omega(K) = \frac{1}{\#G_x} \sum \sigma_i \int_{K_i} |\omega|$, additive in K Chapter9/DensityLocal · OrientedTameStructure.abs_localMeasure_sub_le Chapter9/DensityLocal · abs_branchedMeasure_sub_le Chapter9/DensitySignedMeasure · OrientedTameStructure.absSheetSum_union. *Step 3, integrals against a signed measure.* Mathlib's integral against a vector measure is, for a signed measure s, $\int_K g\, ds^+ - \int_K g\, ds^-$ for the Jordan decomposition Chapter9/SignedMeasureIntegrals · SignedDensity.setIntegral_eq_jordan. If a second signed measure t satisfies the estimate of Step 2 against s on the measurable subsets of a set, then $t(K) = \int_K g\, ds$, by Riemann–Stieltjes sums over the partition of K by the values of g and $\varepsilon \to 0$ Chapter9/SignedMeasureIntegrals · SignedDensity.eq_setIntegral_of_estimate; on a compact space, estimates near every point suffice Chapter9/SignedMeasureIntegrals · SignedDensity.eq_setIntegral_of_local_estimate. *Step 4.* So for $\bar f$ bounded and $L(S)$-measurable, continuous for instance, $\mu_\tau(K) = \int_K \bar f \, d\mu_\omega$ for every $K \in L(S)$, and the same for the effective measures Chapter9/DensitySignedMeasure · eq_setIntegral_of_sheetSum Chapter9/DensitySignedMeasure · branchedMeasure_eq_setIntegral_mul Chapter9/DensitySignedMeasure · branchedMeasureEff_eq_setIntegral_mul Chapter9/DensitySignedMeasure · branchedMeasure_eq_jordan.

Proposition 9.5.13 (2) (V9.57, restated). *Under the local unique continuation property, $\oint_{\hat\Theta} \omega = \int_{\hat\Theta'} \omega'$ on the reduced ep-groupoid X_R.* **The text's proof**: X and X_R have the same object M-polyfold, $\Theta' = \Theta$, "we can take the same local branching structure", and $\#G^{\mathrm{eff}}_x = \#G'_x$. **The formalized proof.** *Step 1, the natural action of G^R_x*, which "the same local branching structure" needs and the text does not construct. For a natural representation of G_x on $U(x)$ with the property of Definition 7.2.18, $\Phi^R([g]) = \Phi(g)$ and $\Gamma^R([g], y) = [\Gamma(g, y)]$ define one of $G^R_x = G_x/T_x$ on the same $U(x)$ Chapter9/ReducedRep · NaturalRep.toReduced: Φ descends because $T_x = \ker \Phi$ Chapter9/ReducedRep · Φ_eq_of_reducedIsotropyHom_eq, Γ be-

cause $\Gamma(gk,y) = \Gamma(g,y)\circ\Gamma(k,y)$ with $\Gamma(k,y)$ trivial in X_R Chapter9/ReducedRep · reducedπ_Γ_eq_of_reducedIsotropyHom_eq, and the uniqueness in Theorem 7.1.13 (3) holds because $[\Gamma(a,y)] = [\Gamma(b,y)]$ forces $a = bc$ with $\Phi(c) = \mathrm{id}$ near y, and the local unique continuation property gives $c \in T_x$ Chapter9/ReducedRep · reducedIsotropyHom_eq_of_reducedπ_Γ_eq. *Step 2, the same structures.* The properness property, tame and oriented tame structures carry over with the same U, sheets, weights and orientations Chapter9/ReducedRep · HasPropernessProperty.toReduced Chapter9/ReducedRep · OrientedTameStructure.toReduced, and $\#G_x^R = \#G_x^{\mathrm{eff}}$ Chapter9/ReducedRep · card_isotropy_reduced_eq_card_effIsotropy. *Step 3, the same integrals.* The tangent map of $[\varphi]$ is that of φ Chapter9/ReducedRep · tangentMor_reducedπ, so a form of X is one of X_R and a sheet integration on X is one on X_R with the same integrals Chapter9/ReducedRep · SheetIntegration.toReduced; the orientation carries over Chapter9/ReducedRep · IsOrientation.toReduced. *Step 4, the same σ-algebra.* $|X| \cong |X_R|$ and $|\mathrm{supp}(\Theta)|$ in both are identified Chapter9/ReducedIntegral · orbitHomeomorphReduced Chapter9/ReducedIntegral · orbitSuppHomeomorphReduced, carrying $L(S)$ to $L(S)$ Chapter9/ReducedIntegral · measurableSet_image_orbitSuppHomeomorphReduced. *Step 5.* By the uniqueness in Theorem 9.5.4 on X_R, $\mu^{\mathrm{eff}}_{\hat\Theta,\omega}(K) = \mu_{\hat\Theta',\omega'}(K)$ for $K \in L(S)$ Chapter9/ReducedIntegral · proposition_9_5_13_2_measure, and with $K = S$ the proposition Chapter9/ReducedIntegral · proposition_9_5_13_2. The local unique continuation property also makes the morphism space of X_R Hausdorff, so that X_R is an ep-groupoid. No hypothesis is added. Witness: the circle Chapter9/ReducedCircle · circle_proposition_9_5_13_2.

IX.34 Definition 9.5.14 (2017: 9.17) with $(n-1)$-dimensional null sets, and Theorems 9.5.15, 9.5.16 (2017: 9.4, 9.5): the boundary measures

The text. For $K \subseteq |\partial M_U|$ the preimages lie in the ∂M_i, manifolds with boundary and corners, and measure zero is $(n-1)$-dimensional Lebesgue measure zero in every boundary face (p. 448). Then (Theorem 9.5.15) there is a linear map $\omega \mapsto \mu^\partial_\omega$ into the signed measures on $(\partial S, L(\partial S))$, "uniquely characterized" by $\mu^\partial_\omega(K) = \frac{1}{\#G_x}\sum_i \sigma_i \int_{K_i} \omega|(\partial M_i, o_{\partial M_i})$, and Theorem 9.5.16 the same with $\#G_x^{\mathrm{eff}}$ under the local unique continuation property; the proof is "using the same techniques" as Theorem 9.5.4.

The null sets of the boundaries (gap G.108, closed; V9.52, V9.53). *Step 1.* As for the sheets (§IX.28), $(n-1)$-dimensional measure zero is read in the M-polyfold charts with the $(n-1)$-dimensional Hausdorff measure. *Step 2, positivity.* In corner coordinates of dimension $m+1$, near a point whose only vanishing coordinate is y_i, the chart image of $\{y_i = 0\}$ is an open piece of a coordinate hyperplane, not m-null Chapter9/BoundaryNotNull · MPolyfold.CornerCoords.not_hNull_chart_coord_eq_zero; so a nonempty ∂M of a tame n-dimensional sheet is not $(n-1)$-null Chapter9/BoundaryNotNull · MPolyfold.HasCornerStructureOfDim.not_isHNull_boundary Chapter9/BoundaryNotNull · MPolyfold.not_isHNull_submanifoldBoundary. *Step 3.* These null sets form a null-set system on the class of the boundaries of tame sheets with no hypothesis Chapter9/BoundaryNullSigmaAlgebra · MPolyfold.tameBoundaries Chapter9/BoundaryNullSigmaAlgebra · MPolyfold.boundaryNullSets; for $n = 1$ they are the counting null sets Chapter9/BoundaryNullSigmaAlgebra · MPolyfold.boundaryNullSets_one_isNull_iff Chapter9/BoundaryFaceNullSets · SheetNullSets.point. *Step 4, well defined.* For n-dimensional Θ, K has measure zero in ∂S iff near each point of $\mathrm{supp}(\partial\Theta)$ a tame structure has $\partial M_i \cap \pi^{-1}(K)$ null for all i, and then every tame structure has Chapter9/BoundaryNullSigmaAlgebra · EpGroupoid.isMeasureZeroBoundary_boundaryNullSets_iff Chapter9/BoundaryNullSigmaAlgebra · EpGroupoid.isHNull_boundary_of_isMeasureZeroBoundary; Definition 9.5.14 is Chapter9/BoundaryNullSigmaAlgebra · EpGroupoid.lebesgueSigmaBoundaryH. *Step 5, the corners.* A codimension-2 coordinate subspace of $\mathbb{R}^n$ is $(n-1)$-null, so the points with $d_M \geq 2$ are $(n-1)$-null Chapter9/

BoundaryNullSigmaAlgebra · MPolyfold.isHNull_two_le_subDegIndex and ∂M minus the stratum $\{d_M = 1\}$ is null Chapter9/BoundaryNullSigmaAlgebra · MPolyfold.isHNull_submanifoldBoundary_diff_boundaryStratum: the boundary integral lives on the stratum. *Face by face.* The text's notion for a face-structured sheet is formalized as a proper σ-ideal Chapter9/BoundaryFaceNullSets · MPolyfold.IsFaceNull Chapter9/BoundaryFaceNullSets · MPolyfold.not_isFaceNull_face; its comparison with the ambient reading is not formalized, and no statement needs it. *Witness with $\partial S \neq \emptyset$:* $\Theta = 1$ on $[0, \infty)$, tame and 1-dimensional Chapter9/BoundaryFaceNullSets · halfLineTame, with $|0| \in \partial S$ Chapter9/BoundaryFaceNullSets · halfLine_orbitSupp_boundary_nonempty and $L(\partial S)$ the Borel sets Chapter9/BoundaryFaceNullSets · halfLine_lebesgueSigmaBoundary.

The boundary sheets. *Step 1.* For an oriented tame structure of dimension $m + 1$, $\partial_1 M_i = \{d_{M_i} = 1\}$ is an m-dimensional submanifold (§IX.30) with the orientation $o_{\partial M_i}$ Chapter9/BoundarySheets · OrientedTameStructure.boundarySheet Chapter9/BoundarySheets · OrientedTameStructure.boundaryOrient. *Step 2, (9.12) with the stratum.* If the structure describes $\hat{T}_\Theta$, then $\hat{T}_{\partial\Theta}(y) = \sum_{y \in \partial_1 M_i} \sigma_i T_y(\partial_1 M_i, o_{\partial M_i})$ Chapter9/BoundarySheets · OrientedTameStructure.boundaryOrientation_eq_sum; the left side depends on $\hat{T}_\Theta$ only. *Step 3.* Near each of its points a boundary sheet lies in the one-chart class for m-forms Chapter9/BoundarySheets · OrientedTameStructure.exists_boundarySheet_mem_sheets. *Step 4, the traces.* For $K \in L(\partial S)$ the trace of $\pi^{-1}(K)$ on $\partial_1 M_i$ is measurable, by induction over the generators of $L(\partial S)$: Borel generators have Borel traces, null generators null traces by Step 4 above and $\partial_1 M_i \subseteq \partial M_i$ Chapter9/BoundaryMeasure · OrientedTameStructure.isMeasIn_boundarySheet.

The machinery of §IX.31 for sheet families. The boundary sheets are not the sheets of a branching structure, so (9.20), (9.21) and Lemmas 9.5.7–9.5.11 are proved again for an oriented sheet family: a natural representation on $U(x)$ and finitely many m-dimensional oriented submanifolds with rational weights whose union is $D \cap U(x)$ for a fixed set D closed under morphisms Chapter9/SheetFamily · IsMorSaturated Chapter9/SheetFamily · OrientedSheetFamily, described by a field T' carried along by morphisms Chapter9/SheetFamily · IsNaturalOn Chapter9/SheetFamily · OrientedSheetFamily.lemma_9_5_7 Chapter9/SheetFamily · OrientedSheetFamily.lemma_9_5_9 Chapter9/SheetFamily · OrientedSheetFamily.lemma_9_5_11. An oriented tame structure is the instance $D = \operatorname{supp}(\Theta)$ Chapter9/SheetFamily · OrientedTameStructure.toFamily Chapter9/SheetFamily · isNaturalOn_of_isOrientation. The overlaps and the gluing go as in §IX.31 Chapter9/FamilyMeasure · OrientedSheetFamily.overlap Chapter9/FamilyMeasure · existsUnique_familyMeasure. *The boundary family.* D is the set of points of the support where $\hat{T}_\Theta$ has a term of reduced codimension 1 Chapter9/BoundaryFamily · boundaryStratumSet, closed under morphisms Chapter9/BoundaryFamily · isMorSaturated_boundaryStratumSet since tangent maps of morphisms preserve the reduced codimension; for a structure describing $\hat{T}_\Theta$ it is the union of the $\partial_1 M_i$ in $U(x)$, the weights being positive. $\hat{T}_{\partial\Theta}$ is natural Chapter9/BoundaryFamily · isNaturalOn_boundaryOrientation, and the $(\partial_1 M_i, o_{\partial M_i})$, (σ_i) form a family describing it Chapter9/BoundaryFamily · OrientedTameStructure.boundaryFamily Chapter9/BoundaryFamily · OrientedTameStructure.represents_boundaryFamily.

Theorems 9.5.15 and 9.5.16, first form (V9.67; the form with the text's hypotheses is in §§IX.36–IX.38) Chapter9/BoundaryMeasure · theorem_9_5_15_hyp Chapter9/BoundaryMeasure · theorem_9_5_16_hyp. *For every sheet integration whose null sets are the m-dimensional ones, $n = m + 1$, $m \geq 1$, there is exactly one linear $\omega \mapsto \mu^\partial_\omega$ into the signed measures on $(\partial S, L(\partial S))$ with the printed local formula*, and for the integration over countably many graph charts Chapter9/BoundaryMeasure · theorem_9_5_15_msheets Chapter9/BoundaryMeasure · theorem_9_5_16_msheets. ∂S is compact, being closed in S Chapter9/MeasureGlue · EpGroupoid.isCompact_orbitSupp_boundaryTheta, and the gluing is Chapter9/MeasureGlue · EpGroupoid.theorem_9_5_15_of_overlap. The sum runs over the nonempty $\partial_1 M_i$, the empty set need not belong to the class Chapter9/BoundaryMeasure · OrientedSheetFamily.nonemptyPart, and n-dimensionality is stated explicitly. **Added hypothesis `hcov`**, not derived from the

text: at every point of $\operatorname{supp}(\partial\Theta)$ an oriented tame structure describing $\widehat{T}_\Theta$ whose nonempty boundary sheets lie in the class of the integration. For the multi-chart class this is the finiteness of $\int |\omega|$ over $\partial_1 M_i$ near the corners of M_i, which the text uses tacitly; the difficulty lies where $\partial_1 M_i$ approaches the corners, and compact boundary sheets satisfy it `Chapter9/BoundaryMeasure · OrientedTameStructure.boundarySheet_mem_msheets_of_isCompact` `Chapter9/BoundaryMeasure · hcov_msheets_of_isCompact`. Witnesses: $\Theta = 0$ `Chapter9/BoundaryMeasure · hcov_zero`, and with $\operatorname{supp}(\partial\Theta) \neq \emptyset$ the closed upper hemisphere of §IX.35 `Chapter9/HemisphereWitness · e8w_hcov`. `hcov` is derived from the text's hypotheses (§§IX.36–IX.37), and the case $m = 0$ is §IX.38 (gap G.109, closed).

IX.35 Theorems 9.5.17, 9.5.18 (2017: 9.6, 9.7): Stokes' theorem, and the hemisphere

The text, paraphrased (pp. 449–451). For X with sc-smooth partitions of unity, Θ tame, oriented and compact of dimension n, and ω an sc-differential form of degree $n-1$, $\int_{\widehat{\Theta}} d\omega = \mu^{\partial}_{\omega}(\partial S)$; the effective version asks in addition for the local unique continuation property. The proof covers S by finitely many $|U(x_k)|$ carrying oriented branching structures $(M_i, o_i)_{i\in I_k}$, takes an sc-smooth partition of unity $\beta_0, \dots, \beta_\ell$ constant on the orbits and subordinate to the saturations U_k^* and a further saturated U_0^*, puts $\omega_k = \beta_k\omega$, applies the classical Stokes theorem on each sheet, and sums: $\mu_{d\omega}(S) = \sum_k c_k \sum_{i\in I_k} \sigma_i \int_{(M_i,o_i)} d\omega_k = \sum_k c_k \sum_{i\in I_k} \sigma_i \int_{\partial(M_i,o_i)} \omega_k = \sum_k \mu^{\partial}_{\omega_k}(\partial S) = \mu^{\partial}_{\omega}(\partial S)$, with $c_k = 1/\sharp G_{x_k}$ or $1/\sharp G^{\mathrm{eff}}_{x_k}$.

The Lean proof, step by step.

Step 1 (the cover and the partition of unity). From the sc-smooth partitions of unity of Definition 7.5.5 and the compactness of S one gets finitely many structures and $\beta_0, \dots, \beta_\ell$ as in the text, with $U_0^* = \pi^{-1}(|X| \setminus S)$ `Chapter9/StokesPartition · EP.exists_stokes_partition`. The product $\beta\omega$ is a form of $\Omega^m_{ep,\infty}(X)$ `Chapter9/FunctionTimesForm · EP.epFormsInftySmul`, and the restriction to a level commutes with the evaluation used by the integral `Chapter9/LevelRestrict · formsInftyRestrict_epFormsInftyToObj` `Chapter9/LevelRestrict · epFormsInftyEval_integ_eq_integral`.

Step 2 (Stokes on one sheet). The sheets M_i need not be compact. What makes the classical theorem applicable is that $M_i \cap \operatorname{supp}\beta_k$ is compact, which the text does not state; it follows from the properness of $U(x) \to |U(x)|$ and the compactness of Θ `Chapter9/StokesLocalFormulas · EpGroupoid.NaturalRep.exists_ultrafilter_le_nhds` `Chapter9/StokesLocalFormulas · EpGroupoid.TameBranchingStructure.isCompact_inter`. Then $\int_M (d\omega)|_M = \int_{\partial M} \omega|_M$ on a σ-compact oriented sheet with corners when the restriction has compact support `Chapter9/StokesLocalFormulas · MPolyfold.stokes_formsInftyRestrict_of_isCompact` `Chapter9/StokesLocalFormulas · MPolyfold.OrientedSheet.stokes`. A sheet of an oriented tame structure is such a sheet, with the tangent orientation of o_i `Chapter9/StokesSheet · OrientedTameStructure.orientedSheet`, so $\int_{(M_i,o_i)} d(\beta\omega) = \int_{\partial(M_i,o_i)} \beta\omega$ `Chapter9/StokesSheet · EP.integ_d_smul_eq_boundaryIntegral`, and on one structure $\Phi(d(\beta\omega))(S) = c(x)\sum_i \sigma_i \int_{\partial(M_i,o_i)} \beta\omega$ for every Φ with the local formula of Theorem 9.5.4 or 9.5.5 `Chapter9/StokesSheet · EP.stokes_one_structure` (the second and third equalities of the display). The term $k = 0$ vanishes `Chapter9/StokesSheet · EP.stokes_off_support`.

Step 3 (the sum). Summing over k gives the first three equalities of the display `Chapter9/StokesPartition · EP.stokes_of_partition`, hence Theorems 9.5.17 and 9.5.18 with the right-hand side written as the sum of boundary integrals `Chapter9/StokesPartition · EP.theorem_9_5_17_boundary_sum` `Chapter9/StokesPartition · EP.theorem_9_5_18_boundary_sum`. The measure $\mu_{d\omega}$ is local: it vanishes on sets above which the integrals van-

ish Chapter9/MeasureWholeSheets · measure_eq_zero_of_integ_eq_zero Chapter9/MeasureWholeSheets · measure_univ_eq_of_integ_eq_zero. The last two equalities of the display are two properties of $\omega \mapsto \mu^{\partial}_{\omega}(\partial S)$: the local formula for $\beta\omega$ with $\operatorname{supp}\beta \subseteq U(x)^*$, and vanishing when $\operatorname{supp}\beta$ misses $\operatorname{supp}\Theta$. Every linear functional with these two properties satisfies Stokes' theorem Chapter9/StokesPartition · EP.theorem_9_5_17_of_boundary Chapter9/StokesPartition · EP.theorem_9_5_18_of_boundary, and such a functional exists Chapter9/StokesPartition · EP.exists_boundary_functional.

Step 4 (every dimension $n \geq 1$). The statements of Step 3 were first proved for $n \geq 2$, because in degree 0 the evaluation on frames is cut off. The product rule $(\beta\omega)|_N = \beta\,(\omega|_N)$ is proved in every degree Chapter9/StokesSheetAllDegrees · EP.formsInftyRestrict_epFormsInftySmul_all, and the statements hold for $n = 1$ as well Chapter9/StokesSheetAllDegrees · EP.stokes_one_structure_all Chapter9/StokesPartitionAllDegrees · EP.stokes_of_partition_all Chapter9/StokesPartitionAllDegrees · EP.theorem_9_5_17_boundary_sum_all Chapter9/StokesPartitionAllDegrees · EP.theorem_9_5_18_boundary_sum_all Chapter9/StokesPartitionAllDegrees · EP.exists_boundary_functional_all.

Step 5 (the classical boundary integral is the integral over the stratum). The text's $\int_{\partial(M_i,o_i)}$ is Part I's integral over the faces $\{y_l = 0\}$ of corner charts with signs; μ^{∂} of §IX.34 integrates over the stratum $\partial_1 M_i = \{d_{M_i} = 1\}$ with the boundary orientation $o_{\partial M_i}$ of Definition 9.3.8. The text identifies the two without comment. The face frame $T\iota(\iota_l e_1), \dots, T\iota(\iota_l e_m)$ is positive for $o_{\partial M}$ exactly when the sign of the face matches the reading of o in the chart Chapter9/FaceFrame · MPolyfold.faceFrame_mem_stratumOrientation_iff; the change of variables on a face is Chapter9/FaceChange · FormEval.face_change; the open face piece and the face domain differ by a null set, the corners Chapter9/BoundaryIntegralFaces · CornerCoords.faceSet_ae_eq; one term of Part I's integral is an integral over a face piece Chapter9/BoundaryIntegralFaces · FormEval.face_term_eq, and a weighted integral over the stratum splits over the faces Chapter9/BoundaryIntegralFaces · FormEval.integral_density_eq_sum_face. Hence $\int_{\partial(M_i,o_i)} a = \int_{\partial_1 M_i} a|(\partial_1 M_i, o_{\partial M_i})$ when the nonempty boundary sheet lies in the multi-chart class Chapter9/BoundaryIntegralStratum · EP.boundaryIntegral_eq_msInteg.

Step 6 (the boundary measures are local). $\mu^{\partial}_{\omega}(D) = 0$ when the integrals of ω over the boundary sheets above D vanish Chapter9/BoundaryLocal · boundaryMeasure_eq_zero_of_integ_eq_zero, and $\mu^{\partial}_{\omega}(\partial S) = c(x)\sum_i \sigma_i \int_{\partial_1 M_i} \omega$ for one structure when the integrals vanish off a closed saturated subset of $U(x)^*$ Chapter9/BoundaryLocal · boundaryMeasure_univ_eq. For structures at points off $\operatorname{supp}(\partial\Theta)$ the structure is first restricted into a neighbourhood that avoids $\operatorname{supp}(\partial\Theta)$ Chapter9/BoundaryLocal · OrientedTameStructure.exists_restrict_subset, and both sides vanish.

Step 7 (the theorems). Steps 5 and 6 give the two properties of Step 3 for $\omega \mapsto \mu^{\partial}_{\omega}(\partial S)$. The generic statement is Chapter9/StokesBoundaryMeasure · EP.stokes_of_boundaryMeasure; for every functional with the local formula of Theorem 9.5.15 or 9.5.16 it is Chapter9/StokesBoundaryMeasure · EP.theorem_9_5_17_hyp Chapter9/StokesBoundaryMeasure · EP.theorem_9_5_18_hyp; with the boundary measures themselves Chapter9/StokesBoundaryMeasure · EP.boundaryBranchedMeasure Chapter9/StokesBoundaryMeasure · EP.boundaryBranchedMeasureEff it reads $\int_{\hat\Theta} d\omega = \mu^{\partial}_{\omega}(\partial S)$ and $\oint_{\hat\Theta} d\omega = \oint_{\partial S} \omega\, d\mu^{\partial}$ Chapter9/StokesBoundaryMeasure · EP.theorem_9_5_17_msheets Chapter9/StokesBoundaryMeasure · EP.theorem_9_5_18_msheets, for $\omega \in \Omega^m_{ep,\infty}(X)$ with $m \geq 1$. **Added hypothesis `hcovS`**, not derived from the text: at every point of $\operatorname{supp}\Theta$ an oriented tame structure describing $\hat T_\Theta$ whose sheets lie in one graph chart and whose nonempty boundary sheets lie in the multi-chart class; it gives the `hcov` of §IX.34 Chapter9/StokesBoundaryMeasure · EP.hcovB_of_hcovS. It is derived from the text's hypotheses in §IX.36. For Theorem 9.5.18 the hypotheses of Theorem 9.5.5 are kept as in §IX.32.

The witness. X is the trivial ep-groupoid of the half-space $[0,\infty) \times \mathbb{R}^2$, and $\Theta = 1$ on the closed upper hemisphere $\{|p| = 1\}$, a compact 2-dimensional tame sheet whose boundary stratum is

the equator Chapter9/HemisphereSheet · hemi Chapter9/HemisphereSheet · isSubmanifoldOfDim_hemi Chapter9/HemisphereSheet · boundaryStratum_hemi, with its orientation and $\hat{T}_\Theta$ Chapter9/HemisphereWitness · thetaH Chapter9/HemisphereWitness · hemiOrientation Chapter9/HemisphereWitness · TH. X has sc-smooth partitions of unity Chapter9/HemisphereWitness · e8w_hasScPartitionsOfUnity, $\hat{T}_\Theta$ is an orientation Chapter9/HemisphereWitness · e8w_isOrientation, `hcov` and `hcovS` hold Chapter9/HemisphereWitness · e8w_hcov, and $\partial S \neq \emptyset$ Chapter9/HemisphereWitness · e8w_boundary_nonempty; together Chapter9/HemisphereWitness · e8w_stokes_hypotheses. So Theorem 9.5.17 applies with a nonempty boundary Chapter9/HemisphereStokes · E8W.e8_hemisphere_stokes. The witness has $m = 1$ and no corners, branching or isotropy. As a trivial ep-groupoid it has the local unique continuation property, so it is a witness for Theorem 9.5.18 as well (§IX.38).

With the text's hypotheses. `hcovS` is derived (§IX.36), the case $m = 0$ holds with μ^∂ (§IX.38), and the effective version has the witness of §IX.38; row V9.68 is restated. What remains of gap G.110 is Remark 9.5.20 (§IX.39).

IX.36 The class conditions derived: the corner estimate, and Theorems 9.5.15–9.5.18 for $n \geq 2$

The first proofs of §§IX.34–IX.35 assume `hcov` and `hcovS`: the nonempty boundary sheets $\partial_1 M_i$ of the structures lie in the multi-chart class, so that $\int |\omega|$ over them is finite. Both follow from the text's hypotheses. The earlier estimate for this (800–1,200 lines) assumed that the closed faces of a sheet would be built as submanifolds; the route taken needs none.

Step 1, forms are continuous up to the corners. On a tame sheet M, Part I's chart form of $\omega \in \Omega^m_{ep,\infty}(X)$ is a C^∞ form on the Mathlib manifold with corners M, read in its corner charts, which lie in the maximal atlas (§IX.30).

Step 2, the face change of variables with absolute values. The change of variables of §IX.35, Step 5, is redone with absolute values and lower integrals: on a face set of a corner chart κ, $|\omega|$ on the graph-chart frame is $|\det|$ times the absolute value of the face pull-back Chapter9/CornerFinite · EpGroupoid.FormEval.abs_ev_faceFrame. On the preimage of a compact subset of the chart domain the face pull-back is a continuous function on a compact set, so it is integrable Chapter9/CornerFinite · EpGroupoid.integrableOn_facePullback_of_isCompact.

Step 3, the corner estimate Chapter9/CornerFinite · EpGroupoid.FormEval.boundaryStratum_inter_mem_msheets. If $\partial_1 M \cap V \subseteq K \subseteq M$ with K compact, then $\partial_1 M \cap V$ is in the multi-chart class. Finitely many corner charts, each with a compact piece of its domain, cover K. $\partial_1 M \cap V$ is a countable union of face images, so it is Lindelöf and has a cover by countably many graph charts Chapter9/CornerFinite · EpGroupoid.FormEval.exists_chartCover_of_isLindelof. Each piece of that cover is split by corner chart and pulled back by Step 2. For a fixed corner chart the pieces are disjoint and lie in one compact set of face parameters, so the sum of the integrals of $|\omega|$ is at most a finite sum of integrals over compact sets.

Step 4, shrinking a structure. Every oriented tame structure at x restricts to one with the same natural representation, describing the same $\hat{T}_\Theta$, whose $U(x)$ lies in the interior of a closed neighbourhood t Chapter9/BoundaryCover · EpGroupoid.OrientedTameStructure.exists_restrict_eq. Then $\partial_1 M_i \subseteq M_i \cap t \cap K$, where K is the compact set containing $\operatorname{supp}\Theta \cap U(x)$ given by the properness property, and M_i meets a compact subset of $U(x)$ in a compact set because $M_i \to U(x)$ is proper Chapter9/BoundaryCover · EpGroupoid.LocalBranchingStructure.isCompact_M_inter. Step 3 applies Chapter9/BoundaryCover · EP.boundaryStratum_inter_mem_

msheets Chapter9/BoundaryCover · EP.exists_restrict_boundary_mem_msheets. The natural representation is kept, and with it the local unique continuation property.

Step 5, the theorems. So hcov and hcovS follow from hloc, the reading (d) of "oriented, tame" (§IX.23) Chapter9/BoundaryCover · EP.hcov_of_loc Chapter9/BoundaryCover · EP.hcov_of_loc_isLUC Chapter9/BoundaryCover · EP.hcovS_of_loc Chapter9/BoundaryCover · EP.hcovS_of_loc_isLUC. Theorems 9.5.15 and 9.5.16 hold with the local formula for the structures whose nonempty boundary sheets are in the class Chapter9/StokesTextHypotheses · EP.theorem_9_5_15_class Chapter9/StokesTextHypotheses · EP.theorem_9_5_16_class; such structures exist at every point and every structure restricts to one, so the uniqueness is the text's. The canonical measures are Chapter9/StokesTextHypotheses · EP.boundaryMeasure Chapter9/StokesTextHypotheses · EP.boundaryMeasureEff Chapter9/StokesTextHypotheses · EP.boundaryMeasure_spec. **Theorems 9.5.17 and 9.5.18 as printed,** $m \geq 1$ (V9.68) Chapter9/StokesTextHypotheses · EP.theorem_9_5_17 Chapter9/StokesTextHypotheses · EP.theorem_9_5_18. *For X with sc-smooth partitions of unity, Θ compact, branched, with an orientation $\hat{T}_\Theta$ and* hloc*, and $\omega \in \Omega^m_{ep,\infty}(X)$: $\int_{\hat{\Theta}} d\omega = \mu^\partial_\omega(\partial S)$, with the measure of Theorem 9.5.15; with the local unique continuation property of X, the same for $\oint$ and the measure of Theorem 9.5.16* Chapter9/StokesTextHypotheses · EP.hloc_hasLUC. The hemisphere of §IX.35 satisfies these hypotheses with $\partial S \neq \emptyset$ Chapter9/HemisphereBoundaryMeasure · E8W.k1_hemisphere_stokes.

IX.37 The local formula for every oriented tame structure

The text states the formula of Theorem 9.5.15 for every structure. Step 4 of §IX.36 handles a structure after shrinking it; toward the frontier of $U(x)$ the corner charts of M_i give no uniform bound. The formula holds for every structure all the same, by comparison with other structures.

Step 1, a finite cover. $\partial_1 M_i$ lies in a compact subset of $\operatorname{supp}\Theta$, by the properness property. Cover it by finitely many $U(p)'$ of structures as in §IX.36, whose nonempty boundary sheets are in the class.

Step 2, a common tangent space Chapter9/AllStructures · MPolyfold.k1_exists_tangent_eq. At $z \in \partial_1 M_i \cap U(p)'$ some sheet M'_k of the other structure passes through z with $T_z M'_k = T_z M_i$. Otherwise there is an open $O \ni z$ on which, at every common point, the tangent spaces of M_i and of each M'_k differ. Since $M_i \subseteq \operatorname{supp}\Theta$, every point of $M_i \cap O$ lies on some M'_k, and there the relative tangent space of $M_i \cap M'_k$ is not full. Such points form an $(m+1)$-null set, by the argument of Lemma 9.4.6 (§IX.28), while an open piece of an $(m+1)$-dimensional submanifold is not null.

Step 3, the same stratum. $\{d = 1\}$ is defined through the tangent space alone, so $z \in \partial_1 M'_k$ Chapter9/AllStructures · MPolyfold.k1_mem_boundaryStratum_of_tangent_eq. Whether $d_{M_i} = d_X$, which the tame induced structure does not give, does not matter.

Step 4, domination. $\partial_1 M_i$ lies in the union of finitely many sheets of the class, and a submanifold covered by finitely many sheets of the class is in the class Chapter9/AllStructures · EpGroupoid.FormEval.k1_msheets_of_subset_list. So every nonempty boundary sheet of every oriented tame structure is in the class Chapter9/AllStructures · EP.boundarySheet_mem_msheets_of_loc.

Theorems 9.5.15 and 9.5.16 as printed, $m \geq 1$ (V9.67, restated) Chapter9/AllStructures · EP.theorem_9_5_15 Chapter9/AllStructures · EP.theorem_9_5_16. *For $n = m + 1$ with $m \geq 1$, Θ compact, branched, with an orientation $\hat{T}_\Theta$ and* hloc*, there is exactly one linear $\omega \mapsto \mu^\partial_\omega$ from $\Omega^m_{ep,\infty}(X)$ to the signed measures on $(\partial S, L(\partial S))$ with $\mu^\partial_\omega(K) = \frac{1}{\sharp G_x} \sum_i \sigma_i \int_{K_i} \omega|(\partial_1 M_i, o_{\partial M_i})$ for every $x \in \operatorname{supp}(\partial\Theta)$, every oriented tame structure at x describing $\hat{T}_\Theta$ and every measurable K with $|K| \subseteq |U(x)|$;* with $\sharp G_x^{\text{eff}}$ when X has the local unique continuation property. The canonical measure has the formula for every structure Chapter9/AllStructures · EP.

boundaryMeasure_apply_all. The sum runs over the nonempty $\partial_1 M_i$, which contribute nothing in the text when empty, and n-dimensionality follows from hloc.

IX.38 Dimension one: 0-forms, finite sets of boundary points, and the half-circle

For $n = 1$ the boundary sheets are 0-dimensional and $\omega \in \Omega^0_{ep,\infty}(X)$; the multi-chart class of §IX.34 needs $m > 0$.

Step 1, 0-forms as functions. A 0-form is read as a function on objects, its level-0 value at a smooth point, invariant under morphisms Chapter9/ZeroFormValues · EP.zeroFormEval; its restriction to a sheet is this value Chapter9/ZeroFormValues · EP.formsInftyRestrict_zero_eq. The integral over an oriented point p is $\pm\omega(p)$, the sign from the orientation: the point integration of §IX.31 through this evaluation Chapter9/ZeroFormValues · EP.zeroFormIntegration.

Step 2, finite sets of oriented points Chapter9/FinitePointIntegration · EpGroupoid.finPointIntegration. For a finite set N of smooth points, $\int_A \omega = \sum_{p \in N \cap A} \pm\omega(p)$. This is a sheet integration in the sense of §IX.31 for the class of finite sets Chapter9/FinitePointIntegration · EpGroupoid.finPointSheets, with the null sets of dimension 0: the tangent space of a finite set at one of its points is that of the point Chapter9/FinitePointIntegration · EpGroupoid.submanifoldTangent_finite_eq, and every subset of a finite set is measurable. On sets with at most one point it is the point integration Chapter9/FinitePointIntegration · EpGroupoid.finPointInteg_eq_pointInteg. For 0-forms: Chapter9/FinitePointIntegration · EP.finZeroFormIntegration.

Step 3, the boundary sheets are finite. In a corner chart with values in $[0, \infty)$ the face is one point, so near every point a 1-dimensional tame sheet has at most one point of its boundary stratum Chapter9/BoundaryMeasureDimOne · MPolyfold.exists_isOpen_boundaryStratum_subsingleton. Every oriented tame structure restricts to one whose boundary sheets have at most one point Chapter9/BoundaryMeasureDimOne · EpGroupoid.OrientedTameStructure.exists_boundarySheet_subsingleton, and the class conditions follow from hloc Chapter9/BoundaryMeasureDimOne · EpGroupoid.hcov_dim1_of_loc Chapter9/BoundaryMeasureDimOne · EpGroupoid.hcovEff_dim1_of_loc. The covering argument of §IX.37 then shows that every $\partial_1 M_i$ is finite Chapter9/AllStructuresDimOne · EP.boundarySheet_finite_of_loc Chapter9/AllStructuresDimOne · EP.boundarySheet_mem_finPointSheets_of_loc.

Step 4, Part I's boundary integral. For a 1-dimensional sheet with one boundary point p, Part I's $\int_{\partial M} \omega$ is $\pm\omega(p)$: the Lebesgue measure on $\mathbb{R}^0$ is a Dirac measure, and the face sign is that of §IX.35, Step 5, at $m = 0$ Chapter9/FaceIntegralDimOne · EpGroupoid.boundaryIntegral_eq_pointInteg Chapter9/FaceIntegralDimOne · EP.boundaryIntegral_eq_zeroFormIntegration.

Step 5, Stokes. The locality argument of §IX.35, Step 6, is redone for any sheet integration Chapter9/StokesDimOne · EpGroupoid.boundaryMeasure_univ_eqI and combined with the boundary-sum form of §IX.35, Step 4 Chapter9/StokesDimOne · EP.stokes_of_boundaryMeasure_dim1.

The theorems for $n = 1$ (V9.67, V9.68). Theorems 9.5.15 and 9.5.16 with the formula for every oriented tame structure, $\int_{K_i} \omega | (\partial_1 M_i, o) = \sum_{p \in K_i} \pm\omega(p)$ Chapter9/AllStructuresDimOne · EP.theorem_9_5_15_dim1_all Chapter9/AllStructuresDimOne · EP.theorem_9_5_16_dim1_all, first proved for the structures whose boundary sheets are points Chapter9/BoundaryMeasureDimOne · EP.theorem_9_5_15_dim1 Chapter9/BoundaryMeasureDimOne · EP.theorem_9_5_16_dim1 Chapter9/EffectiveDimOneLUC · EP.theorem_9_5_16_dim1_isLUC. Theorems 9.5.17 and 9.5.18: $\int_{\hat{\Theta}} d\omega = \mu^{\partial}_{\omega}(\partial S)$ Chapter9/StokesDimOne · EP.theorem_9_5_17_dim1 Chapter9/StokesDimOne · EP.theorem_9_5_18_dim1 Chapter9/EffectiveDimOneLUC · EP.theorem_9_5_18_dim1_isLUC, with the measures Chapter9/StokesDimOne · EP.

boundaryBranchedMeasureDim1 Chapter9/StokesDimOne · EP.boundaryBranchedMeasureEffDim1, which are those of the $n = 1$ Theorems 9.5.15 and 9.5.16 Chapter9/AllStructuresDimOne · EP.boundaryBranchedMeasureDim1_apply_all Chapter9/AllStructuresDimOne · EP.boundaryBranchedMeasureEffDim1_apply_all. The hypotheses are the text's.

Witnesses with nonempty boundary. $n = 1$. $X = [0,\infty) \times \mathbb{R}$ as a trivial ep-groupoid, and $\Theta = 1$ on the closed half-circle $\{|p| = 1\}$, the image of the sc$^+$-retraction $p \mapsto p/|p|$ of $X \setminus \{0\}$: a compact, tame, 1-dimensional submanifold Chapter9/HalfCircleSheet · K2Arc.isSubmanifoldOfDim_arc Chapter9/HalfCircleSheet · K2Arc.isTameSubMPolyfold_arc whose boundary stratum is its two end points on $\{0\} \times \mathbb{R}$ Chapter9/HalfCircleSheet · K2Arc.boundaryStratum_arc, oriented by a field that is a unit tangent on the circle Chapter9/HalfCircleWitness · K2Arc.arcOrientation. All hypotheses of Theorems 9.5.15–9.5.18 for $n = 1$ hold, with $\operatorname{supp}(\partial\Theta) \neq \emptyset$ Chapter9/HalfCircleWitness · K2Arc.arc_hloc Chapter9/HalfCircleWitness · K2Arc.arc_isLUC Chapter9/HalfCircleWitness · K2Arc.k2_arc_hypotheses, and Stokes' theorem applies Chapter9/HalfCircleWitness · K2Arc.k2_arc_stokes Chapter9/HalfCircleWitness · K2Arc.k2_arc_stokes_eff. $n = 2$, *the effective version.* Every natural representation of a trivial ep-groupoid has the local unique continuation property Chapter9/HemisphereStokesEffective · E8W.hasLUC_trivial, so the hemisphere of §IX.35 has it Chapter9/HemisphereStokesLUC · E8W.e8w_isLUC, and Theorem 9.5.18 applies with $\partial S \neq \emptyset$ Chapter9/HemisphereStokesLUC · E8W.k2_hemisphere_stokes_eff Chapter9/HemisphereStokesEffective · E8W.e8_hemisphere_stokes_eff. Neither witness has corners, branching or nontrivial isotropy; Remark 9.5.20 is about the last (§IX.39).

IX.39 Remark 9.5.20 (2021 pp. 451–452): the example, in part

The text. $X = \{(-1,0)\} \cup ((-1,1) \times B) \cup \{(1,0)\} \subseteq \mathbb{R} \times \mathbb{C}$ with an M-polyfold structure, $\mathbb{Z}_3$ rotating the $\mathbb{C}$-factor, $M = [-1,1] \times \{0\}$, $\Theta(t,z) = \delta_0(z)$ oriented by $[-1,1]$, and $f(t,z) = \phi(t)$. The remark computes $\oint_\Theta df = \frac{1}{3}(\phi(1) - \phi(-1))$ and observes that $\partial X = \{(\pm 1, 0)\}$ is a sub-ep-groupoid whose points have trivial effective isotropy, while in X it is $\mathbb{Z}_3$: the boundary integral of f is $\frac{1}{3}(\phi(1) - \phi(-1))$ read in X, in accordance with Stokes' theorem, and $\phi(1) - \phi(-1)$ read in ∂X.

The M-polyfold Chapter9/DimensionJumpPolyfold · K3.P. The text says only that X can be given an M-polyfold structure. It is given one with one chart, onto an sc-smooth retract of the partial quadrant $[0,\infty)^2 \times (c_0 \oplus c_0)$ in $E = \mathbb{R}^2 \oplus c_0 \oplus c_0$, with the weighted scale of Remark 4.1.3's example (§IV.27). The retraction is $R(p,a,b) = (2p/|p|, \pi_{\tau(p)}a, \pi_{\tau(p)}b)$ Chapter9/DimensionJumpRetract · K3.Rt Chapter9/DimensionJumpRetract · K3.mem_0_iff, with Remark 4.1.3's family π_τ (rank one for $\tau > 0$, zero for $\tau \leq 0$) composed with $\tau(p) = p_0 p_1$ Chapter9/DimensionJumpRetract · IsLossFamily.comp_contDiff Chapter9/DimensionJumpRetract · IsLossFamily.diag. Its retract is the quarter circle of radius 2 carrying a plane over each interior point and a point over each end. The chart is $\psi(t,z) = (2(\cos\theta, \sin\theta), \operatorname{Re} w\,\beta_\tau, \operatorname{Im} w\,\beta_\tau)$ with $\theta = \pi(1+t)/4$ and $w = z/\sqrt{1-|z|^2}$ Chapter9/DimensionJumpPolyfold · K3.chart. The degeneracy index is 1 at $(\pm 1, 0)$ and 0 elsewhere Chapter9/DimensionJumpPolyfold · K3.degIndex_eq; the lower bound at the ends is Theorem 2.4.12, from an inward vector in the tangent space of the retract Chapter9/DimensionJumpPolyfold · K3.scDeriv_end. So $\partial X = \{(-1,0),(1,0)\}$ Chapter9/DimensionJumpPolyfold · K3.boundary_eq.

The groupoid Chapter9/CyclicGroupoidIsotropy · K3.ε. $\mathbb{Z}_3$ acts by $k \cdot (t,z) = (t, \omega^k z)$, sc-smoothly, since in the chart it is the restriction of the rotation of (a,b), an sc-operator commuting with R Chapter9/CyclicGroupoidIsotropy · K3.isScSmoothMap_smul. Its non-effective part is $\{1\} \times X$ Chapter9/CyclicGroupoidIsotropy · K3.nonEffectivePart_ε, which is closed, so $\varepsilon = \mathbb{Z}_3 \ltimes X$ has the local unique continuation property Chapter9/CyclicGroupoidIsotropy · K3.isLUC_ε. The effective isotropy has three elements on M Chapter9/CyclicGroupoidIsotropy · K3.card_effIsotropy_of_snd_eq_zero and one off M Chapter9/

CyclicGroupoidIsotropy · K3.card_effIsotropy_of_snd_ne_zero. ∂X is a saturated sub-M-polyfold Chapter9/CyclicGroupoidIsotropy · K3.isEpSubgroupoid_boundary, and ε_B is the sub-ep-groupoid of Proposition 7.1.22 on it Chapter9/CyclicGroupoidIsotropy · K3.εB. At a point of ∂X the isotropy group has three elements in ε and in ε_B Chapter9/CyclicGroupoidIsotropy · K3.card_isotropy_εB, and the effective isotropy has three in ε and one in ε_B Chapter9/CyclicGroupoidIsotropy · K3.card_effIsotropy_εB: every morphism of ε_B acts trivially near its points. Collected: Chapter9/CyclicGroupoidIsotropy · K3.remark_9_5_20_effIsotropy.

Not formalized (gap G.110, in part). Θ with its orientation and `hloc` at the infinite-dimensional ends; sc-smooth partitions of unity of ε (Corollary 7.6.6 asks for a Hilbert space on level 0, and here E_0 contains c_0); f as a 0-form; $\oint_{\partial\Theta} df = \frac{1}{3}(\phi(1) - \phi(-1))$, by the $n = 1$ theorems of §IX.38 and the local formula at the two ends; the integral of f over $\partial\Theta$ in ε_B; and that ∂X is a smooth submanifold, shown at each of its two points only. Estimated at 2,340–3,790 lines (Findings, Chapter 9, item 120).

Part X. Equivalences and localization (HWZ Chapter 10, §§10.1–10.5 and Appendix §§10.6.1–10.6.3 (2017 §§10.1–10.5))

Chapter 10 continues Part II; its numbers and pages are those of the book (Springer 2021, pp. 461–520), with the 2017 text's in parentheses (2017 pp. 333–374). It studies the sc-smooth functors between ep-groupoids that should become invertible once ep-groupoids are taken as models of polyfolds. §10.1 defines equivalences (Definition 10.1.1 (2017: 10.1)), characterizes them as the equivalences of categories that are local sc-diffeomorphisms on objects (Lemma 10.1.2 (2017: 10.1)), builds the refinement along an open covering (Proposition 10.1.3 (2017: 10.1)), shows that natural equivalence, the two-out-of-three property and the tangent functor respect equivalences (Definition 10.1.4, Propositions 10.1.5, 10.1.6, Theorem 10.1.7 (2017: 10.2, 10.2, 10.3, 10.1)) and, mostly new in 2021, that the properties of Chapter 7 are invariant (Remarks 10.1.8, 10.1.11, 10.1.12, Propositions 10.1.9, 10.1.10, 10.1.13, 10.1.14, 10.1.16–10.1.19, Example 10.1.15). §10.2 constructs the weak fibred product (Definition 10.2.1 (2017: 10.3), Theorem 10.2.2 (2017: 10.2), Remark 10.2.3 (2017: 10.2)). §10.4 carries all this to strong bundles: strong bundle equivalences (Definition 10.4.1 (2017: 10.10)), the pull-back and push-forward of section functors (Propositions 10.4.2–10.4.4, Theorem 10.4.5 (2017: 10.7–10.9, 10.8)), natural transformations of strong bundle functors (Definitions 10.4.8, 10.4.10, Remark 10.4.9 (2017: 10.11, 10.12, 10.4)) and the category $\mathcal{SEP}$ (Definition 10.4.11 (2017: 10.13)). §10.3, treated here after §10.4 in the order of the verified edition, inverts the equivalences: diagrams $X \xleftarrow{F} A \xrightarrow{\Phi} Y$ with F an equivalence, their refinement and equivalence (Definitions 10.3.1, 10.3.3, 10.3.5, Lemmas 10.3.2, 10.3.4, 10.3.6, Definition 10.3.7 (2017: 10.4–10.7, 10.3–10.5)), the composition of classes (Theorem 10.3.8 (2017: 10.3), Appendix §10.6.1), generalized isomorphisms (Definition 10.3.9, Theorem 10.3.10 (2017: 10.8, 10.4), Appendix §10.6.2), the category $\mathcal{EP}(E^{-1})$ with the functors i and $|\cdot|$ (Proposition 10.3.11, Definition 10.3.12, Theorems 10.3.14, 10.3.15 (2017: 10.6, 10.9, 10.5, 10.6)) and the invariance of the properties of Chapter 7 under generalized isomorphisms (Propositions 10.3.16, 10.3.17, Remark 10.3.18, Theorem 10.3.19, Definition 10.3.20, Theorem 10.3.21). §10.5, treated after §10.3, repeats the localization for strong bundles: diagrams $W \xleftarrow{\Phi} W'' \xrightarrow{\Psi} W'$ with Φ a strong bundle equivalence, their classes, the maps $[d]$, $|[D]|$ and the homomorphisms γ (pp. 504–506), the category $\mathcal{SEP}(F^{-1})$ and generalized strong bundle isomorphisms (Definitions 10.5.1, 10.5.2 (2017: 10.14, 10.15), Remark 10.5.3), the push-forward of section functors (Theorem 10.5.4 (2017: 10.9), Remark 10.5.5) and the local regularity property (Proposition 10.5.6, Theorem 10.5.7 (2017: 10.10)). Appendix §10.6.3, new

in 2021, gives the example behind Remark 10.1.8 on a weighted Sobolev scale; §10.1 also introduces the full subcategory $\mathcal{EP}_{lreg}$ (p. 461) and §10.4 the strong bundle versions of Propositions 10.1.9 and 10.1.10 (Propositions 10.4.6, 10.4.7).

What is proved, and what is not. Every gap of Chapter 10 is closed (G.111–G.127): each statement of the chapter is proved, and two, Theorems 10.3.19 and 10.5.7, do not hold as we read them and are proved for an effective target. Nothing in the chapter is open or formalized only in part. *§10.1.* All definitions are formalized. Lemma 10.1.2 (with its converse), Propositions 10.1.3, 10.1.5, 10.1.6, 10.1.13, 10.1.14, 10.1.16–10.1.19, Theorem 10.1.7, Remarks 10.1.11 and 10.1.12 and Example 10.1.15 are proved, several in a stronger form. Proposition 10.1.9 is proved, and Proposition 10.1.10 with (LR) on one side only (§§X.5, X.7; G.113–G.115). The subcategory $\mathcal{EP}_{lreg}$ is §X.27 (G.111). Remark 10.1.8 with the example of Appendix §10.6.3, on the weighted Sobolev scale as printed, is §X.28 (G.112). Two results the text quotes or leaves to the reader are proved: Proposition 10.1.5, and the fullness and faithfulness of TF in Theorem 10.1.7. *§10.2.* All claims of Theorem 10.2.2 are proved, including that the structures are those induced from the triple products (§X.29; G.116), and so is Remark 10.2.3. *§10.4.* All definitions are formalized, and Propositions 10.4.2–10.4.4, Remark 10.4.9 and the equivalence of Definitions 10.4.8 and 10.4.10 are proved. Theorem 10.4.5 is proved with its Fred part (§X.31; G.121); the sc-smoothness of the push-forward, "easily verified" in the text, is proved too. Propositions 10.4.6 and 10.4.7 are §X.32 (G.122), with Definition 8.4.2 read for strong bundle isomorphisms of $W|U(x)$; Proposition 10.4.7 is proved with the property for the target only. *§10.3.* All definitions are formalized, with the proofs of the appendix. Proved: (E1)–(E3), Lemmas 10.3.2, 10.3.4, 10.3.6, Theorems 10.3.8, 10.3.10, 10.3.14, 10.3.15, Propositions 10.3.11, 10.3.16, 10.3.17, Remark 10.3.18 and Theorem 10.3.21 (§§X.16–X.20; G.118 closed by §X.20, G.119 by §X.23). The universal property of the localization (G.117) is §X.30. Theorem 10.3.19 does not hold as we read it, and holds for an effective target (§X.20; G.120, settled). *§10.5.* Formalized: the diagrams, their refinements and classes, $[d]$, $|[D]|$, the square $|\mathcal{D}|$, γ, Definitions 10.5.1 and 10.5.2, and $\mathcal{SEP}(F^{-1})$ as a category through the weak fibred product of strong bundles (§§X.21, X.22). (10.24) with generalized vertical maps and the local expressions q, Q are §X.33 (G.124). Proved: Remark 10.5.3, with both directions of the strong bundle Theorem 10.3.10 (§§X.22, X.34; G.123); Theorem 10.5.4 with its Fred part and as a linear isomorphism (§§X.23, X.31; G.125); Remark 10.5.5, with an example; and Proposition 10.5.6 (§§X.23, X.32; G.126). Theorem 10.5.7 does not hold as we read it, and holds over an effective base of the target (§X.23; G.127, settled). Remark 10.3.13 and the sentences on "smaller models" in Remark 10.2.3 have no formal content. *The narrower row.* There is one: V10.66, Theorem 10.3.19 for an effective target. The effectiveness of Y is an added hypothesis, not derived from the text; without it the theorem does not hold as we read it (`not_theorem_10_3_19`). Its satisfiability witness is the point (§X.20). The strong bundle analogue is part of the restated row V10.67, with the same reason: Theorem 10.5.7 over an effective base of the target, with (LR) of a base or the local regularity property of the target bundle (§X.23).

Six structural choices. (1) *Equivalences as a structure.* `EpFunctor.IsEquivalence` has the four conditions of Definition 10.1.1 as fields, with full and faithful stated on the sets of morphisms; Mathlib's `Functor.IsEquivalence` of the underlying functor is derived (§X.1). (2) *Indexed coverings.* The refinement $X_{\mathcal{U}}$ takes a family $(U_i)_{i\in\iota}$ of open sets; objects and morphisms are open subsets of products with the discrete ι (§X.2). (3) *Iterated fibred products.* The weak fibred product is built from Part I's fibred products, twice, so that its M-polyfold structures come with their universal properties; the admissibility, F or G a local sc-diffeomorphism on objects, is all that the construction uses (§X.9). (4) *Total pull-backs and push-forwards.* Φ^* and Φ_* are defined on all maps, by the zero of the fibre where needed, and the push-forward with one choice of x and σ made for all; all statements are about section functors, where the choice does not matter

(§X.12). (5) *Diagrams one universe up.* A diagram contains its middle ep-groupoid as an object of $\mathcal{EP}$, so the classes of diagrams form a type in the universe of the objects of $\mathcal{EP}$ and $\mathcal{EP}(E^{-1})$ is a large category like $\mathcal{EP}$; compositions are written in Mathlib's order, d.comp e for the text's $[e] \circ [d]$ (§X.16). (6) *The weak fibred product of strong bundles as a pull-back.* The text leaves it to the reader; it is the pull-back of W'' along π_Z, so that one projection is a strong bundle equivalence by construction and the squares in the proofs of the composition commute strictly, by the fibrewise injectivity of strong bundle equivalences; the generalized strong bundle maps, defined as the classes of the equivalence relation generated by having a common refinement, are the text's classes by the transitivity (§§X.21, X.22).

- `Chapter10/StrongBundleWeakFibredProductPullback`: pull-backs of strong bundles along functors, transports along natural transformations, fibrewise inverse lifts.
- `Chapter10/StrongBundleWeakFibredProduct`: the weak fibred product of strong bundles and the

strong bundle Theorem 10.2.2.

- `Chapter10/StrongBundleLocalizationCategory`: the strong bundle Lemma 10.3.4 and Theorem 10.3.8, $\mathcal{SEP}(F^{-1})$ as a category with its localization functor, one direction of the strong bundle Theorem 10.3.10.
- `Chapter10/LocalizationLREffectiveBundle`: Theorem 10.5.7 over an effective base of the target, with (LR) of a base.
- `Chapter10/LocalizationLRBundleBase`: Definition 8.4.2 read for strong bundle isomorphisms of $W|U(x)$, Proposition 10.4.7 on the bases, Theorem 10.5.7 over an effective base from that property.
- `Chapter10/LocalRegularitySubcategory`: the subcategory $\mathcal{EP}_{lreg}$ of $\mathcal{EP}$ and of $\mathcal{EP}(E^{-1})$.
- `Chapter10/ZhouExampleRealScale`: Remark 10.1.8 and Appendix §10.6.3 as printed, on the scale $\mathbb{R} \oplus H^{m,\delta_m}(\mathbb{R})$.
- `Chapter10/ZhouExample`: the same example with the projections of Remark 4.1.3.
- `Chapter10/WeakFibredProductTriple`: the structures of Theorem 10.2.2 induced from the triple products.
- `Chapter10/LocalizationUniversal`: the universal property of $i : \mathcal{EP} \to \mathcal{EP}(E^{-1})$.
- `Chapter10/FredholmEquivalence`: the Fred parts of Theorems 10.4.5 and 10.5.4.
- `Chapter10/SectionFunctorLinear2021`: the push-forwards of Theorems 10.4.5 and 10.5.4 as linear isomorphisms.
- `Chapter10/StrongBundleLocalIso`: local strong bundle isomorphisms between two strong bundles, transports along families of morphisms.
- `Chapter10/StrongBundleLocalRegularity`: Propositions 10.4.6 and 10.5.6.
- `Chapter10/StrongBundleLocalFamilies`: Proposition 10.4.7.
- `Chapter10/StrongBundleDiagram`: the square (10.24) in $\mathcal{EP}(E^{-1})$ and the germ q.
- `Chapter10/StrongBundleDiagramLift`: the lift Q and (10.25).
- `Chapter10/StrongBundleIsoConverse`: the converse half of the strong bundle Theorem 10.3.10.

Throughout, $X = (X, \mathbf{X})$, Y, Z are ep-groupoids as in Part VII, s, t the source and target, $|X|$ the orbit space and $|F| : |X| \to |Y|$ the induced map, G_x the isotropy group, T_x its subgroup acting trivially near x and $\mathbf{X}^T$ the non-effective part (§VII.3). Functors are sc-smooth functors (`EpFunctor`), and natural transformations those of Chapter 8 (`EpNatTrans`).

X.1 Definition 10.1.1 (2017: 10.1) and Lemma 10.1.2 (2017: 10.1)

Definition 10.1.1 (2017: 10.1) (V10.1) `Chapter10/Equivalence · EpFunctor.IsEquivalence` `Chapter10/Equivalence · EP.equivalences`. The four fields are fullness and faithfulness on the sets of morphisms, $|F|$ a homeomorphism, and F a local sc-diffeomorphism on objects. Fullness and faithfulness are those of Mathlib for the underlying functor `Chapter10/Equivalence · GroupoidFunctor.full_iff` `Chapter10/Equivalence · GroupoidFunctor.faithful_iff`, and so is essential surjectivity `Chapter10/Equivalence · GroupoidFunctor.essSurj_iff`. *Step 1, essential surjectivity.* For $y \in Y$, $|F|$ is onto, so $[y] = [F(x)]$ for some x, that is a morphism $F(x) \to y$ exists `Chapter10/Equivalence · EpFunctor.IsEquivalence.essSurj` `Chapter10/Equivalence · EpFunctor.IsEquivalence.exists_iso`. *Step 2, the morphism sets.* Every $\psi : F(x) \to F(x')$ is $F(\varphi)$ `Chapter10/Equivalence · EpFunctor.IsEquivalence.exists_mor_eq` and F is injective on morphisms with the same ends `Chapter10/Equivalence · EpFunctor.IsEquivalence.mor_injective`. *Step 3, the class E.* The identity is an equivalence `Chapter10/Equivalence · EpFunctor.IsEquivalence.id`, composites are `Chapter10/Equivalence · EpFunctor.IsEquivalence.comp` (the composite of homeomorphisms and of local sc-diffeomorphisms, with $|G \circ F| = |G| \circ |F|$ `Chapter10/Equivalence · GroupoidFunctor.toFunctor_`

comp), so `EP.equivalences` is a multiplicative class. Witness: the functor from the pair groupoid of $\mathbb{Z}$ (one morphism between any two integers) to the point Chapter10/Equivalence · EpGroupoid.Examples.pairToPoint Chapter10/Equivalence · EpGroupoid.Examples.isEquivalence_pairToPoint, a local sc-diffeomorphism because $\mathbb{Z}$ is discrete Chapter10/Equivalence · EpGroupoid.Examples.isLocalScDiffeo_discrete.

Local sc-diffeomorphisms at a point. The local property of Definition 10.1.1 (3) is localized Chapter10/Equivalence · MPolyfold.IsLocalScDiffeoAt Chapter10/Equivalence · MPolyfold.isLocalScDiffeo_iff_forall Chapter10/Equivalence · MPolyfold.IsLocalScDiffeo.at, with the rules used below: composition Chapter10/Equivalence · MPolyfold.IsLocalScDiffeoAt.comp, agreement near the point Chapter10/Equivalence · MPolyfold.IsLocalScDiffeoAt.congr, and the two cancellation rules: if $g \circ f$ and g are local sc-diffeomorphisms at x and $f(x)$, so is f at x Chapter10/Equivalence · MPolyfold.IsLocalScDiffeoAt.of_comp_left; if $g \circ f$ and f are, so is g at $f(x)$ Chapter10/Equivalence · MPolyfold.IsLocalScDiffeoAt.of_comp_right.

Lemma 10.1.2 (2017: 10.1) (V10.2) Chapter10/Equivalence · EpFunctor.lemma_10_1_2 Chapter10/Equivalence · EpFunctor.isEquivalence_iff. *Step 1, $|F|$ is bijective.* For a functor of groupoids, $|F|$ is injective when F is full ($F(x) \cong F(x')$ lifts to $x \cong x'$) Chapter10/Equivalence · GroupoidFunctor.injective_orbitMap_of_full, surjective exactly when F is essentially surjective Chapter10/Equivalence · GroupoidFunctor.surjective_orbitMap_iff, hence bijective for an equivalence of categories Chapter10/Equivalence · GroupoidFunctor.bijective_orbitMap_of_isEquivalence. *Step 2, $|F|$ is a homeomorphism.* $|F|$ is continuous by the universal property of the quotient Chapter10/Equivalence · EpFunctor.continuous_orbitMap; it is open because F is a local sc-diffeomorphism, hence open, on objects and the orbit maps are open (Proposition 7.1.8 (2017: 7.1)) Chapter7/Basic · EpGroupoid.proposition_7_1_8 Chapter10/Equivalence · EpFunctor.isOpenMap_orbitMap. *Step 3, the converse.* An equivalence is full, faithful and essentially surjective (§X.1), so an equivalence of categories Chapter10/Equivalence · EpFunctor.IsEquivalence.isEquivalence_toFunctor. *Not invertible.* The functor $\mathbb{Z} \to \mathrm{pt}$ above has no left inverse on objects Chapter10/Equivalence · EpGroupoid.Examples.not_exists_leftInverse_pairToPoint.

X.2 Proposition 10.1.3 (2017: 10.1): the refinement $X_{\mathcal{U}}$

The construction Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.objSet Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.morSet Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.groupoidStr. A covering is a family of open sets U_i with every object in some U_i; the trivial covering by X is one Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.univ. The text indexes the covering by itself and writes (U, x); the index type is the formal reading. The objects (i, x), $x \in U_i$, form an open subset of $\iota \times X$ Chapter10/EquivalenceRefinement · isOpen_of_discrete_left, the morphisms (i, φ, j) one of $(\iota \times \iota) \times \mathbf{X}$, and both get the open-subset M-polyfold structures Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.objPolyfold Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.morPolyfold, which need a nonempty set: the object set of X is assumed nonempty (for an empty X there is nothing to prove). Products with a discrete space keep the paracompactness and metrizability Chapter10/EquivalenceRefinement · paracompactSpace_discrete_prod.

$X_{\mathcal{U}}$ is an ep-groupoid Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.epGroupoid. *Step 1, local sc-diffeomorphisms.* On a product with a discrete factor a map that is a local sc-diffeomorphism on each sheet is one Chapter10/EquivalenceRefinement · isLocalScDiffeo_sheet Chapter10/EquivalenceRefinement · isLocalScDiffeo_snd_discrete; $s(i, \varphi, j) = (i, s(\varphi))$ and $t(i, \varphi, j) = (j, t(\varphi))$ are local sc-diffeomorphisms Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.isLocalScDiffeo_src Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.isLocalScDiffeo_tgt, through the restriction

rules for open subsets Chapter10/EquivalenceRefinement · MPolyfold.isScSmoothOn_restrictOpen_iff Chapter10/EquivalenceRefinement · MPolyfold.isScSmoothMap_restrict Chapter10/EquivalenceRefinement · MPolyfold.isLocalScDiffeoAt_restrict. *Step 2, unit, inverse, multiplication.* They are those of X on each sheet, sc-smooth by the continuity on the discrete factor Chapter10/EquivalenceRefinement · isScSmoothOn_discrete_of_continuousOn Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.isScSmoothMap_unit Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.isScSmoothMap_inv Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.isScSmoothCompSheet. *Step 3, properness.* At (i, x) take a neighbourhood V_0 of x with the properness property of X and an open $V(x)$ with $\mathrm{cl}\, V(x) \subseteq U_i \cap V_0$; then t is proper on $s^{-1}(\mathrm{cl}(\{i\} \times V(x)))$ Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.exists_isProperMap. The proof uses ultrafilters in place of the text's sequences; the index j of a limit is determined by the sheet, which is clopen.

Proposition 10.1.3 (2017: 10.1) (V10.3) Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.proposition_10_1_3. $F(i, x) = x$, $F(i, \varphi, j) = \varphi$ Chapter10/EquivalenceRefinement · EpGroupoid.OpenCover.functor is a local sc-diffeomorphism on objects, faithful because a morphism of $X_{\mathcal{U}}$ is determined by its ends and its φ, full because $\psi : x \to x'$ lifts to (i, ψ, j), and essentially surjective because every x lies in some U_i; Lemma 10.1.2 applies. The text writes the morphism as (U, φ, v) in the formula for F; we read (U, φ, V) (possible misprint). *Witness.* The covering $\{x > -1\}$, $\{x < 1\}$ of $\mathbb{Z}/2 \ltimes \mathbb{R}$ Chapter10/EquivalenceRefinement · EpGroupoid.Examples.reflectionCover gives an equivalence Chapter10/EquivalenceRefinement · EpGroupoid.Examples.isEquivalence_reflectionCover that is not injective on objects Chapter10/EquivalenceRefinement · EpGroupoid.Examples.not_injective_reflectionCover_obj.

X.3 Definition 10.1.4 (2017: 10.2), Propositions 10.1.5 and 10.1.6 (2017: 10.2 and 10.3)

Definition 10.1.4 (2017: 10.2) (V10.4) Chapter10/Equivalence · definition_10_1_4. The definition is Chapter 8's Definition 8.1.13 Chapter8/Basic · EpNatTrans Chapter8/Basic · EpFunctor.NaturallyEquivalent; the claims after it, that $\simeq$ is an equivalence relation and compatible with composition, are Chapter 8's Chapter8/NatTrans · EpFunctor.naturallyEquivalent_equivalence Chapter8/NatTrans · EpFunctor.NaturallyEquivalent.comp_left Chapter8/NatTrans · EpFunctor.NaturallyEquivalent.comp_right. A natural transformation of ep-groupoids is a natural isomorphism of the underlying functors, every morphism being invertible Chapter10/Equivalence · EpNatTrans.toNatIso.

Proposition 10.1.5 (2017: 10.2) (V10.5) Chapter10/Equivalence · EpFunctor.proposition_10_1_5 Chapter10/Equivalence · EpFunctor.IsEquivalence.of_natTrans. The text quotes it from the literature. *Step 1.* $\tau : X \to \mathbf{X}'$ is continuous Chapter10/Equivalence · EpNatTrans.continuous_app and, since $s \circ \tau = F$ with F and s local sc-diffeomorphisms, a local sc-diffeomorphism Chapter10/Equivalence · EpNatTrans.isLocalScDiffeo_app. *Step 2.* $G = t \circ \tau$ is a composite of local sc-diffeomorphisms Chapter10/Equivalence · EpNatTrans.isLocalScDiffeo_obj. *Step 3.* The underlying functors are naturally isomorphic, so G is an equivalence of categories with F, and Lemma 10.1.2 applies. The symmetric statement follows from the symmetry of $\simeq$.

Proposition 10.1.6 (2017: 10.3) (V10.6) Chapter10/Equivalence · EpFunctor.proposition_10_1_6. *Step 1, categories.* Φ is an equivalence of categories since F and $\Phi \circ F$ are (Mathlib's two-out-of-three). *Step 2, objects in the image.* At $F(x)$, $\Phi \circ F$ and F are local sc-diffeomorphisms at x, so Φ is one at $F(x)$ (the right cancellation rule). *Step 3, transport.* The text's argument stops here; an arbitrary y receives a morphism $\sigma : F(x) \to y$ Chapter10/Equivalence · EpFunctor.IsEquivalence.exists_iso, and the local sc-diffeomorphism property of a functor passes from $s(\sigma)$ to $t(\sigma)$ Chapter10/Equivalence · EpFunctor.isLocalScDiffeoAt_obj_tgt: near σ, $t \circ \tau = \Phi \circ t \circ \dots$ is written with a local inverse τ of s, and on morphisms Φ is a local sc-

diffeomorphism where it is one on objects `Chapter10/Equivalence · EpFunctor.isLocalScDiffeoAt_mor` `Chapter10/Equivalence · EpFunctor.isLocalScDiffeo_mor`. *Step 4.* Lemma 10.1.2. The text's $|\Phi| : |X| \to |Y|$ in the proof is read $|\Phi| : |Y| \to |Z|$ (possible misprint).

X.4 Theorem 10.1.7 (2017: 10.1): the tangent of an equivalence

Theorem 10.1.7 (2017: 10.1) (V10.7) `Chapter10/Equivalence · EpFunctor.theorem_10_1_7`. TF is Chapter 8's tangent functor `Chapter8/TangentEp · EpFunctor.tangent`; the text proves the homeomorphism and the local sc-diffeomorphism property and leaves full and faithful to the reader. Here all goes through Lemma 10.1.2. *Step 1, local sc-diffeomorphism.* The tangent of a local sc-diffeomorphism is one (Part I). *Step 2, faithful.* A tangent morphism (φ, v) is determined by φ and its source vector `Chapter8/TangentEp · EpGroupoid.tangent_ext`, and F is faithful. *Step 3, full.* For $(\psi, w) : TF(x, a) \to TF(x', a')$, $\psi = F(\varphi)$ by fullness of F; φ lifts to a tangent morphism with source (x, a) `Chapter8/TangentEp · EpGroupoid.exists_tSrc_eq'`, whose image under TF has the same source as (ψ, w), and the targets agree since TF is injective on the tangent fibre at x' `Chapter8/TangentLocal · MPolyfold.IsLocalScDiffeo.injOn_tangentFiber`. *Step 4, essentially surjective.* For (y, b) take $\psi : F(x) \to y$, lift ψ^{-1} with source (y, b) and use that TF maps T_xX onto $T_{F(x)}Y$ `Chapter8/TangentLocal · MPolyfold.IsLocalScDiffeo.tangentFiber_subset_image`, then invert `Chapter8/Basic · EpGroupoid.tInv`.

X.5 Remarks 10.1.8 and 10.1.11 (2017: 10.1), Propositions 10.1.9 and 10.1.10 (2017: 10.4)

Also formalized. The full subcategory $\mathcal{EP}_{lreg}$ of p. 461 (G.111) is §X.27. Remark 10.1.8 (new in the 2021 edition), with the example of Appendix §10.6.3 on its weighted Sobolev sc-retract (G.112), is §X.28. Propositions 10.1.9 and 10.1.10 (G.113, G.114) are the next two paragraphs.

Proposition 10.1.9 (V10.62) `Chapter10/EquivalenceLR · EpFunctor.proposition_10_1_9`, for (LR) as in Definition 7.4.19 `Chapter7/Zhou · EpGroupoid.IsLR`. *The transport chart* `Chapter10/EquivalenceLR · EpFunctor.TransportChart` `Chapter10/EquivalenceLR · EpFunctor.exists_transportChart`: for $\psi : F(x) \to y$, $Q = \widehat{\psi} \circ F$ with $\widehat{\psi} = t \circ (s|\mathbf{U}(\psi))^{-1}$ is an sc-diffeomorphism of a neighbourhood of x onto one of y, with morphisms $\psi_u : F(u) \to Q(u)$. *The isomorphism* $g \mapsto \psi \circ F(g) \circ \psi^{-1}$, $G_x \to G_y$ `Chapter10/EquivalenceLR · EpFunctor.TransportChart.conj` `Chapter10/EquivalenceLR · EpFunctor.TransportChart.bijective_conj`; on p. 469 its second factor $\sigma \mapsto \psi \circ \sigma \circ \psi^{-1}$ is printed with target $U(y)$, read G_y (possible misprint). The equivariance (10.2)–(10.3), $Q(g * z) = (\psi \circ F(g) \circ \psi^{-1}) * Q(z)$ `Chapter10/EquivalenceLR · EpFunctor.TransportChart.Q_Φ`, comes from the uniqueness of Γ on connected sets `Chapter10/EquivalenceLR · EpGroupoid.NaturalRep.eqOn_Γ`. *The step the text takes for granted,* $U(y) = Q(U(x))$ "with the natural action": a natural representation at y (Theorem 7.1.13) restricted to $Q(U(x))$ is one, invariant under G_y by the equivariance and the surjectivity of the isomorphism `Chapter10/EquivalenceLR · EpFunctor.TransportChart.exists_naturalRep_push`; the converse direction restricts one at x to $Q^{-1}(U(y))$ `Chapter10/EquivalenceLR · EpFunctor.TransportChart.exists_naturalRep_pull` `Chapter10/EquivalenceLR · EpGroupoid.NaturalRep.eqOn_Φ`. *The conjugation.* The condition of (LR) on one $U(x)$ `Chapter10/EquivalenceLR · EpGroupoid.NaturalRep.HasLR` `Chapter10/EquivalenceLR · EpGroupoid.isLR_iff_hasLR` passes both ways along an equivariant sc-diffeomorphism over a surjection of the groups: $\beta = Q^{-1} \circ \gamma \circ Q = \hat{g}$ gives $\gamma = (\psi \circ F(g) \circ \psi^{-1})^\wedge$ `Chapter10/EquivalenceLR · EpGroupoid.NaturalRep.hasLR_iff_of_equivariant`. *Witness* `Chapter10/EquivalenceLR · EquivalenceLRExamples.nonempty_transportChart_pointEP`.

Proposition 10.1.10 (2017: 10.4) (V10.63) `Chapter10/EquivalenceLR · EpFunctor.proposition_10_1_10_one` `Chapter10/EquivalenceLR · EpFunctor.proposition_10_1_10_one_of_isLR_right` `Chapter10/EquivalenceLR · EpFunctor.`

proposition_10_1_10_two. (1) As in the text: $\beta = G^{-1} \circ \hat{\psi} \circ F$ of (10.4) is an sc-diffeomorphism near x with $|\beta(z)| = |z|$, (LR) for X gives $\beta = \hat{g}$, and $\alpha_z = G(\Gamma(g,z))^{-1} \circ \psi_z$. Only (LR) for X is used; with (LR) for Y, Proposition 10.1.9 supplies it. (2) Differentiating α, $T\alpha(v)$ is a morphism $TF(v) \to TG(v)$, so $|TF| = |TG|$. *Witness* Chapter10/EquivalenceLR · EquivalenceLRExamples.proposition_10_1_10_hypotheses. The families are in general not natural (§X.20).

Remark 10.1.11 (2017: 10.1) (V10.8) Chapter10/EquivalenceExamples · EpGroupoid.Examples.remark_10_1_11. The ep-groupoid is $\mathbb{Z}/2$ acting on $\mathbb{R}^2$ by $z \mapsto -z$ Chapter10/EquivalenceExamples · EpGroupoid.Examples.pointReflectionEpGroupoid, sc-smooth by Chapter10/EquivalenceExamples · EpGroupoid.Examples.isScSmoothMap_units_smul_rn; $G = -\mathrm{id}$ Chapter10/EquivalenceExamples · EpGroupoid.Examples.negFunctor is an equivalence Chapter10/EquivalenceExamples · EpGroupoid.Examples.isEquivalence_negFunctor with $|\mathrm{id}| = |G|$ Chapter10/EquivalenceExamples · EpGroupoid.Examples.orbitMap_id_eq_negFunctor. *Step 1.* $\alpha_z = (-1, z)$ is an sc-smooth family $F(z) \to G(z)$ Chapter10/EquivalenceExamples · EpGroupoid.Examples.remark_10_1_11_family: the conclusion of Proposition 10.1.10 (1) holds in the example. *Step 2.* A family with $\alpha_0 = 1_0$ and $\alpha_z : z \to -z$ near 0 must take the value $(-1, z)$ at every $z \neq 0$, because the only morphism $z \to -z$ is the group element -1 Chapter10/EquivalenceExamples · EpGroupoid.Examples.rn_eq_zero_of_eq_neg Chapter10/EquivalenceExamples · EpGroupoid.Examples.not_eventually_eq_neg; continuity at 0 fails. Hence no sc-smooth family exists either Chapter10/EquivalenceExamples · EpGroupoid.Examples.remark_10_1_11_scSmooth.

X.6 Remark 10.1.12, Propositions 10.1.13 and 10.1.14 (2017: 10.5), Example 10.1.15 (2017: 10.1)

Remark 10.1.12 (V10.9) Chapter10/EquivalenceReduced · EpFunctor.IsEquivalence.remark_10_1_12. *Step 1.* $g \mapsto F(g)$ is a homomorphism $G_x \to G_{F(x)}$ Chapter10/EquivalenceReduced · EpFunctor.isotropyHom Chapter10/EquivalenceReduced · EpFunctor.isotropyHom_val, bijective for an equivalence (fullness and faithfulness at (x,x)) Chapter10/EquivalenceReduced · EpFunctor.IsEquivalence.bijective_isotropyHom. *Step 2.* $g \in T_x$ iff $F(g) \in T_{F(x)}$ Chapter10/EquivalenceReduced · EpFunctor.isotropyHom_mem_trivialSet_iff, since F is a local sc-diffeomorphism on objects and on morphisms, and the local actions correspond. *Step 3.* Conjugation by $\psi : F(x) \to y$ Chapter7/Groupoid · GroupoidStr.isotropyConj maps $T_{F(x)}$ onto T_y Chapter7/Effective · EpGroupoid.isotropyConj_mem_trivialSet_iff. The text's $G_x \to Y_y$ is read $G_x \to G_y$ (possible misprint).

Proposition 10.1.13 (V10.10) Chapter10/EquivalenceReduced · EpFunctor.proposition_10_1_13. *Step 1,* $\mathbf{X}^T$ *along* F. For a local sc-diffeomorphism on objects, $\varphi \in \mathbf{X}^T$ iff $F(\varphi) \in \mathbf{Y}^T$ Chapter10/EquivalenceReduced · EpFunctor.mor_mem_nonEffectivePart Chapter10/EquivalenceReduced · EpFunctor.mem_nonEffectivePart_of_mor, that is $\mathbf{X}^T = F^{-1}(\mathbf{Y}^T) \cap \{s = t\}$ Chapter10/EquivalenceReduced · EpFunctor.nonEffectivePart_eq. *Step 2, (1).* So F_R is well defined Chapter10/EquivalenceReduced · EpFunctor.reducedMap Chapter10/EquivalenceReduced · EpFunctor.reducedMap_π, continuous Chapter10/EquivalenceReduced · EpFunctor.continuous_reducedMap and open, F being open on morphisms and the quotient maps open Chapter10/EquivalenceReduced · EpFunctor.isOpenMap_reducedMap; only the local sc-diffeomorphism property of F is used. *Step 3, closedness.* For an equivalence, $\mathbf{X}^T$ is closed iff $\mathbf{Y}^T$ is Chapter10/EquivalenceReduced · EpFunctor.IsEquivalence.isClosed_nonEffectivePart_iff. From Y to X: $\mathbf{X}^T$ is the preimage of a closed set intersected with a closed set. From X to Y: a $\psi \in \mathrm{cl}(\mathbf{Y}^T)$ at y is conjugated, by a local inverse of t at a morphism $\sigma : F(x) \to y$, into a morphism at $F(x)$ in $\mathrm{cl}(F(\mathbf{X}^T))$, with the continuity of the composition at a point Chapter10/EquivalenceReduced · EpGroupoid.continuousAt_comp; closures replace the text's sequences. *Step 4, (2).* Theorem 7.2.22 says $\mathbf{X}^R$ is Hausdorff iff $\mathbf{X}^T$ is closed Chapter7/ReducedCriterion · EpGroupoid.theorem_7_2_22; with Step 3 this gives (2), the route of the text.

Proposition 10.1.14 (2017: 10.5) (V10.11) Chapter10/EquivalenceReduced · EpFunctor.proposition_10_1_14. With

both reduced morphism spaces Hausdorff the reduced ep-groupoids of Chapter 7 exist Chapter7/Reduced · EpGroupoid.reducedEpGroupoid. F_R is F on objects and F_R of Step 2 on morphisms Chapter10/EquivalenceReduced · EpFunctor.reducedGroupoidFunctor Chapter10/EquivalenceReduced · EpFunctor.reduced; it is a functor since $[\cdot]$ is Chapter10/EquivalenceReduced · EpFunctor.reducedπ_eq_of_mor, sc-smooth since the M-polyfold structure of $\mathbf{X}^R$ is the one for which the quotient map is a local sc-diffeomorphism, full and faithful by Remark 10.1.12, and $|F_R| = |F|$. By Proposition 10.1.13 (2) either Hausdorff hypothesis implies the other; both are kept, as in the text.

Example 10.1.15 (2017: 10.1) (V10.12) Chapter10/EquivalenceExamples · EpGroupoid.Examples.example_10_1_15. $X = \mathbb{Z}/4 \ltimes \mathbb{R}$ with $1, 3$ acting by -1 Chapter10/EquivalenceExamples · EpGroupoid.Examples.z4LineAction Chapter10/EquivalenceExamples · EpGroupoid.Examples.example1015X, $Y = \mathbb{Z}/4 \ltimes \mathbb{R}^2$ by quarter turns Chapter10/EquivalenceExamples · EpGroupoid.Examples.z4PlaneAction Chapter10/EquivalenceExamples · EpGroupoid.Examples.example1015Y, Φ to the origin Chapter10/EquivalenceExamples · EpGroupoid.Examples.example1015Functor. *Step 1.* 2 acts trivially on $\mathbb{R}$, not on $\mathbb{R}^2$ Chapter10/EquivalenceExamples · EpGroupoid.Examples.example1015X_two_mem_nonEffectivePart Chapter10/EquivalenceExamples · EpGroupoid.Examples.example1015Y_two_not_mem_nonEffectivePart. *Step 2.* Hence $(1, x)$ and $(3, x) = (2, x) \circ (1, x)$ have the same class Chapter10/EquivalenceExamples · EpGroupoid.Examples.example1015X_reducedπ_one_eq_three, their images not Chapter10/EquivalenceExamples · EpGroupoid.Examples.example1015Y_reducedπ_one_ne_three, so no map of sets f with $f([\varphi]) = [\Phi(\varphi)]$ exists. The text speaks of an induced map of the reduced ep-groupoids; the statement here needs no topology.

X.7 Propositions 10.1.16–10.1.19: (LUC), (ZHOU), (SLUC), (SLR)

Proposition 10.1.16 (V10.13) Chapter10/EquivalenceReduced · EpFunctor.proposition_10_1_16. (LUC) Chapter7/ReducedCriterion · EpGroupoid.IsLUC is the closedness of $\mathbf{X}^T$ (Proposition 7.2.21, part of Theorem 7.2.22) Chapter7/ReducedCriterion · EpGroupoid.proposition_7_2_21, and the closedness passes along equivalences (§X.6, Step 3). The text cites Theorem 7.2.22 here and in Proposition 10.1.13; the citation is the theorem on p. 323.

Proposition 10.1.17 (V10.14) Chapter10/EquivalenceZhou · EpFunctor.proposition_10_1_17. *Step 1, smooth points.* x is smooth iff $F(x)$ is, and iff a $y \cong F(x)$ is Chapter10/EquivalenceZhou · EpGroupoid.mem_smoothSet_src_iff Chapter10/EquivalenceZhou · EpGroupoid.mem_smoothSet_tgt_iff. *Step 2, Y to X.* For $g \in G_x$ with $Tg = \mathrm{id}$ on T_xX: $T(F(g)) \circ TF = TF \circ Tg$ Chapter10/EquivalenceZhou · EpFunctor.tangentMor_mor and TF is onto $T_{F(x)}Y$, so $T(F(g)) = \mathrm{id}$, $F(g) \in T_{F(x)}$ by (ZHOU) for Y, and $g \in T_x$ by Remark 10.1.12 Chapter10/EquivalenceZhou · EpFunctor.IsEquivalence.isZhou_of_isZhou_right. *Step 3, X to Y.* For $k \in G'_y$ with $Tk = \mathrm{id}$ and $\psi : F(x) \to y$, $k' = \psi^{-1}k\psi \in G'_{F(x)}$ has $Tk' = \mathrm{id}$ by the composition rule for T Chapter8/TangentEp · EpGroupoid.tangentMor_comp; $k' = F(g)$ with $g \in G_x$ (Remark 10.1.12), $Tg = \mathrm{id}$ by the injectivity of TF on T_xX, so $g \in T_x$, $k' \in T_{F(x)}$ and $k \in T_y$ Chapter10/EquivalenceZhou · EpFunctor.IsEquivalence.isZhou_of_isZhou. The text argues with natural representations instead; it writes $U(F(y))$ and "$x \in U(x)$" in (b), read $U(F(x))$ and $a \in U(x)$ (possible misprints).

Proposition 10.1.18 (V10.15) Chapter10/EquivalenceReduced · EP.proposition_10_1_18. *Step 1.* The restriction of F to level 1 is an sc-smooth functor $X^1 \to Y^1$ Chapter10/EquivalenceReduced · EpFunctor.liftOne, an equivalence when F is Chapter10/EquivalenceReduced · EpFunctor.IsEquivalence.liftOne (orbit spaces of X^1 carry the level-1 topology, and $|F^1|$ is a homeomorphism by Lemma 10.1.2 again). *Step 2.* By induction, every $X^i \to Y^i$ Chapter10/EquivalenceReduced · EP.exists_isEquivalence_lift over Chapter 7's lifts Chapter7/Zhou · EP.lift. *Step 3.* Proposition 10.1.16 at each level. The text cites Proposition 10.1.9 at Step 3; we read Propo-

sition 10.1.16 (possible misprint).

Proposition 10.1.19 (V10.16) `Chapter10/EquivalenceLR · EP.proposition_10_1_19` `Chapter10/EquivalenceZhou · EP.isSLR_iff_of_isLR_iff`. Steps 1–2 as above, then Proposition 10.1.9 at each level (§X.5). The reduction alone holds when the two ep-groupoids agree `Chapter10/EquivalenceZhou · EP.isLR_iff_lift_self`; G.115 is closed.

X.8 Definition 10.2.1 (2017: 10.3): the weak fibred product

Definition 10.2.1 (2017: 10.3) (V10.17) `Chapter10/WeakFibredProduct · WeakFibredProduct.groupoid`. *Objects.* $\{(\phi, z) \mid t(\phi) = G(z)\} \subseteq \mathbf{Y} \times Z$ `Chapter10/WeakFibredProduct · WeakFibredProduct.objRight`, then $\{(x, (\phi, z)) \mid F(x) = s(\phi)\}$ `Chapter10/WeakFibredProduct · WeakFibredProduct.objSet` `Chapter10/WeakFibredProduct · WeakFibredProduct.Obj`, with projections and extensionality `Chapter10/WeakFibredProduct · WeakFibredProduct.Obj.ext`. *Morphisms.* The same with $\mathbf{X}$, $\mathbf{Z}$ and $F \circ s$, $G \circ s$ `Chapter10/WeakFibredProduct · WeakFibredProduct.morRight` `Chapter10/WeakFibredProduct · WeakFibredProduct.morSet` `Chapter10/WeakFibredProduct · WeakFibredProduct.Mor` `Chapter10/WeakFibredProduct · WeakFibredProduct.Mor.ext`. *Structure maps.* The conjugate $G(k) \circ \phi \circ F(h)^{-1}$ `Chapter10/WeakFibredProduct · WeakFibredProduct.conj` has the ends $F(t(h))$, $G(t(k))$ `Chapter10/WeakFibredProduct · WeakFibredProduct.src_conj` `Chapter10/WeakFibredProduct · WeakFibredProduct.tgt_conj`; it is the target's middle entry `Chapter10/WeakFibredProduct · WeakFibredProduct.tgt`, s keeps ϕ `Chapter10/WeakFibredProduct · WeakFibredProduct.src`, the unit is $(1_x, \phi, 1_z)$ `Chapter10/WeakFibredProduct · WeakFibredProduct.unit` and the inverse $(h^{-1}, \mathrm{conj}, k^{-1})$ `Chapter10/WeakFibredProduct · WeakFibredProduct.inv`. The text prints $\iota(h, \psi, k) = (h^{-1}, G(k) \circ \phi \circ F(h)^{-1}, k^{-1})$; we read $\psi = \phi$ (possible misprint). The product of a composable pair is $(h \circ h', \phi', k \circ k')$ `Chapter10/WeakFibredProduct · WeakFibredProduct.compOf`, extended to a total map that returns its first argument off composable pairs `Chapter10/WeakFibredProduct · WeakFibredProduct.comp`. *Groupoid laws.* By the rules $\mathrm{conj}(h \circ h', \phi', k \circ k') = \mathrm{conj}(h, \mathrm{conj}(h', \phi', k'), k)$ `Chapter10/WeakFibredProduct · WeakFibredProduct.conj_comp`, conj of units `Chapter10/WeakFibredProduct · WeakFibredProduct.conj_unit` and of inverses `Chapter10/WeakFibredProduct · WeakFibredProduct.conj_inv`, with ϕ recovered from the target `Chapter10/WeakFibredProduct · WeakFibredProduct.conj_recover` `Chapter10/WeakFibredProduct · WeakFibredProduct.conj_comp_mor`; a morphism is a loop iff its ends agree `Chapter10/WeakFibredProduct · WeakFibredProduct.src_eq_tgt_iff`.

X.9 Theorem 10.2.2 (2017: 10.2): $X \times_Y Z$ is an ep-groupoid

The admissibility `Chapter10/WeakFibredProduct · WeakFibredProduct.Admissible`. The construction uses of F (or of G) only that it is a local sc-diffeomorphism on objects, which every equivalence is `Chapter10/WeakFibredProductTheorem · WeakFibredProduct.Admissible.of_isEquivalence_left` `Chapter10/WeakFibredProductTheorem · WeakFibredProduct.Admissible.of_isEquivalence_right`. *Step 1, sub-M-polyfolds.* Part I's fibred product of an sc-smooth map with a local sc-diffeomorphism is a sub-M-polyfold (Proposition 2.5.20); $t : \mathbf{Y} \to Y$ is one, so $\mathbf{Y}_t \times_G Z$ is a sub-M-polyfold of $\mathbf{Y} \times Z$ `Chapter10/WeakFibredProduct · WeakFibredProduct.isSubMPolyfold_objRight` `Chapter10/WeakFibredProduct · WeakFibredProduct.PA`, and its projection to Z is a local sc-diffeomorphism `Chapter10/WeakFibredProduct · MPolyfold.isLocalScDiffeo_snd_fibredProduct`; then the second fibred product with F or with that projection `Chapter10/WeakFibredProduct · WeakFibredProduct.isSubMPolyfold_objSet` `Chapter10/WeakFibredProduct · WeakFibredProduct.PObj`, and the same for morphisms `Chapter10/WeakFibredProduct · WeakFibredProduct.isSubMPolyfold_morRight` `Chapter10/WeakFibredProduct · WeakFibredProduct.isSubMPolyfold_morSet` `Chapter10/WeakFibredProduct · WeakFibredProduct.PB` `Chapter10/WeakFibredProduct · WeakFibredProduct.PMor`. The text says the sets are sub-M-polyfolds of

the triple products. They are, and the iterated structures are the induced ones (§X.29; G.116); the construction here does not use it. *Step 2, the projections.* x, ϕ, z, h, ϕ, k are sc-smooth Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_x Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_z Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_k, and a map into $X \times_Y Z$ is sc-smooth when its entries are Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothOn_obj_of Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothOn_mor_of. For F admissible, $(x, \phi, z) \mapsto z$ and $(h, \phi, k) \mapsto k$ are local sc-diffeomorphisms ((10.9), (10.10)) Chapter10/WeakFibredProduct · WeakFibredProduct.isLocalScDiffeo_z Chapter10/WeakFibredProduct · WeakFibredProduct.isLocalScDiffeo_k; for G admissible the projections to X and $\mathbf{X}$ are Chapter10/WeakFibredProduct · WeakFibredProduct.isLocalScDiffeo_x Chapter10/WeakFibredProduct · WeakFibredProduct.isLocalScDiffeo_h Chapter10/WeakFibredProduct · MPolyfold.isLocalScDiffeo_fst_fibredProduct. *Step 3, s and t.* $\pi_Z \circ s = s_Z \circ \pi_{\mathbf{Z}}$ and $\pi_Z \circ t = t_Z \circ \pi_{\mathbf{Z}}$ with three local sc-diffeomorphisms make s, t ones Chapter10/WeakFibredProduct · MPolyfold.IsLocalScDiffeo.of_comm Chapter10/WeakFibredProduct · WeakFibredProduct.isLocalScDiffeo_src Chapter10/WeakFibredProduct · WeakFibredProduct.isLocalScDiffeo_tgt; their sc-smoothness uses that of the conjugate Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_conj Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_src Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_tgt. *Step 4, unit, inverse, multiplication* Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_unit Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothMap_inv Chapter10/WeakFibredProduct · WeakFibredProduct.isScSmoothComp: entries are multiplications of X and Z and projections, sc-smooth on the composable pairs Chapter10/WeakFibredProduct · EpGroupoid.isScSmoothOn_comp_of. *Step 5, properness.* For open $U \ni x$, $V \ni z$ with the properness property in X and Z, $W = \{x' \in U, z' \in V\}$ has t proper on $s^{-1}(\mathrm{cl}\, W)$ Chapter10/WeakFibredProduct · WeakFibredProduct.exists_isProperMap: subsequences of h_n, then of k_n, converge, and $\phi_n = G(k_n)^{-1} \circ (G(k_n) \circ \phi_n \circ F(h_n)^{-1}) \circ F(h_n)$ converges by continuity of the multiplication Chapter10/WeakFibredProduct · EpGroupoid.tendsto_comp Chapter10/WeakFibredProduct · WeakFibredProduct.continuous_conj. The text writes $t : s^{-1}(U) \to X$; Definition 7.1.3 (3) asks for the closure, which is the reading. No admissibility is needed here. *Conclusion* (V10.18) Chapter10/WeakFibredProduct · WeakFibredProduct.epGroupoid.

X.10 Theorem 10.2.2 (2017: 10.2): the projections, and Remark 10.2.3 (2017: 10.2)

The functors Chapter10/WeakFibredProductTheorem · WeakFibredProduct.projLeft Chapter10/WeakFibredProductTheorem · WeakFibredProduct.projRight Chapter10/WeakFibredProductTheorem · WeakFibredProduct.projLeft_obj. $\sigma(x, \phi, z) = \phi$ is a natural transformation $F \circ \pi_X \to G \circ \pi_Z$ Chapter10/WeakFibredProductTheorem · WeakFibredProduct.natTrans Chapter10/WeakFibredProductTheorem · WeakFibredProduct.natTrans_app: its naturality is the definition of the target, and it is sc-smooth as a projection. Hence $F \circ \pi_X \simeq G \circ \pi_Z$ whenever $X \times_Y Z$ is defined Chapter10/WeakFibredProductTheorem · WeakFibredProduct.naturallyEquivalent.

F an equivalence (V10.19) Chapter10/WeakFibredProductTheorem · WeakFibredProduct.isEquivalence_projRight. *Step 1, faithful.* A morphism over k is (h, ϕ, k) with $F(h)$ determined by k and the ends, and F is faithful. *Step 2, full.* For $k : z \to z'$ between (x, ϕ, z) and (x', ϕ', z'), $\phi'^{-1} \circ G(k) \circ \phi : F(x) \to F(x')$ is $F(h_0)$ by fullness of F, and (h_0, ϕ, k) lies over k. The text writes the composite as $\phi' \circ G(k) \circ \phi^{-1}$, which does not compose; we read $\phi'^{-1} \circ G(k) \circ \phi$ (possible misprint). *Step 3, essentially surjective.* $G(z)$ receives $\psi : F(x) \to G(z)$ Chapter10/Equivalence · EpFunctor.IsEquivalence.exists_iso, and (x, ψ, z) lies over z. *Step 4.* Lemma 10.1.2 with Step 2 of §X.9. *The rest of the theorem* Chapter10/WeakFibredProductTheorem · WeakFibredProduct.theorem_10_2_2: an equivalence preserves the degeneracy

index Chapter10/WeakFibredProductTheorem · EpFunctor.IsEquivalence.degIndex_obj, so $d(x,\phi,z) = d_Z(z)$ Chapter10/WeakFibredProductTheorem · WeakFibredProduct.degIndex_eq_z, and pulls back tameness Chapter10/WeakFibredProductTheorem · EpFunctor.IsEquivalence.isTame_of_isTame and the paracompactness of the orbit space, through $|\pi_Z|$ Chapter10/WeakFibredProductTheorem · EpFunctor.IsEquivalence.hasParacompactOrbitSpace. *Witness.* $\mathbb{Z} \to$ pt and $\mathrm{id}_{\mathrm{pt}}$ Chapter10/WeakFibredProductTheorem · WeakFibredProduct.Examples.theorem_10_2_2_pairToPoint.

G an equivalence, and both (V10.20) Chapter10/WeakFibredProductTheorem · WeakFibredProduct.isEquivalence_projLeft Chapter10/WeakFibredProductTheorem · WeakFibredProduct.degIndex_eq_x Chapter10/WeakFibredProductTheorem · WeakFibredProduct.theorem_10_2_2_right Chapter10/WeakFibredProductTheorem · WeakFibredProduct.theorem_10_2_2_both. The symmetric argument with ϕ^{-1}. The admissibility is a proposition, so the ep-groupoids built from F and from G coincide and the two cases combine.

Remark 10.2.3 (2017: 10.2) (V10.21) Chapter10/WeakFibredProductTheorem · WeakFibredProduct.remark_10_2_3. Both projections are equivalences and $\tau = \sigma$ is natural. *Witness.* id and $-\mathrm{id}$ on $\mathbb{Z}/2 \ltimes \mathbb{R}^2$ Chapter10/WeakFibredProductTheorem · WeakFibredProduct.Examples.remark_10_2_3_negFunctor. The sentences on "smaller models" have no formal content.

X.11 Definition 10.4.1 (2017: 10.10): strong bundle equivalences

The orbit space at level $[1]$ Chapter10/StrongBundleEquivalence · EpStrongBundle.oneOrbitSetoid Chapter10/StrongBundleEquivalence · EpStrongBundle.OneOrbitSpace Chapter10/StrongBundleEquivalence · EpStrongBundle.oneOrbitMap. $W[1]$ is not built as an ep-groupoid; $|W[1]|$ is the quotient of $W_{0,1}$ with its level-1 topology by the orbit relation of W, and a strong bundle functor induces a continuous map of these quotients Chapter10/StrongBundleEquivalence · EpStrongBundle.continuous_oneOrbitMap.

Definition 10.4.1 (2017: 10.10) (V10.22) Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence. A strong bundle functor Chapter8/EpStrongBundle · EpStrongBundle.IsStrongBundleFunctor with ϕ an equivalence, Φ an equivalence at level $[0]$, $|\Phi|$ a homeomorphism of $|W[1]|$, and local strong bundle isomorphisms on objects and morphisms Chapter8/EpStrongBundle · StrongBundle.IsStrongBundleIsoOn. Clause (1) at level $[1]$ is read in this form: fullness and faithfulness at $[1]$ are those at $[0]$ restricted, and the local sc-diffeomorphism property at $[1]$ follows from (2) Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isLocalScDiffeo_one Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isLocalScDiffeo_obj. *Consequences.* $P' \circ \Phi = \phi \circ P$ Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.covers; $\Phi_x : W_x \to W'_{\phi(x)}$ is a linear isomorphism, the local strong bundle isomorphism at x restricted Chapter10/StrongBundleEquivalence · StrongBundle.IsStrongBundleIsoOn.P_inv Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.fiberEquiv, so Φ is injective on fibres Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.eq_of_obj_eq. *Class.* The identity Chapter10/StrongBundleEquivalence · EpStrongBundle.isStrongBundleEquivalence_id; composites Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.comp, with strong bundle functors Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleFunctor.comp and local strong bundle isomorphisms composing on open sets Chapter10/StrongBundleEquivalence · StrongBundle.IsStrongBundleIsoOn.restrict Chapter10/StrongBundleEquivalence · StrongBundle.IsStrongBundleIsoOn.comp Chapter10/StrongBundleEquivalence · StrongBundle.IsStrongBundleIsoOn.exists_comp; isomorphisms with an inverse strong bundle functor Chapter10/StrongBundleEquivalenceNat · StrongBundle.isStrongBundleIsoOn_

univ_of_inverse Chapter10/StrongBundleEquivalenceNat · EpFunctor.isEquivalence_of_inverse Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.isStrongBundleEquivalence_of_inverse. *Witness.* Over $-\mathrm{id}$ of $\mathbb{R}^n$ Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.negMap, the projection of the pull-back of the trivial bundle Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.negBundle Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.negEpBundle, with inverse Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.negInv Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.isStrongBundleMap_negInv, is a strong bundle equivalence Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.isStrongBundleEquivalence_pullbackProj' not over the identity Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExa trivialNeg_obj_ne_id.

X.12 The pull-back and the push-forward, (10.15)–(10.17) and (10.22)

Pull-back (V10.23) Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pullback. $\Phi^* f'(x)$ is the unique $w \in W_x$ with $\Phi(w) = f'(\phi(x))$ Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.obj_pullback Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pullback_eq, a section Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.P_pullback Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isSection_pullback, functorial when f' is Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isFunctorialSection_pullback ((10.17), by the injectivity of Φ on fibres and of $\mu'(\sigma, \cdot)$ Chapter10/StrongBundleEquivalence · EpStrongBundle.μ_injective_snd).

Push-forward Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.preObj Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.preMor Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pushforward Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pushforward_def. For x' choose x and $\sigma : \phi(x) \to x'$ (essential surjectivity of ϕ) and set $\Phi_* f(x') = \mu'(\sigma, \Phi(f(x)))$, a section Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.P_pushforward Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isSection_pushforward. *(10.22).* For a section functor f and any y, $\sigma' : \phi(y) \to x'$, the value is $\mu'(\sigma', \Phi(f(y)))$ Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pushforward_eq: $\sigma'^{-1} \circ \sigma : \phi(x) \to \phi(y)$ is $\phi(\tau)$ by fullness, $f(y) = \mu(\tau, f(x))$ by functoriality, and Φ intertwines μ and μ' Chapter10/StrongBundleEquivalence · EpStrongBundle.μ_mk_congr. Hence $\Phi_* f$ is a section functor Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isFunctorialSection_pushforward, and $\Phi^* \Phi_* f = f$, $\Phi_* \Phi^* f' = f'$ Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pullback_pushforward Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pushforward_pullback.

(10.15) Chapter10/StrongBundleEquivalence · EpStrongBundle.exists_μ_eq_of_orbitMap_eq Chapter10/StrongBundleEquivalence · EpStrongBundle.orbitMap_eq_of_forall_exists. $|\Phi| = |\Psi|$ iff every $\Psi(w)$ is $\mu'(\sigma, \Phi(w))$ for some σ.

X.13 Propositions 10.4.2–10.4.4 (2017: 10.7–10.9)

Proposition 10.4.2 (2017: 10.7) (V10.24) `Chapter10/StrongBundleEquivalence · EpStrongBundle.proposition_10_4_2` `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pullback_eq_of_orbitMap_eq`. With $g = \Psi^* f'$, (10.15) gives $\sigma : \phi(x) \to \psi(x)$ with $\mu'(\sigma, \Phi(g(x))) = \Psi(g(x)) = f'(\psi(x))$; functoriality of f' gives $f'(\psi(x)) = \mu'(\sigma, f'(\phi(x))) = \mu'(\sigma, \Phi(\Phi^* f'(x)))$; the injectivity of $\mu'(\sigma, \cdot)$ and of Φ_x gives $g(x) = \Phi^* f'(x)$. sc-smoothness is not used. The text's "$f' : W' \to X'$" is read $f' : X' \to W'$ (possible misprint).

Proposition 10.4.3 (2017: 10.8) (V10.25) `Chapter10/StrongBundleEquivalence · EpStrongBundle.proposition_10_4_3` `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.pushforward_eq_of_orbitMap_eq`. With $\sigma : \phi(x) \to \psi(x)$ from (10.15) at $f(x)$, and (10.22) for Ψ applied to the composite of σ^{-1} with the choice for Φ.

Proposition 10.4.4 (2017: 10.9) (V10.26) `Chapter10/StrongBundleEquivalence · EpStrongBundle.proposition_10_4_4`. The pull-back identity pointwise from the uniqueness in the definition; the push-forward identity from (10.22) for $\Psi \circ \Phi$.

X.14 Theorem 10.4.5 (2017: 10.8)

Theorem 10.4.5 (2017: 10.8) (V10.27) `Chapter10/StrongBundleEquivalence · EpStrongBundle.theorem_10_4_5`. *Step 1, pull-back.* Near x_0, $\Phi^* f'$ agrees with $\Phi_U^{-1} \circ f' \circ \phi$ for the local strong bundle isomorphism Φ_U `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.eqOn_pullback`, so it is sc-smooth `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScSmoothSection_pullback` and sc^+ when f' is `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScPlusSection_pullback`, smoothness being a local property in charts `Chapter10/StrongBundleEquivalence · MPolyfold.isScSmoothOn_of_forall_charts`. *Step 2, push-forward.* The text says the sc-smoothness is easily verified. Near x_0', with a local inverse τ of t' at the chosen $\sigma_0 : \phi(y_0) \to x_0'$ and a local inverse g_1 of ϕ at y_0, (10.22) gives $\Phi_* f = \mu' \circ (\tau, \Phi \circ f \circ g_1 \circ s' \circ \tau)$ `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.exists_pushforward_local`, sc-smooth `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScSmoothSection_pushforward`. At level $[1]$ the pair is sc-smooth into the pull-back's level $[1]$ by its universal property on an open set `Chapter10/StrongBundleEquivalence · StrongBundle.isScSmoothOn_to_pullback_one`, so sc^+ is preserved `Chapter10/StrongBundleEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScPlusSection_pushforward`. *Step 3.* With §X.12 and §X.13, bijections between Chapter 8's sets of section functors `Chapter8/EpStrongBundle · EpStrongBundle.sectionFunctors` `Chapter8/EpStrongBundle · EpStrongBundle.plusSectionFunctors`, independent of Φ within $|\Phi|$. The text's second display, $\Phi^* : \Gamma(P', \mu') \to \Gamma(P, \mu)$ in the Γ^+ line, is read with Γ^+ (a reading point). *The sc-Fredholm part* (G.121) is §X.31 `Chapter10/FredholmEquivalence · EpStrongBundle.theorem_10_4_5_fred`, and the bijections are linear isomorphisms there too. *Witness* `Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.bijOn_pushforward_example`.

X.15 Definitions 10.4.8, 10.4.10 and 10.4.11, Remark 10.4.9 (2017: 10.11–10.13, 10.4)

Definition 10.4.8 (2017: 10.11) (V10.28) `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans` `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatEquiv`. T is data with $T(w) : \Phi(w) \to \Psi(w)$ `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.mem` and naturality, over an `EpNatTrans` τ. Reflexivity `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.refl`; a witness with $\Phi \neq \Psi$ `Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.strongBundleNatEquiv_example`.

Remark 10.4.9 (2017: 10.4) (V10.29). *Step 1.* A morphism of $\mathbf{W}'$ is (σ, w') with $\sigma \in \mathbf{X}'$; $T(w)$ lies over $\tau(P(w))$ and starts at $\Phi(w)$, so $T(w) = (\tau(P(w)), \Phi(w))$ `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.T_val` `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.T_eq` and $\Psi(w) = \mu'(\tau(P(w)), \Phi(w))$ `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.obj_eq`. The text prints the second line of (10.23) with μ; we read μ'. *Step 2.* T and Ψ on objects are determined by Φ and τ `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.unique`, and Ψ on morphisms too, if Ψ is a strong bundle functor `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.unique_functor`. *Step 3.* T is a strong bundle map covering τ `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.isStrongBundleMap_T`.

Definition 10.4.10 (2017: 10.12) (V10.30) `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.IsStrongBundleNatTransMap`. Definition 10.4.8 gives it by Remark 10.4.9 `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.isStrongBundleNatTransMap`; conversely the naturality of T follows from (10.23) and the functoriality of Φ, Ψ `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.IsStrongBundleNatTransMap.toNatTrans`. $\Phi \simeq \Psi$ implies $|\Phi| = |\Psi|$ `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatTrans.orbitMap_eq` `Chapter10/StrongBundleEquivalenceNat · EpStrongBundle.StrongBundleNatEquiv.orbitMap_eq`.

Definition 10.4.11 (2017: 10.13) (V10.31) `Chapter10/StrongBundleEquivalenceNat · SEP` `Chapter10/StrongBundleEquivalenceNat · SEP.Hom` `Chapter10/StrongBundleEquivalenceNat · SEP.Hom.ext'`. A morphism is a pair (ϕ, Φ) with Φ a strong bundle functor covering ϕ; Φ alone determines ϕ only on the image of P. The strong bundle equivalences form a multiplicative class `Chapter10/StrongBundleEquivalenceNat · SEP.equivalences`, mapped into E by the forgetful functor `Chapter10/StrongBundleEquivalenceNat · SEP.toEP` `Chapter10/StrongBundleEquivalenceNat · SEP.toEP_map_mem_equivalences`. *Witness* `Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.negSEP` `Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.epSEP` `Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.negSEPHom` `Chapter10/StrongBundleEquivalenceExamples · StrongBundleEquivalenceExamples.negSEPHom_mem_equivalences`.

X.16 §10.3: (E1)–(E3), diagrams and their equivalence (Definitions 10.3.1, 10.3.3, 10.3.5, Lemmas 10.3.2, 10.3.4 (2017: Definitions 10.4–10.6, Lemmas 10.3, 10.4))

(E1)–(E3) (V10.32). (E1): an isomorphism of $\mathcal{EP}$ has an inverse sc-smooth functor, so it is full, faithful, a homeomorphism on orbit spaces and an sc-diffeomorphism on objects `Chapter10/`

LocalizationCategory · EPLocalization.isEquivalence_of_isIso. (E2) and (E3) are §X.1 and Proposition 10.1.5 Chapter10/Equivalence · EpFunctor.IsEquivalence.comp Chapter10/Equivalence · EpFunctor.proposition_10_1_5.

Diagrams (V10.33) Chapter10/Localization · EPLocalization.Diagram. The middle ep-groupoid is an object of $\mathcal{EP}$, so that a diagram, and later its class, lives one universe above the object and morphism types; no class-sized collection occurs. The weak fibred product of §X.9 is made an object of $\mathcal{EP}$ when admissible Chapter10/Localization · EPLocalization.wfp.

Definition 10.3.1 (2017: 10.4) Chapter10/Localization · EPLocalization.Diagram.IsRefinement Chapter10/Localization · EPLocalization.Diagram.IsRefinement.refl. Both examples after the definition: precomposition with an equivalence H Chapter10/Localization · EPLocalization.Diagram.precomp Chapter10/Localization · EPLocalization.Diagram.isRefinement_precomp, with H itself refining and the natural equivalences equalities Chapter10/Localization · EpFunctor.NaturallyEquivalent.of_eq; and naturally equivalent legs, with $H = 1_A$ Chapter10/Localization · EPLocalization.Diagram.isRefinement_of_naturallyEquivalent.

Lemma 10.3.2 (2017: 10.3) (V10.34) Chapter10/Localization · EPLocalization.Diagram.lemma_10_3_2 Chapter10/Localization · EPLocalization.Diagram.IsRefinement.trans. For $H : d' \to d$ and $H' : d'' \to d'$, $H \circ H'$ is an equivalence (§X.1) and $F \circ H \circ H' \simeq F' \circ H' \simeq F''$, by the compatibility of $\simeq$ with composition Chapter8/NatTrans · EpFunctor.NaturallyEquivalent.comp_right and its transitivity; the same for Φ.

Definition 10.3.3 (2017: 10.5) and Lemma 10.3.4 (2017: 10.4) (V10.35, V10.36) Chapter10/Localization · EPLocalization.Diagram.IsCommonRefinement Chapter10/Localization · EPLocalization.Diagram.lemma_10_3_4. *Step 1.* For W refining d by H and d' by H', and W' refining d' by K and d'' by K', H' and K are equivalences into A', so the weak fibred product $W \times_{A'} W'$ is defined and its projections are equivalences (Theorem 10.2.2). *Step 2.* The diagram (10.11) over $W \times_{A'} W'$ refines d by $H \circ \pi_W$; it refines d'' by $K' \circ \pi_{W'}$, because $F' \circ H' \circ \pi_W \simeq F' \circ K \circ \pi_{W'}$ by the natural transformation σ of the weak fibred product (§X.10) and Lemma 10.3.2. A refinement is equivalent to the refined diagram Chapter10/Localization · EPLocalization.Diagram.IsRefinement.equiv.

Definition 10.3.5 (2017: 10.6) (V10.37) Chapter10/Localization · EPLocalization.Diagram.Equiv Chapter10/Localization · EPLocalization.Diagram.setoid Chapter10/Localization · EPLocalization.Diagram.equiv_iff. Reflexivity and symmetry are immediate Chapter10/Localization · EPLocalization.Diagram.Equiv.refl Chapter10/Localization · EPLocalization.Diagram.Equiv.symm, transitivity is Lemma 10.3.4 Chapter10/Localization · EPLocalization.Diagram.Equiv.trans. *Witness.* pt $\leftarrow$ $\mathbb{Z}$-pair $\to$ pt, both legs the equivalence of §X.1, is equivalent to 1_{pt} through the refinement by that equivalence, which is not an isomorphism Chapter10/LocalizationCategory · EPLocalization.Examples.equiv_pairToPoint_id.

X.17 Lemma 10.3.6 (2017: 10.5), Definition 10.3.7 (2017: 10.7) and Theorem 10.3.8 (2017: 10.3) with Appendix §10.6.1

Lemma 10.3.6 (2017: 10.5) (V10.38) Chapter10/Localization · EPLocalization.Diagram.lemma_10_3_6. $|d| = |\Phi| \circ |F|^{-1}$, with $|F|^{-1}$ the inverse of the homeomorphism of Definition 10.1.1 (2) Chapter10/Localization · EPLocalization.Diagram.orbitMap Chapter10/Localization · EPLocalization.Diagram.continuous_orbitMap Chapter10/Localization · EPLocalization.Diagram.orbitMap_orbitMap_F Chapter10/Localization · EPLocalization.Diagram.orbitMap_eq_of. For $H : d' \to d$, $|F'| = |F \circ H| = |F| \circ |H|$ Chapter10/Localization · EpFunctor.orbitMap_comp Chapter10/Localization · EpFunctor.orbitMap_id, since naturally equivalent functors have the same orbit map Chapter10/Localization · EpFunctor.NaturallyEquivalent.

`orbitMap_eq`, and likewise $|\Phi'| = |\Phi| \circ |H|$; the factors $|H|$ cancel. Equivalent diagrams have a common refinement, hence the same map `Chapter10/Localization · EPLocalization.Diagram.Equiv.orbitMap_eq`.

Definition 10.3.7 (2017: 10.7) (V10.39) `Chapter10/Localization · EPLocalization.Diagram.orbitMapQ` `Chapter10/Localization · EPLocalization.Diagram.orbitMapQ_mk`. When Φ is an equivalence, $|\Phi| \circ |F|^{-1}$ is a composite of homeomorphisms `Chapter10/Localization · EPLocalization.Diagram.isHomeomorph_orbitMap`.

The composite `Chapter10/Localization · EPLocalization.Diagram.comp` `Chapter10/Localization · EPLocalization.Diagram.id`. For d and $e : Y \xleftarrow{G} B \xrightarrow{\Psi} Z$, the weak fibred product of Φ and G is admissible since G is an equivalence `Chapter10/Localization · EPLocalization.Diagram.admissible`, and π_A is an equivalence (Theorem 10.2.2), so $F \circ \pi_A$ is one. `d.comp e` is the text's $[e] \circ [d]$.

Theorem 10.3.8 (2017: 10.3) (V10.40) `Chapter10/Localization · EPLocalization.Diagram.theorem_10_3_8`, the proof of Appendix §10.6.1. *Step 1, the functor L.* For refinements $H : d' \to d$, $K : e' \to e$ with natural transformations $\tau_{A'} : \Phi' \to \Phi \circ H$ and $\tau_{B'} : G' \to G \circ K$, $L(a', \phi, b') = (H(a'), \tau_{B'}(b') \circ \phi \circ \tau_{A'}(a')^{-1}, K(b'))$ ((10.28), (10.30)) `Chapter10/Localization · EPLocalization.mapMid` `Chapter10/Localization · EPLocalization.mapObj` `Chapter10/Localization · EPLocalization.mapMor` `Chapter10/Localization · EPLocalization.wfpMap` is an sc-smooth functor, entry by entry, with the bookkeeping identity `Chapter10/Localization · GroupoidStr.comp_comp_inv_comp_inv`. In the text's naturality of $\tau_{B'}$ the letter τ_A appears; we read $\tau_{B'}$ (possible misprint). *Step 2, L is an equivalence* `Chapter10/Localization · EPLocalization.isEquivalence_wfpMap`. $\pi_A \circ L = H \circ \pi_{A'}$ holds on the nose `Chapter10/Localization · EPLocalization.projLeft_comp_wfpMap` `Chapter10/Localization · EPLocalization.projRight_comp_wfpMap`; π_A, $\pi_{A'}$ and H are equivalences, and the two-out-of-three rule on the other side from Proposition 10.1.6 `Chapter10/Localization · EpFunctor.IsEquivalence.of_comp_left` applies. The text checks directly that L is full, faithful and a local sc-diffeomorphism. *Step 3, the refinement.* $(F \circ \pi_A) \circ L = F \circ H \circ \pi_{A'} \simeq F' \circ \pi_{A'}$, and $(\Psi \circ \pi_B) \circ L = \Psi \circ K \circ \pi_{B'} \simeq \Psi' \circ \pi_{B'}$ `Chapter10/Localization · EPLocalization.Diagram.IsRefinement.comp`; the text writes the second as "$(\Phi \circ \pi_B) \circ L \simeq \Psi' \circ \pi_{B'}$", read with Ψ (possible misprint). With common refinements on both sides, the class of the composite depends only on the classes `Chapter10/Localization · EPLocalization.Diagram.Equiv.comp`. *Step 4, associativity.* The text identifies $(A \times_Y A') \times_Z A''$ and $A \times_Y (A' \times_Z A'')$; here the reassociation $((a, \phi, a'), \psi, a'') \mapsto (a, \phi, (a', \psi, a''))$ is a functor `Chapter10/Localization · EPLocalization.assocObj` `Chapter10/Localization · EPLocalization.assocMor` `Chapter10/Localization · EPLocalization.assocFunctor`, an equivalence by two out of three `Chapter10/Localization · EPLocalization.projLeft_comp_assocFunctor` `Chapter10/Localization · EPLocalization.isEquivalence_assocFunctor`, and a refinement with identity natural transformations `Chapter10/Localization · EPLocalization.Diagram.isRefinement_assoc` `Chapter10/Localization · EPLocalization.Diagram.equiv_assoc`. *Step 5, units.* $X \xleftarrow{\pi_X} X \times_X A \xrightarrow{\Phi \circ \pi_A} Y$ refines d by π_A, with $F \circ \pi_A \simeq \pi_X$ by $\tau(x, \phi, a) = \phi$ `Chapter10/Localization · EPLocalization.Diagram.isRefinement_id_comp`, and symmetrically on the other side `Chapter10/Localization · EPLocalization.Diagram.isRefinement_comp_id`. The text's proof announces $[1_X] \circ [d] = [d]$ for $d : X \to Y$, which in its order of composition is $[d] \circ [1_X] = [d]$, writes $\tau(a, \phi, a)$ for $\tau(x, \phi, a)$ and "$\psi = \varphi$" for $\psi = \phi$ (possible misprints).

X.18 Definitions 10.3.9 and 10.3.12, Theorem 10.3.10 (2017: Definitions 10.8, 10.9, Theorem 10.4) with Appendix §10.6.2

Definition 10.3.12 (2017: 10.9) (V10.44) `Chapter10/LocalizationCategory · EPLocalization.EPLoc`. The objects are a copy of those of $\mathcal{EP}$ `Chapter10/LocalizationCategory · EPLocalization.EPLoc.toEP_of` `Chapter10/LocalizationCategory · EPLocalization.EPLoc.of_toEP`, the morphisms the quotients of dia-

grams Chapter10/LocalizationCategory · EPLocalization.EPLoc.homMk, with $[d] \gg [e] = [d.\mathrm{comp}\, e]$ Chapter10/LocalizationCategory · EPLocalization.EPLoc.homMk_comp and $\mathrm{id} = [1_X]$ Chapter10/LocalizationCategory · EPLocalization.EPLoc.id_eq; the category laws are Theorem 10.3.8. $[d] = [d']$ iff d and d' are equivalent Chapter10/LocalizationCategory · EPLocalization.EPLoc.homMk_eq_homMk_iff, and every morphism is a $[d]$ Chapter10/LocalizationCategory · EPLocalization.EPLoc.homMk_surjective.

Definition 10.3.9 (2017: 10.8) (V10.41) Chapter10/LocalizationCategory · EPLocalization.EPLoc.IsGeneralizedIso, the isomorphisms of the category Chapter10/LocalizationCategory · EPLocalization.EPLoc.isGeneralizedIso_iff_isIso.

Theorem 10.3.10 (2017: 10.4) (V10.42) Chapter10/LocalizationCategory · EPLocalization.EPLoc.theorem_10_3_10, the proof of Appendix §10.6.2. *Step 1, Φ an equivalence.* The reversed diagram $Y \xleftarrow{\Phi} A \xrightarrow{F} X$ Chapter10/LocalizationCategory · EPLocalization.Diagram.symm. The composite $X \xleftarrow{F\circ\pi_1} A \times_Y A \xrightarrow{F\circ\pi_2} X$ is refined by $X \xleftarrow{F} A \xrightarrow{F} X$ through the diagonal $a \mapsto (a, 1_{\Phi(a)}, a)$ Chapter10/Localization · EPLocalization.diagObj Chapter10/Localization · EPLocalization.diagMor Chapter10/Localization · EPLocalization.diagFunctor, an equivalence since $\pi_1 \circ \Delta = 1_A$ Chapter10/Localization · EPLocalization.isEquivalence_diagFunctor Chapter10/Localization · EPLocalization.Diagram.isRefinement_comp_symm, and that diagram refines 1_X by F Chapter10/Localization · EPLocalization.Diagram.isRefinement_id; so both composites are units Chapter10/LocalizationCategory · EPLocalization.Diagram.equiv_comp_symm Chapter10/LocalizationCategory · EPLocalization.Diagram.equiv_symm_comp. *Step 2, the converse.* Let $[b] = [Y \xleftarrow{G} B \xrightarrow{\Psi} X]$ be an inverse. A diagram $X \leftarrow C \xrightarrow{\Theta} X$ equivalent to 1_X has Θ an equivalence (Propositions 10.1.5 and 10.1.6 applied to a common refinement) Chapter10/LocalizationCategory · EPLocalization.Diagram.isEquivalence_Φ_of_equiv_id; so $\Psi \circ \pi_B$ and $\Phi \circ \pi_{A'}$ are equivalences. *Step 3, (C1).* Φ is an equivalence of categories Chapter10/LocalizationCategory · EPLocalization.isEquivalence_toFunctor_of_comp. Faithfulness is checked on morphisms (h, ϕ, k) with $k = 1_b$; in the text's injectivity argument $A \times_X B$ is read $A \times_Y B$ and $\mathrm{mor}_Y(\Psi(a), \Psi(a'))$ as $\mathrm{mor}_X(\Psi(b), \Psi(b'))$, and in the essential surjectivity "between $\Phi(a)$ and x" as "and y" (possible misprints). *Step 4, (C2).* The text defines $\Gamma(b') = (b', (s|U)^{-1}(b'), \ldots)$, read with $(s|U)^{-1}(\Psi(b'))$ (possible misprint), and then uses that $\Gamma' : U' \to A$ is a local sc-diffeomorphism; Γ' is a composite with Ψ, so as we read it this needs Ψ to be a local sc-diffeomorphism, the other half of (C2), and the step does not hold as we read it. The formal argument: a local inverse κ of the equivalence $\Phi \circ \pi_{A'}$ at (b, ϕ, a) gives the local sc-smooth right inverse $\pi_{A'} \circ \kappa$ of Φ with value a at $\Phi(a)$; Φ is injective near a by a local section $a' \mapsto (a', \phi(a'), b(a'))$ of the local sc-diffeomorphism $\pi_A : A \times_Y B \to A$ and the local injectivity of $\Psi \circ \pi_B$, s and G Chapter10/LocalizationCategory · MPolyfold.IsLocalScDiffeoAt.exists_injOn; an injective map with such a right inverse is a local sc-diffeomorphism Chapter10/LocalizationCategory · MPolyfold.isLocalScDiffeoAt_of_injOn Chapter10/LocalizationCategory · EPLocalization.isLocalScDiffeo_obj_of_comp. *Step 5.* Lemma 10.1.2 Chapter10/LocalizationCategory · EPLocalization.Diagram.isEquivalence_Φ_of_equiv. *(2).* An inverse is unique, so every inverse is the class of the reversed diagram Chapter10/LocalizationCategory · EPLocalization.EPLoc.isIso_homMk_iff Chapter10/LocalizationCategory · EPLocalization.EPLoc.isIso_homMk Chapter10/LocalizationCategory · EPLocalization.EPLoc.inv_homMk.

X.19 Proposition 10.3.11, Theorems 10.3.14 and 10.3.15 (2017: Proposition 10.6, Theorems 10.5, 10.6)

Proposition 10.3.11 (2017: 10.6) (V10.43) Chapter10/LocalizationCategory · EPLocalization.EPLoc.proposition_10_3_11. $||[d]||$ on the quotient Chapter10/LocalizationCategory · EPLocalization.EPLoc.orbitMap Chapter10/

LocalizationCategory · EPLocalization.EPLoc.orbitMap_homMk Chapter10/LocalizationCategory · EPLocalization.EPLoc.continuous_orbitMap Chapter10/LocalizationCategory · EPLocalization.EPLoc.orbitMap_id. The computation before the proposition: an object (a, ϕ, b) of $A \times_Y B$ has $\phi : \Phi(a) \to G(b)$, so $|\Phi(a)| = |G(b)|$, and $|d.\mathrm{comp}\, e| = |e| \circ |d|$ Chapter10/Localization · EPLocalization.Diagram.orbitMap_comp.

Theorem 10.3.14 (2017: 10.5) (V10.45) Chapter10/LocalizationCategory · EPLocalization.EPLoc.theorem_10_3_14. *Step 1.* $d_\Phi = X \xleftarrow{1} X \xrightarrow{\Phi} Y$ Chapter10/LocalizationCategory · EPLocalization.Diagram.ofFunctor and i Chapter10/LocalizationCategory · EPLocalization.EPLoc.localizationFunctor Chapter10/LocalizationCategory · EPLocalization.EPLoc.localizationFunctor_obj Chapter10/LocalizationCategory · EPLocalization.EPLoc.localizationFunctor_map. *Step 2, functoriality.* The composite (10.13) $X \xleftarrow{\pi_X} X \times_Y Y \xrightarrow{\Psi \circ \pi_Y} Z$ refines $d_{\Psi\circ\Phi}$ by π_X, since $\Phi \circ \pi_X \simeq \pi_Y$ (§X.10) Chapter10/LocalizationCategory · EPLocalization.Diagram.isRefinement_ofFunctor_comp. The text states the refinement in the other direction; with Definition 10.3.1 (the refining equivalence goes out of the refinement) it is this one, and the equality of classes is the same. *Step 3, inverses.* For $F \in E$, Theorem 10.3.10 with the legs 1 and F Chapter10/LocalizationCategory · EPLocalization.EPLoc.isInvertedBy_localizationFunctor Chapter10/LocalizationCategory · EPLocalization.EPLoc.inv_localizationFunctor_map, and every generalized map is $i(\Phi) \circ i(F)^{-1}$ Chapter10/LocalizationCategory · EPLocalization.EPLoc.homMk_eq. *Witness.* The pair groupoid of $\mathbb{Z}$ and the point as objects of $\mathcal{EP}$ Chapter10/LocalizationCategory · EPLocalization.Examples.pairEP Chapter10/LocalizationCategory · EPLocalization.Examples.pointEP Chapter10/LocalizationCategory · EPLocalization.Examples.pairToPointEP Chapter10/LocalizationCategory · EPLocalization.Examples.isEquivalence_pairToPointEP: the functor is not an isomorphism of $\mathcal{EP}$ Chapter10/LocalizationCategory · EPLocalization.Examples.not_isIso_pairToPointEP, its image is invertible Chapter10/LocalizationCategory · EPLocalization.Examples.isGeneralizedIso_pairToPoint, with the inverse of Theorem 10.3.14 Chapter10/LocalizationCategory · EPLocalization.Examples.inv_localizationFunctor_map_pairToPoint. *The universal property* mentioned on p. 483 (G.117) is §X.30: i is a localization of $\mathcal{EP}$ at E Chapter10/LocalizationUniversal · EPLocalization.EPLoc.isLocalization.

Theorem 10.3.15 (2017: 10.6) (V10.46) Chapter10/LocalizationCategory · EPLocalization.EPLoc.orbitFunctor Chapter10/LocalizationCategory · EPLocalization.EPLoc.theorem_10_3_15. A functor into Mathlib's `TopCat` by Proposition 10.3.11.

X.20 Propositions 10.3.16, 10.3.17, Remark 10.3.18 (2017: 10.3), Theorem 10.3.19 (2017: 10.7), Definition 10.3.20, Theorem 10.3.21

The reduction Chapter10/LocalizationProperties · EPLocalization.EPLoc.exists_diagram_of_isGeneralizedIso Chapter10/LocalizationProperties · EPLocalization.EPLoc.iff_of_isGeneralizedIso. A generalized isomorphism is some $[d]$, and by Theorem 10.3.10 its Φ is an equivalence; a property invariant under equivalences passes from X to A to Y, as on p. 492.

Proposition 10.3.17 (V10.47) Chapter10/LocalizationProperties · EPLocalization.EPLoc.proposition_10_3_17, by Proposition 10.1.16. **Proposition 10.3.16** (V10.64) Chapter10/LocalizationLR · EPLocalization.EPLoc.proposition_10_3_16, by Proposition 10.1.9. **Theorem 10.3.21** (V10.50) Chapter10/LocalizationProperties · EPLocalization.EPLoc.theorem_10_3_21 Chapter10/LocalizationLR · EPLocalization.EPLoc.theorem_10_3_21_all, by Propositions 10.1.9, 10.1.16, 10.1.19, 10.1.18 and 10.1.17; the text leaves the proof to the reader (G.118, closed).

Theorem 10.3.19 (2017: 10.7) does not hold as we read it (V10.65) Chapter10/LocalizationLRCounterexample · EPLocalization.EPLoc.Theorem_10_3_19 Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexa not_theorem_10_3_19. *The example.* $X = \mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ with the trivial action has (LR): its orbits are points,

so an orbit-preserving β is the identity, the action of 1 Chapter10/LocalizationLRCounterexample · EpGroupoid.Examples.isLR_trivialZ3. $[X \xleftarrow{1} X \xrightarrow{\mathrm{Inv}} X]$ and $[1_X]$ are generalized isomorphisms with the same orbit map that differ Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.theorem_10_3_19_counterexample, the base part of Remark 10.5.5 (§X.23). *The step on p. 494.* The proof arranges $|H| = |H'|$ for equivalences $H, H' : A \to Y$ and uses the families α_a of Proposition 10.1.10 (1) as a natural transformation $H_{\mathcal{U}} \to H'_{\mathcal{U}}$. Here $z \mapsto 1_z : z \to \mathrm{Inv}(z)$ is such a family, but there is no natural transformation $1 \to \mathrm{Inv}$: naturality at the generator g of G_z would give $g = g^{-1}$ Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.not_naturallyEquivalent_id_inv. X is not effective Chapter7/NonVacuity · EpGroupoid.Examples.not_isEffective_trivialZ3. The 2017 Theorem 10.7, without (LR), does not hold as we read it either (G.120, settled).

Theorem 10.3.19 for an effective target (V10.66) Chapter10/LocalizationLRCounterexample · EPLocalization.EPLoc.theorem_10_3_19_of_isEffective, the strongest correct version we prove. *Step 1.* In an effective ep-groupoid a continuous family $v \mapsto k(v) \in G_v$ on an open set is the family of units Chapter10/EquivalenceLREffective · EpGroupoid.eqOn_unit_of_isEffective, so two continuous families $\alpha_z, \alpha'_z : H(z) \to H'(z)$ on an open set agree when H is a local sc-diffeomorphism on objects Chapter10/EquivalenceLREffective · EpFunctor.eqOn_of_isEffective. *Step 2.* The families of Proposition 10.1.10 (1) therefore glue on all of X, and they are natural: at a morphism h, $z \mapsto H'(\sigma(z))^{-1} \circ \alpha(t(\sigma(z))) \circ H(\sigma(z))$, with σ the local inverse of s through h, is another such family Chapter10/EquivalenceLREffective · EpFunctor.naturallyEquivalent_of_isEffective. *Step 3.* For $e = f' \circ f^{-1}$, represented by $Y \xleftarrow{F} A \xrightarrow{\Phi} Y$ with $|\Phi| = |F|$, Step 2 gives $F \simeq \Phi$, so $e = 1_Y$ and $f = f'$, without the weak fibred product and the cover $A_{\mathcal{U}}$ of the text. *Witnesses*, the point Chapter10/LocalizationLRCounterexample · EPLocalization.EPLoc.theorem_10_3_19_of_isEffective_hypotheses Chapter10/EquivalenceLREffective · EquivalenceLREffectiveExamples.naturallyEquivalent_of_isEffective_hypotheses.

Remark 10.3.18 (2017: 10.3) (V10.48) Chapter10/LocalizationProperties · EPLocalization.OrbitChart Chapter10/LocalizationProperties · EPLocalization.OrbitChart.Rel. Reflexive by 1_X Chapter10/LocalizationProperties · EPLocalization.OrbitChart.Rel.refl, symmetric by the inverse Chapter10/LocalizationProperties · EPLocalization.OrbitChart.Rel.symm and transitive by the composite Chapter10/LocalizationProperties · EPLocalization.OrbitChart.Rel.trans, each with Proposition 10.3.11 Chapter10/LocalizationProperties · EPLocalization.OrbitChart.setoid. *Witness* Chapter10/LocalizationProperties · EPLocalization.OrbitChart.rel_pairEP_pointEP. The metrizability of Z is not used. The non-uniqueness of f is shown by the base classes of the example of Remark 10.5.5 (§X.23; G.119, closed).

Definition 10.3.20 (V10.49) Chapter10/LocalizationProperties · EPLocalization.EPreg Chapter10/LocalizationProperties · EPLocalization.EPLocReg, Mathlib full subcategories, with the point as an object of both Chapter10/LocalizationProperties · EPLocalization.Examples.pointReg Chapter10/LocalizationProperties · EPLocalization.Examples.pointLocReg. Remark 10.3.13 has no formal content.

X.21 §10.5: diagrams of strong bundles, $[d]$, $|[D]|$ and γ

Diagrams and refinements (V10.51) Chapter10/StrongBundleLocalization · SBLocalization.SDiagram Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.IsRefinement. A diagram is a middle object of $\mathcal{SEP}$ with a strong bundle equivalence Φ and a morphism Ψ of $\mathcal{SEP}$. A refinement is a strong bundle equivalence H with $\Phi \circ H \simeq \Phi'$ and $\Psi \circ H \simeq \Psi'$, natural equivalence of morphisms of $\mathcal{SEP}$ being Definition 10.4.8 Chapter10/StrongBundleLocalization · SEP.NatEquiv, an equivalence re-

lation compatible with composition on the left Chapter10/StrongBundleLocalization · SEP.NatEquiv.comp_left. The two examples Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.isRefinement_precomp Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.isRefinement_of_natEquiv and the strong bundle Lemma 10.3.2 Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.IsRefinement.trans follow: $H \circ H'$ is a strong bundle equivalence and $\Phi \circ H \circ H' \simeq \Phi' \circ H' \simeq \Phi''$. *The classes.* Having a common refinement Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.Equiv is reflexive and symmetric Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.Equiv.refl Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.Equiv.symm; its transitivity, the strong bundle Lemma 10.3.4, is proved in §X.22 through the weak fibred product of strong bundles. $[D]$ is the class for the generated equivalence relation Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.cls, which is having a common refinement (§X.22); every invariant below is proved invariant under `Equiv`, hence defined on the classes, and a refinement has the class of the refined diagram Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.IsRefinement.equiv Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.cls_eq_cls_of_equiv.

$[d]$ and $|[D]|$ (V10.52) Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.base Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.total Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.base Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.orbitMap. Forgetting the bundles gives the diagram d of the base ep-groupoids, and the total spaces as ep-groupoids $(W, \mathbf{W})$ Chapter10/StrongBundleLocalization · SEP.totalEP give a diagram of total spaces; refinements and equivalences pass to both Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.IsRefinement.base Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.Equiv.base Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.Equiv.total, since a natural equivalence of strong bundle functors covers one of the base functors and is one of the total-space functors. $|[D]|$ is §10.3's orbit map $|\Psi| \circ |\Phi|^{-1}$ of the diagram of total spaces Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.orbitMap, continuous Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.continuous_orbitMap and the same for equivalent diagrams by Lemma 10.3.6 Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.Equiv.orbitMap_eq.

The square $|\mathcal{D}|$ (V10.53) Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.orbitMap_square Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.orbitMap_square. Every orbit of $|W|$ is $|\Phi(w)|$ for some $w \in W''$, $|\Phi|$ being onto; then $|[D]|(|\Phi(w)|) = |\Psi(w)|$ Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.orbitMap_orbitMap_Φ, $|P'(\Psi(w))| = |\psi(P''(w))|$ since Ψ covers ψ, and $|[d]|(|\phi(P''(w))|) = |\psi(P''(w))|$ by Lemma 10.3.6. The printed $|X| \to |X|$ is read with X'.

γ (V10.54) Chapter10/StrongBundleLocalization · EPLocalization.Diagram.exists_isotropyData Chapter10/StrongBundleLocalization · EPLocalization.Diagram.isotropyHom. The data: x'' and a from the essential surjectivity of ϕ, b from $|[d]|(|x|) = |x'|$. γ is the composite of the conjugation by a^{-1}, the inverse of the isomorphism $G_{x''} \to G_{\phi(x'')}$ of the equivalence ϕ (Remark 10.1.12), ψ on isotropy groups and the conjugation by b, with its values Chapter10/StrongBundleLocalization · EPLocalization.Diagram.isotropyHom_spec; for ψ an equivalence each factor is bijective Chapter10/StrongBundleLocalization · EPLocalization.Diagram.bijective_isotropyHom. The germ q and its lift Q of pp. 505–506 are §X.33 (G.124) Chapter10/StrongBundleDiagram · EPLocalization.Diagram.exists_germ_q Chapter10/StrongBundleDiagramLift · SBLocalization.SDiagram.exists_lift_Q.

X.22 Definitions 10.5.1 and 10.5.2 (2017: 10.14 and 10.15), Remark 10.5.3

The weak fibred product of strong bundles: Theorem 10.2.2 for strong bundles (V10.68) `Chapter10/StrongBundleWeakFibredProduct · SBWeakFibredProduct.wfpSEP` `Chapter10/StrongBundleWeakFibredProduct · SBWeakFibredProduct.theorem_10_2_2`. The text introduces refinements and classes "following our earlier construction" (p. 504) and gives no weak fibred product of strong bundles. *The tools.* For a strong bundle W over X and a functor $\pi : A \to X$, the pull-back π^*W over A, with $\mu_\pi(\gamma,(a,w)) = (t(\gamma),\mu(\pi(\gamma),w))$ `Chapter10/StrongBundleWeakFibredProductPullback · EpStrongBundle.pullbackAlong`, whose projection is a strong bundle equivalence when π is an equivalence `Chapter10/StrongBundleWeakFibredProductPullback · EpStrongBundle.isStrongBundleEquivalence_pullbackProjFunctor`; the transport $w \mapsto \mu'(\tau(Pw),\Psi(w))$ of a strong bundle functor along a natural transformation τ `Chapter10/StrongBundleWeakFibredProductPullback · EpStrongBundle.transportFunctor`; and, for a strong bundle equivalence Φ covering ϕ and a strong bundle functor Θ covering $\phi\circ\kappa$, the unique lift Λ covering κ with $\Phi\circ\Lambda = \Theta$, fibrewise $\Lambda(c) = \Phi^{-1}_{\kappa(Pc)}(\Theta(c))$, well defined because Φ is a linear isomorphism on fibres (Proposition 10.4.4) and sc-smooth because it is locally $\Phi^{-1}\circ\Theta$ `Chapter10/StrongBundleWeakFibredProductPullback · EpStrongBundle.invLiftFunctor`. *The construction.* $W\times_{W'}W'' = \pi_Z^*W''$ over $X\times_{X'}X''$; Π_Z is the projection of the pull-back, an equivalence since π_Z is one (Theorem 10.2.2), and Π_X the lift of the transport of $\Psi\circ\Pi_Z$ along the natural transformation $\psi\circ\pi_Z \to \phi\circ\pi_X$ `Chapter10/StrongBundleWeakFibredProduct · SEP.coneHom`, so that $\Phi\circ\Pi_X \simeq \Psi\circ\Pi_Z$ `Chapter10/StrongBundleWeakFibredProduct · SEP.natEquiv_cone`. When Ψ is an equivalence, Π_X is an isomorphism onto π_X^*W followed by its projection, an equivalence `Chapter10/StrongBundleWeakFibredProduct · SBWeakFibredProduct.theorem_10_2_2_right`. *Witness* `Chapter10/StrongBundleWeakFibredProduct · StrongBundleWeakFibredProductExamples.theorem_10_2_2_negSEPHom`: Φ over $-\mathrm{id}$ and $\Psi = 1$, with both projections strong bundle equivalences.

Transitivity: Lemma 10.3.4 for strong bundles (V10.69) `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.lemma_10_3_4` `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.Equiv.trans`. As in §X.16: if w refines D, D' by H, H' and w' refines D', D'' by K, K', the diagram on the weak fibred product of H' and K refines D by $H\circ\Pi_X$ and D'' by $K'\circ\Pi_Z$, both strong bundle equivalences since K is one. Hence $[D] = [D']$ iff D and D' have a common refinement `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.cls_eq_cls_iff`, and the classes of §X.21 are the text's.

The composition: Theorem 10.3.8 for strong bundles (V10.70) `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.comp` `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.Equiv.comp`. For D and $E : W' \xleftarrow{\Phi'} V'' \xrightarrow{\Psi'} W'''$ the middle of the composite is the pull-back of W'' along π_X over the weak fibred product of ψ and ϕ' `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.compMid`, so that its projection $\Pi_{W''}$ is a strong bundle equivalence `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.compLeft`, and $\Pi_{V''}(p,w) = \Phi'^{-1}_z(\mu'(\varphi,\Psi(w)))$ is a lift as above `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.compRight`. If D' refines D by H and E' refines E by K, the lift of $H\circ\Pi_{W''}$ over the functor L of (10.28), (10.30) refines the composite `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.IsRefinement.comp`; associativity is the lift over the reassociation functor of §X.17 `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.isRefinement_assoc` `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.equiv_assoc`, and the units come from sections into the middle `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.unitSection` `Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.equiv_comp_`

id Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.equiv_id_comp. In each proof the square with the projections to the middle of E, or of the last diagram, commutes strictly, because a strong bundle equivalence is injective on fibres. *Witness* Chapter10/StrongBundleLocalizationCategory · StrongBundleLocalizationCategoryExamples.homMk_foldDiagram_comp Chapter10/StrongBundleLocalizationCategory · StrongBundleLocalizationCategoryExamples.nonempty_comp_foldDiagram: for $F = [W' \xleftarrow{P'} (-\mathrm{id})^*W' \xrightarrow{P'} W']$, $F \circ F = 1$, with a nonempty middle.

Definition 10.5.1 (2017: 10.14) (V10.55) Chapter10/StrongBundleLocalization · SBLocalization.SEPLoc Chapter10/StrongBundleLocalization · SBLocalization.SEPLoc.idHom Chapter10/StrongBundleLocalization · SBLocalization.SEPLoc.localizationPrefunctor. The objects are a one-field structure around $\mathcal{SEP}$, the morphisms the classes, the identities $[1_W]$ Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.id; with the composition $[E] \circ [D] = [D \circ E]$ Chapter10/StrongBundleLocalizationCategory · SBLocalization.GenSBMap.comp the laws of the previous paragraph make it a category Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.category (G.123, closed). $\Psi \mapsto [1, \Psi]$ Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.ofHom, first a prefunctor mapping 1_W to $[1_W]$ Chapter10/StrongBundleLocalization · SBLocalization.SEPLoc.localizationPrefunctor_map_id, is a functor by $[1, \Psi'] \circ [1, \Psi] = [1, \Psi' \circ \Psi]$ Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.equiv_ofHom_comp Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.localizationFunctor, and it inverts the strong bundle equivalences Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.isInvertedBy_localizationFunctor.

Definition 10.5.2 (2017: 10.15) (V10.56) Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.IsGeneralizedIso: some representative has Ψ in F (Φ is in F for every diagram). The reversed diagram Chapter10/StrongBundleLocalization · SBLocalization.SDiagram.symm of such a representative, and $[1, \Psi]$ for Ψ in F, give examples Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.isGeneralizedIso_symm Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.isGeneralizedIso_ofHom. *Witness* Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.negDiagram Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.isGeneralizedIso_negDiagram: $[1, P']$ for the projection $P' : (-\mathrm{id})^*W' \to W'$ of §X.11, between two different strong bundles.

Remark 10.5.3 (V10.57) Chapter10/StrongBundleLocalization · SBLocalization.GenSBMap.remark_10_5_3. For a representative with Φ, Ψ in F, ϕ and ψ are equivalences and Φ, Ψ are equivalences of the total spaces (Definition 10.4.1); Theorem 10.3.10 makes $[d]$ and the class of the diagram of total spaces generalized isomorphisms, and Lemma 10.3.6 makes $|[D]|$ a homeomorphism. The strong bundle version of Theorem 10.3.10, which the remark builds into Definition 10.5.2, is read as: the generalized strong bundle isomorphisms are exactly the isomorphisms of $\mathcal{SEP}(F^{-1})$ (next paragraph and §X.34).

Theorem 10.3.10 for strong bundles, the first direction (V10.71; the converse is §X.34) Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.theorem_10_3_10 Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.isIso_of_isGeneralizedIso. If Ψ is a strong bundle equivalence, $D \circ D^{-1}$ and $D^{-1} \circ D$, for the reversed diagram D^{-1}, are refined through sections into their middles Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.equiv_comp_symm Chapter10/StrongBundleLocalizationCategory · SBLocalization.SDiagram.equiv_symm_comp, so $[D]$ is an isomorphism with inverse $[D^{-1}]$ Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.inv_homMk. *Towards the converse.* $[D] \mapsto [d]$ is a functor to $\mathcal{EP}(E^{-1})$ Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.baseFunctor, so an isomorphism $[D]$ gives an isomorphism $[d]$, and Theorem 10.3.10 for the underlying diagram makes ψ an equivalence Chapter10/StrongBundleLocalizationCategory · SBLocalization.SEPLoc.isEquivalence_base_of_isIso. That Ψ itself is a strong bundle equivalence is §X.34 (G.123,

closed for this half too), by a route that replaces the claims (C1), (C2) of Appendix §10.6.2 Chapter10/StrongBundleIsoConverse · SBLocalization.SEPLoc.isIso_iff_isGeneralizedIso. *Witness* Chapter10/StrongBundleLocalizationCategory · StrongBundleLocalizationCategoryExamples.isIso_homMk_negDiagram: the class over $-\mathrm{id}$ of Definition 10.5.2.

X.23 Theorem 10.5.4 (2017: 10.9), Remark 10.5.5, Proposition 10.5.6

The push-forward along a diagram (V10.58) Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.pushforward Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.pullback. For Φ, Ψ in F, $D_*f = \Psi_*\Phi^*f$ with §10.4's pull-back and push-forward, and D^*g is the push-forward along the reversed diagram. That they map section functors to section functors, are mutually inverse and do the same on sc^+-section functors Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.mapsTo_pushforward Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.invOn_pullback_pushforward Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.bijOn_pushforward Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.bijOn_pushforward_plus comes from Theorem 10.4.5. *The text's step* Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.pushforward_eq_of_isRefinement: for a refinement by H, $\Psi_*\Phi^*f = \Psi_*H_*H^*\Phi^*f = (\Psi\circ H)_*(\Phi\circ H)^*f = \Psi'_*\Phi'^*f$, by Theorem 10.4.5 for H, Proposition 10.4.4, and Propositions 10.4.2, 10.4.3 for the naturally equivalent pairs, which have the same orbit maps. *Through the orbit spaces.* Step 1: $|\mu(\sigma,w)| = |w|$ Chapter10/StrongBundleLocalizationSections · EpStrongBundle.π_μ, so a section functor takes isomorphic objects to one orbit Chapter10/StrongBundleLocalizationSections · EpStrongBundle.π_eq_π_of_isFunctorialSection, and two section functors with $|f(x)| = |g(x)|$ for all x agree: a morphism $(\sigma, f(x)) : f(x) \to g(x)$ has $\sigma \in G_x$, and $f(x) = \mu(\sigma, f(x))$ since f is functorial Chapter10/StrongBundleLocalizationSections · EpStrongBundle.eq_of_forall_π_eq. Step 2: $|(D_*f)(x')| = |[D]|(|f(x)|)$ whenever $|[d]|(|x|) = |x'|$ Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.π_pushforward. Step 3: $|[d]|$ is determined by $|[D]|$ through the square, $|P|$ being onto Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.base_orbitMap_eq_of_orbitMap_eq. Hence diagrams with the same $|D|$ have the same push-forward Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.pushforward_eq_of_orbitMap_eq and, reversed, the same pull-back Chapter10/StrongBundleLocalizationSections · SBLocalization.SDiagram.pullback_eq_of_orbitMap_eq.

Theorem 10.5.4 (2017: 10.9) (V10.59) Chapter10/StrongBundleLocalizationSections · SBLocalization.GenSBMap.theorem_10_5_4. $[D]_*$ and $[D]^*$ use a representative with Ψ in F chosen once Chapter10/StrongBundleLocalizationSections · SBLocalization.GenSBMap.rep Chapter10/StrongBundleLocalizationSections · SBLocalization.GenSBMap.pushforward Chapter10/StrongBundleLocalizationSections · SBLocalization.GenSBMap.pullback; every other such representative has the same $|D|$, an invariant of the class, hence the same push-forward and pull-back Chapter10/StrongBundleLocalizationSections · SBLocalization.GenSBMap.pushforward_eq Chapter10/StrongBundleLocalizationSections · SBLocalization.GenSBMap.pullback_eq. The rest is the previous paragraph for the chosen representative, the last assertion with Step 3. The Fred part (G.125) Chapter10/FredholmEquivalence · SBLocalization.GenSBMap.theorem_10_5_4_fred and "isomorphism" as a linear isomorphism Chapter10/SectionFunctorLinear2021 · SBLocalization.GenSBMap.pushforwardEquiv are §X.31. *Witnesses* Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.bijOn_pushforward_negDiagram Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.pushforward_foldDiagram: $W' \xleftarrow{P'} (-\mathrm{id})^*W' \xrightarrow{P'} W'$ refines $1_{W'}$ Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.isRefinement_foldDiagram Chapter10/

StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.cls_foldDiagram, so its push-forward is that of $[1_{W'}]$, the identity Chapter10/StrongBundleLocalizationExamples · SBLocalization.SDiagram.pushforward_id.

Remark 10.5.5 (V10.60) Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.remark_10_5_5. The positive half is the last assertion of Theorem 10.5.4 Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.pushforward_inv_eq_pushforward_id; for the negative half the text gives no example. *The invariant* Chapter10/StrongBundleLocalizationExamples · EPLocalization.Diagram.IsotropyRel: $g \in G_x$ and $g' \in G_{x'}$ are related by d if $g = a \circ \phi(k) \circ a^{-1}$ and $g' = b \circ \psi(k) \circ b^{-1}$ for some z, $k \in G_z$, a, b; the relation contains the graph of every γ Chapter10/StrongBundleLocalizationExamples · EPLocalization.Diagram.isotropyRel_isotropyHom, and it does not change under refinement, through the conjugations by the natural transformations Chapter10/StrongBundleLocalizationExamples · EpNatTrans.isotropyHom_eq Chapter10/StrongBundleLocalizationExamples · EPLocalization.Diagram.IsRefinement.isotropyRel_iff, nor under equivalence Chapter10/StrongBundleLocalizationExamples · EPLocalization.Diagram.Equiv.isotropyRel_iff. *The example.* $W = \mathbb{R} \times \mathbb{R}^k \to \mathbb{R}$ over $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ with $\mu((g,x),w) = w$ Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.z3EpBundle, and Inv over $(g,x) \mapsto (g^{-1},x)$, a functor since $\mathbb{Z}/3$ is abelian and a strong bundle equivalence as its own inverse Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.z3InvHom Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.z3InvHom_mem_equivalences. Inv is the identity on objects, so $|[\mathrm{Inv}]| = |[1_W]|$ Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.orbitMap_ofHom_z3InvHom and the base orbit maps agree Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.base_orbitMap_ofHom_z3InvHom. For $[1_W]$ the generator of $G_0 = \mathbb{Z}/3$ is related to itself Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.isotropyRel_id; for $[\mathrm{Inv}]$ a related pair is (k,k^{-1}) up to conjugation, which is trivial in $\mathbb{Z}/3$, and the generator is not its own inverse Chapter10/StrongBundleLocalizationExamples · StrongBundleLocalizationExamples.not_isotropyRel_inv. So the base classes differ, and with them the classes. By Remark 10.5.3 the base classes are two distinct generalized isomorphisms with the same orbit map: the non-uniqueness claimed in Remark 10.3.18 (G.119, closed).

Proposition 10.5.6 (V10.61) Chapter10/StrongBundleLocalizationSections · SBLocalization.GenSBMap.iff_of_isGeneralizedIso. A representative with Φ, Ψ in F carries a property invariant under strong bundle equivalences from W to W'' to W'. For the local regularity property this is Proposition 10.4.6 Chapter10/StrongBundleLocalRegularity · EpStrongBundle.proposition_10_4_6, with Definition 8.4.2 read as `IsLRLocal`, and Proposition 10.5.6 follows Chapter10/StrongBundleLocalRegularity · SBLocalization.proposition_10_5_6 (G.122, G.126, closed); the text's "see Proposition 10.4.7" is read as Proposition 10.4.6.

Theorem 10.5.7 (2017: 10.10) does not hold as we read it (V10.67) Chapter10/LocalizationLRCounterexample · SBLocalization.Theorem_10_5_7 Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.not_theorem_10_5_7. The strong bundle of Remark 10.5.5 has the local regularity property of Definition 8.4.2, its orbits being points Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.isLR_z3EpBundle, and $[\mathrm{Inv}] \neq [1_W]$ with the same orbit map. The text's proof, "immediately from Proposition 10.4.7", meets the step of Theorem 10.3.19 (§X.20); the 2017 Theorem 10.10, without local regularity, does not hold as we read it either (G.127, settled).

Theorem 10.5.7 over an effective base of the target (V10.67) Chapter10/LocalizationLREffectiveBundle · SBLocalization.theorem_10_5_7_of_isEffective Chapter10/LocalizationLRBundleBase · SBLocalization.theorem_10_5_7_of_isEffective_of_isLRLocal, the strong bundle analogue of the effective Theorem 10.3.19. *Step 1, the bases.* $|\Phi| = |\Psi|$ on total spaces gives $|\phi| = |\psi|$ on the bases Chapter10/LocalizationLREffectiveBundle · SEP.orbitMap_

base_eq, since the projection of a strong bundle is open Chapter10/LocalizationLREffectiveBundle · StrongBundle.isOpenMap_proj. *Step 2, the natural equivalence.* For strong bundle equivalences $F, G : W'' \to W'$ with $|F| = |G|$ and an effective base of W', the base transformation $\tau : \phi_F \to \phi_G$ is that of §X.20, Step 2; then $G(w) = \mu'(\tau(P(w)), F(w))$: both sides are continuous in w and agree over the regular points, where only one morphism $\phi_F(P(w)) \to \phi_G(P(w))$ exists, and these are dense Chapter10/LocalizationLREffectiveBundle · SEP.natEquiv_of_isEffective. The families of Step 2 come from (LR) of a base (Proposition 10.1.10) in the first form, and in the second from Definition 8.4.2 read for strong bundle isomorphisms of $W|U(x)$ Chapter10/LocalizationLRBundleBase · EpStrongBundle.IsLRLocal through Proposition 10.4.7 on the bases Chapter10/LocalizationLRBundleBase · SEP.exists_family_of_isLRLocal (§X.32). *Step 3.* For D, D' with $|[D]| = |[D']|$, the weak fibred product of Φ and Φ' refines both: $\Phi \circ \Pi_X \simeq \Phi' \circ \Pi_Z$ by the strong bundle Theorem 10.2.2 and $\Psi \circ \Pi_X \simeq \Psi' \circ \Pi_Z$ by Step 2. *Hypotheses.* The effectiveness of the base of the target is added in both forms and is not derived from the text; (LR) of a base is added in the first form and is not derived from the text either. The second form needs only the local regularity property of the target bundle, and it implies the formal (LR) of strong bundles Chapter10/LocalizationLRBundleBase · EpStrongBundle.IsLRLocal.isLR. Effectiveness cannot be dropped under this reading: the bundle over $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ has the property Chapter10/LocalizationLRBundleBase · LocalizationLRBundleBaseExamples.isLRLocal_z3EpBundle, and the conclusion fails there Chapter10/LocalizationLRBundleBase · LocalizationLRBundleBaseExamples.not_theorem_10_5_7_of_isLRLocal. *Witnesses,* $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ with $[1_W]$ Chapter10/LocalizationLREffectiveBundle · LocalizationLREffectiveBundleExamples.theorem_10_5_7_of_isEffective_hypotheses Chapter10/LocalizationLRBundleBase · LocalizationLRBundleBaseExamples.theorem_10_5_7_of_isEffective_of_isLRLocal_hypotheses, and the local regularity property of a trivial bundle Chapter10/LocalizationLRBundleBase · EpStrongBundle.isLRLocal_trivial.

X.24 Witnesses and the hypotheses

Hypotheses taken, with their witnesses. The nonempty object set in Proposition 10.1.3: the covering of $\mathbb{Z}/2 \ltimes \mathbb{R}$ (§X.2). `Admissible`: every equivalence (§X.9), and the pair groupoid of $\mathbb{Z}$ over the point, and $\pm$id on $\mathbb{Z}/2 \ltimes \mathbb{R}^2$ (§X.10). Proposition 10.1.9 for the lifts, once a hypothesis of Proposition 10.1.19, is proved (§X.5). The two Hausdorff hypotheses of Proposition 10.1.14 are the text's. The effectiveness of the target in Theorem 10.3.19: the point (§X.20). The effectiveness of the base of the target in Theorem 10.5.7, with (LR) of a base or the local regularity property of the target bundle: $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ (§X.23). Definition 8.4.2 read for strong bundle isomorphisms of $W|U(x)$ is a reading, not an added hypothesis; it holds for trivial bundles (§§X.23, X.32). Otherwise §§10.3–10.5 and the new work of §§X.27–X.34 take no hypothesis.

Every definition has a non-identity witness. Equivalences: $\mathbb{Z} \to$ pt, the refinement of $\mathbb{Z}/2 \ltimes \mathbb{R}$, $-$id of $\mathbb{Z}/2 \ltimes \mathbb{R}^2$; the weak fibred product: §X.10; strong bundle equivalences, push-forwards, natural equivalences of strong bundle functors, morphisms of $\mathcal{SEP}$: the bundle over $-$id (§§X.11–X.15); equivalent diagrams, generalized isomorphisms that do not come from isomorphisms, equivalent pairs (X, β) and objects of $\mathcal{EP}_{reg}$: the pair groupoid of $\mathbb{Z}$ and the point (§§X.16–X.20); refinements of diagrams of strong bundles, weak fibred products of strong bundles, composites in $\mathcal{SEP}(F^{-1})$, generalized strong bundle isomorphisms with their inverses and push-forwards: the bundle over $-$id, and distinct classes with the same orbit map: the bundle over $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ (§§X.22, X.23). The subcategory $\mathcal{EP}_{lreg}$: the point (§X.27); an orbit-preserving sc-diffeomorphism that is no $\hat{g}$, and an ep-groupoid without (LR): η on $\mathbb{Z}/2 \ltimes Y$ of Appendix §10.6.3 (§X.28); the hypotheses of Proposition 10.4.7: $\Phi = \Psi = 1$ on $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ (§X.32). The other results of §§X.29–X.34 add no hypothesis. The hypotheses of Proposition 10.1.10 and of the

effective version of Theorem 10.3.19 are witnessed on the point (§§X.5, X.20).

X.25 What is not formalized

Nothing. Every gap of Chapter 10 is closed: no item is open, none is formalized only in part, and none is set aside as having nothing to formalize. The list below says where each former gap is now proved. The only narrower row is V10.66, Theorem 10.3.19 for an effective target (§X.20).

- §10.1: $\mathcal{EP}_{lreg}$ (G.111, §X.27) `Chapter10/LocalRegularitySubcategory · EP.lreg` `Chapter10/LocalRegularitySubcategory · EP.lreg_iff_of_isEquivalence`; Remark 10.1.8 and Appendix §10.6.3 with the appendix's own projections (G.112, §X.28) `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.remark_10_1_8`. Propositions 10.1.9, 10.1.10 and 10.1.19 (G.113–G.115) are closed by §§X.5, X.7.
- §10.2: the structures induced from the triple products (G.116, §X.29) `Chapter10/WeakFibredProductTriple · WeakFibredProduct.theorem_10_2_2_triple`.
- §10.3: the universal property of the localization (G.117, §X.30) `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.lift` `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.liftMap_comp`. Proposition 10.3.16 and Theorem 10.3.21 (G.118) are closed by §X.20, and the non-uniqueness in Remark 10.3.18 (G.119) by §X.23. Theorem 10.3.19 (G.120) is settled by §X.20: it does not hold as we read it, and holds for an effective target. Remark 10.3.13 has no formal content.
- §10.4: the Fred part of Theorem 10.4.5 (G.121, §X.31) `Chapter10/FredholmEquivalence · EpStrongBundle.theorem_10_4_5_fred`; Propositions 10.4.6 and 10.4.7 (G.122, §X.32), with Definition 8.4.2 read as `IsLRLocal` `Chapter10/StrongBundleLocalRegularity · EpStrongBundle.proposition_10_4_6` `Chapter10/StrongBundleLocalFamilies · EpStrongBundle.proposition_10_4_7`.
- §10.5: the converse half of the strong bundle Theorem 10.3.10 (G.123, §X.34; the other parts are closed by §X.22) `Chapter10/StrongBundleIsoConverse · SBLocalization.SEPLoc.isIso_iff_isGeneralizedIso`; (10.24) with generalized vertical maps, and the local expressions q, Q (G.124, §X.33) `Chapter10/StrongBundleDiagram · SBLocalization.GenSBMap.square_10_24` `Chapter10/StrongBundleDiagram · EPLocalization.Diagram.exists_germ_q` `Chapter10/StrongBundleDiagramLift · SBLocalization.SDiagram.exists_lift_Q`; the Fred part of Theorem 10.5.4 (G.125, §X.31) `Chapter10/FredholmEquivalence · SBLocalization.GenSBMap.theorem_10_5_4_fred`; Proposition 10.5.6 (G.126, §X.32) `Chapter10/StrongBundleLocalRegularity · SBLocalization.proposition_10_5_6`. Theorem 10.5.7 (G.127) is settled by §X.23: it does not hold as we read it, and holds over an effective base of the target.

X.26 What the formalization taught us

The equivalences of §10.1 are the sc-smooth versions of equivalences of categories, and most proofs of the section are categorical arguments plus one local fact: a functor which is a local sc-diffeomorphism on objects at $s(\varphi)$ is one at $t(\varphi)$. The text uses this fact silently in Proposition 10.1.6, where the argument covers only the image of F; with it the proof is two lines. Proposition 10.1.5, quoted without proof, and the fullness and faithfulness of TF, left to the reader, are short once tangent morphisms are known to be determined by their base and source vector. The invariance results new in 2021 split into two kinds: those about $\mathbf{X}^T$ ((LUC), the reduced groupoids, (SLUC)) go through Theorem 7.2.22 and one closure argument; those about natural representations ((LR), (SLR), Proposition 10.1.10) need natural representations carried along $Q = \hat{\psi} \circ F$, which is done by restricting a natural representation at the

target rather than by transporting Γ. The local families of Proposition 10.1.10 are not natural in general, and that is where Theorem 10.3.19 does not hold as we read it: on $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ with the trivial action, which has (LR) because its orbits are points, the identity and the inversion have the same orbit map and are not naturally equivalent; over an effective target the families are unique and glue, and the theorem holds without the weak fibred product of its proof. In §10.2 the weak fibred product needs much less than an equivalence: one local sc-diffeomorphism on objects for the structure, nothing for properness. In §10.3 the two places where the text argues with spaces, "the same space" for the associativity and the direct check that L is an equivalence, become functors and two-out-of-three arguments, and the local half of the hard direction of Theorem 10.3.10 needs a different route, through a local right inverse and local injectivity. In §10.4 the push-forward is well defined on section functors because of fullness (10.22), and once (10.22) is in hand its sc-smoothness is a local formula with two local inverses; Propositions 10.4.2–10.4.4 do not need sc-smoothness at all. In §10.5 the push-forward along a generalized strong bundle isomorphism is best seen through the orbit spaces: a section functor is determined by the orbits of its values, so the push-forward depends only on $|[D]|$, which gives the independence of the representative and the last assertion of Theorem 10.5.4 at once; and the example the text does not give for Remark 10.5.5 needs an invariant finer than the orbit maps, the relation of the isotropy homomorphisms γ, which also settles the non-uniqueness left informal in Remark 10.3.18. The weak fibred product of strong bundles, which the text leaves to the reader, is best taken as a pull-back: one projection is then a strong bundle equivalence by construction, and since strong bundle equivalences are injective on fibres, the squares in the proofs of transitivity, composition and associativity commute strictly, so that the proofs of §10.3 carry over.

What the closing of the gaps shows. First, the example of Appendix §10.6.3 needs no more than the scale and the loss families of Chapter 1: $\pi_{|s|}$ and the map η are differences and sums of loss families, and the failure of (LR) comes down to the observation that in a natural representation of a translation groupoid each $\Phi(g)$ is the action of g itself, by connectedness. Second, the universal property of the localization reduces to one fact: every functor that inverts the equivalences identifies naturally equivalent functors, through the cylinder $X \times_Y Y$, whose projection to X is an equivalence with sections s_τ. Third, Definition 8.4.2 must be read for strong bundle isomorphisms of $W|U(x)$ alone. Asked only of maps defined on all of W, it cannot be applied to the conjugates $H^{-1} \circ B \circ H$ of the proof of Proposition 10.4.6, which live over $U(x)$; read locally, Propositions 10.4.6, 10.4.7 and 10.5.6 follow the proofs of Propositions 10.1.9 and 10.1.10 with transports along families of morphisms in place of $\hat{\psi}$. Fourth, the converse half of the strong bundle Theorem 10.3.10 does not need strong bundle versions of the claims (C1), (C2) of the appendix: the two composites with the inverse class give fibrewise injectivity and local right inverses separately. The Fred parts of Theorems 10.4.5 and 10.5.4, called clear in the text, are the one place where a strong bundle equivalence is not a pull-back along a global isomorphism; the push-forward is handled with the action of the morphisms $\sigma : \phi(y) \to x'$, which is itself a local strong bundle isomorphism.

X.27 The subcategory $\mathcal{EP}_{lreg}$ (2021 p. 461)

The subcategory (V10.74) `Chapter10/LocalRegularitySubcategory · EP.lreg` `Chapter10/LocalRegularitySubcategory · EP.Lreg`. The text introduces, new in 2021, the full subcategory of $\mathcal{EP}$ generated by the ep-groupoids with the local regularity property (Definition 7.4.19). It is an object property of $\mathcal{EP}$ with Mathlib's full subcategory, whose inclusion is fully faithful `Chapter10/LocalRegularitySubcategory · EP.fullyFaithful_ι_lreg`. *Step 1, along equivalences.* For an equivalence $F : X \to Y$, $X \in \mathcal{EP}_{lreg}$ iff $Y \in \mathcal{EP}_{lreg}$, by Proposition 10.1.9 (§X.5) `Chapter10/LocalRegularitySubcategory · EP.lreg_iff_of_isEquivalence`;

this is the closing sentence of the proof of Proposition 10.1.9 on p. 469. *Step 2, isomorphisms of $\mathcal{EP}$.* An isomorphism of $\mathcal{EP}$ is an equivalence by (E1), so the property is closed under isomorphisms `Chapter10/LocalRegularitySubcategory · EP.isClosedUnderIsomorphisms_lreg`. *Step 3, in $\mathcal{EP}(E^{-1})$.* The same object property on the localization `Chapter10/LocalRegularitySubcategory · EPLocalization.EPLoc.lreg` is closed under the isomorphisms there, since an isomorphism is $[X \xleftarrow{F} A \xrightarrow{\Phi} Y]$ with F, Φ equivalences (Theorem 10.3.10) and Step 1 applies twice `Chapter10/LocalRegularitySubcategory · EPLocalization.EPLoc.isClosedUnderIsomorphisms_lreg`; the middle of a diagram out of an object of $\mathcal{EP}_{lreg}$ is in $\mathcal{EP}_{lreg}$ `Chapter10/LocalRegularitySubcategory · EPLocalization.EPLoc.lreg_A_of_lreg`. *Witness*, the point `Chapter10/LocalRegularitySubcategory · EP.lreg_pointEP Chapter10/LocalRegularitySubcategory · EP.Lreg.point`.

X.28 Remark 10.1.8 and Appendix §10.6.3 (2021 pp. 467, 519)

The example as printed (V10.75) `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.remark_10_1_8`. Remark 10.1.8, new in 2021, says that an sc-diffeomorphism β of $U(x)$ with $|\beta(y)| = |y|$ need not be of the form $y \mapsto g * y$, and Appendix §10.6.3 gives the example. *Step 1, the scale and the retraction.* $F = \mathbb{R} \oplus L^2(\mathbb{R})$ with $F_m = \mathbb{R} \oplus H^{m,\delta_m}(\mathbb{R})$ `Chapter7/LineSobolevScale · ZhouLine.lineSc`, and the family π_t of Subsection 1.4.4 `Chapter7/ZhouRetraction · ZhouLine.zhouFam Chapter7/ZhouRetraction · ZhouLine.isLossFamily_zhouFam`. $\pi_{|s|} = \pi_s + \pi_{-s}$ is a loss family `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.isLossFamily_piAbs`, by sums and reflections of loss families `Chapter10/ZhouExample · IsLossFamily.add Chapter10/ZhouExample · IsLossFamily.comp_neg`, so $r(s,f) = (s, \pi_{|s|}f)$ is an sc-smooth retraction `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.Rt₂` with image Y `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.O₂`; $\mathbb{Z}/2$ acts by $(-1) * (s,f) = (s,-f)$, sc-smoothly `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.isScSmoothMap_smul₂`, and $X = \mathbb{Z}/2 \ltimes Y$ `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.X₂`. *Step 2, η.* $\eta(s,f) = (s,f)$ for $s \le 0$ and $(s,-f)$ for $s > 0$ `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.η0_of_nonpos Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.η0_of_pos` is, on Y, the map $(s,f) \mapsto (s, (\pi_{-s} - \pi_s)f)$, with $\pi_{-s} - \pi_s$ a loss family `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.isLossFamily_famη Chapter10/ZhouExample · IsLossFamily.sub`; it is its own inverse `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.η0_η0`, hence an sc-diffeomorphism `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.isScDiffeoOn_η0` fixing 0 `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.η0_o₂`, and $\eta(y)$ is y or $(-1) * y$, so $|\eta(y)| = |y|$ `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.π_η0`. *Step 3, no g.* The points $(\pm\frac{1}{n+1}, \frac{1}{n+1}\beta(\cdot + e^{n+1}))$ lie in Y and tend to 0 `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.ptσ Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.tendsto_ptσ`; on those with $s > 0$, $\eta(y) = -y \ne y$, and on those with $s < 0$, $\eta(y) = y \ne -y$, so on no neighbourhood of 0 is η the action of one g `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.exists_η0_ne_smul`. *Step 4, (LR) fails.* In a natural representation at 0, $\Gamma(g,\cdot)$ has a constant group component on the connected U, so $\Phi(g)$ is $y \mapsto g * y$ there `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.naturalRep_Φ_eq`. η maps U into itself, being the identity or the action of -1 pointwise, so it is an orbit-preserving sc-diffeomorphism of U; (LR) would make it $\Phi(g)$ on U, against Step 3 `Chapter10/ZhouExampleRealScale · EpGroupoid.Examples.ZhouTenSix.not_isLR`. *The variant* with the moving projections of Remark 4.1.3 and η of the opposite sign convention `Chapter10/ZhouExample · ZhouSigma.remark_10_1_8 Chapter10/ZhouExample · ZhouSigma.not_isLR` is kept.

X.29 Theorem 10.2.2 (2017: 10.2): the structures induced from the triple products

The last sentence of the statement `Chapter10/WeakFibredProductTriple · WeakFibredProduct.theorem_10_2_2_triple`. The text says that the object set $L \subseteq X \times \mathbf{Y} \times Z$ and the morphism set $\mathbf{L} \subseteq \mathbf{X} \times \mathbf{Y} \times \mathbf{Z}$ are sub-M-polyfolds and carry the induced structures; §X.9 builds the structures iteratively, $L = X \,{}_F\!\times_s (\mathbf{Y}\,{}_t\!\times_G Z)$ inside $X \times (\mathbf{Y}\,{}_t\!\times_G Z)$. *Step 1, products with a sub-M-polyfold.* For a sub-M-polyfold $A \subseteq N$, $X \times A$ is a sub-M-polyfold of $X \times N$ `Chapter10/WeakFibredProductTriple · MPolyfold.isSubMPolyfold_univ_prod`, and the subtype $X \times A$ with the induced structure is sc-diffeomorphic to $X \times A$ with the product of the structure of A `Chapter10/WeakFibredProductTriple · MPolyfold.prodSubtypeMk` `Chapter10/WeakFibredProductTriple · MPolyfold.isScDiffeoOn_prodSubtype`. *Step 2, transitivity.* A sub-M-polyfold of an M-polyfold sc-diffeomorphic to a sub-M-polyfold $S \subseteq M$ is a sub-M-polyfold of M `Chapter10/WeakFibredProductTriple · MPolyfold.isSubMPolyfold_image_of_isScDiffeoOn`. *Step 3, the triple sets.* The triple-product sets `Chapter10/WeakFibredProductTriple · WeakFibredProduct.objSetTriple` `Chapter10/WeakFibredProductTriple · WeakFibredProduct.morSetTriple` are the images of the iterated ones under the reassociation $(x,(\phi,z)) \mapsto (x,\phi,z)$ `Chapter10/WeakFibredProductTriple · WeakFibredProduct.Obj.toTriple` `Chapter10/WeakFibredProductTriple · WeakFibredProduct.objSetTriple_eq`, hence sub-M-polyfolds by Steps 1, 2 `Chapter10/WeakFibredProductTriple · WeakFibredProduct.isSubMPolyfold_objSetTriple` `Chapter10/WeakFibredProductTriple · WeakFibredProduct.isSubMPolyfold_morSetTriple`. *Step 4.* The reassociations are sc-diffeomorphisms of the iterated structures onto the induced ones, so the two structures agree. Only the admissibility of §X.9 is used (G.116).

X.30 The universal property of the localization (2021 p. 483 and Theorem 10.3.14)

$i : \mathcal{EP} \to \mathcal{EP}(E^{-1})$ is a localization `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.isLocalization` `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.universal_property`. The text introduces $\mathcal{EP}(E^{-1})$ as the category in which the equivalences become invertible universally. *Step 1, the cylinder.* For a natural transformation $\tau : F \to F'$ of functors $X \to Y$, the weak fibred product $X \times_Y Y$ of F and 1_Y receives the sc-smooth section $s_\tau(x) = (x, \tau(x), F'(x))$ `Chapter10/LocalizationUniversal · EPLocalization.secObj` `Chapter10/LocalizationUniversal · EPLocalization.secFunctor`, with $\pi_X \circ s_\tau = 1_X$ and $\pi_Y \circ s_\tau = F'$ `Chapter10/LocalizationUniversal · EPLocalization.secHom_cylLeft` `Chapter10/LocalizationUniversal · EPLocalization.secHom_cylRight`. *Step 2, natural equivalence is inverted.* π_X is an equivalence (Theorem 10.2.2), so for every functor L inverting E, $L(s_\sigma) = L(\pi_X)^{-1}$ for every σ, and $L(F') = L(s_\tau) \circ L(\pi_Y) = L(s_{1_F}) \circ L(\pi_Y) = L(F)$ `Chapter10/LocalizationUniversal · EPLocalization.map_eq_of_naturallyEquivalent`. *Step 3, the lift.* $L'[X \xleftarrow{F} A \xrightarrow{\Phi} Y] = L(F)^{-1} \circ L(\Phi)$ `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.liftMap`. For a refinement by H, $L(F') = L(H) \circ L(F)$ and $L(\Phi') = L(H) \circ L(\Phi)$ by Step 2, and the factors $L(H)$ cancel `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.liftMap_eq_of_isRefinement` `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.liftMap_eq_of_equiv`. *Step 4, functoriality.* The identity `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.liftMap_id`, and composites through the square $L(\pi_A) \circ L(\Phi) = L(\pi_B) \circ L(G)$, which is Step 2 for the natural equivalence of the weak fibred product (§X.10) `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.liftMap_comp` `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.lift`. *Step 5, factorization and uniqueness.* $i \circ L' = L$ `Chapter10/LocalizationUniversal · EPLocalization.EPLoc.fac`, and L' is unique because every generalized map is $i(\Phi) \circ i(F)^{-1}$ (Theorem 10.3.14) `Chapter10/`

LocalizationUniversal · EPLocalization.EPLoc.uniq; this is Mathlib's strict universal property for every target category Chapter10/LocalizationUniversal · EPLocalization.EPLoc.strictUniversalPropertyFixedTarget (G.117).

X.31 Theorems 10.4.5 and 10.5.4 (2017: 10.8 and 10.9): the Fred parts, and linearity

Part I's half. An sc-Fredholm germ stays one along a local strong bundle isomorphism: such an isomorphism Chapter3/FredholmPullbackIso · StrongBundle.LocalIso transports charts Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.transportChart Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.isChart_transportChart and germs Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.isScFredholmGerm, and the sc-Fredholm property of a section is local Chapter3/FredholmPullbackIso · StrongBundle.isScFredholmSection_of_forall.

Theorem 10.4.5, the Fred part (V10.27) Chapter10/FredholmEquivalence · EpStrongBundle.theorem_10_4_5_fred. The text calls it clear. *Step 1.* A local strong bundle isomorphism of Definition 10.4.1 (2) is one of Part I Chapter10/FredholmEquivalence · StrongBundle.IsStrongBundleIsoOn.toLocalIso. *Step 2, Φ^*.* Near x_0, $\Phi^* f'$ is the pull-back of f' along that isomorphism (§X.14, Step 1) Chapter10/FredholmEquivalence · EpStrongBundle.IsStrongBundleEquivalence.exists_localIso_pullback, so it is sc-Fredholm when f' is, in the germ reading of Definition 3.1.18 and with tame germ data Chapter10/FredholmEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScFredholmSection_pullback Chapter10/FredholmEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScFredholmSectionTame_pullback. *Step 3, the action of a morphism.* For a local section α of s, $w \mapsto \mu(\alpha(P(w)), w)$ Chapter10/FredholmEquivalence · EpStrongBundle.sectionAct is a local strong bundle isomorphism $W|t(T) \to W|s(T)$ along which every section functor is its own pull-back, by functoriality (10.16) Chapter10/FredholmEquivalence · EpStrongBundle.exists_localIso_mor. *Step 4, Φ_*.* The push-forward is not a pull-back along a global isomorphism, ϕ being only essentially surjective. Near x' with $\sigma : \phi(y) \to x'$, $\Phi_* f$ is $\Phi \circ f \circ \phi^{-1}$ near $\phi(y)$, sc-Fredholm by Step 2 for the inverse isomorphism, and near x' it is its own pull-back along the action of σ (Step 3) Chapter10/FredholmEquivalence · EpStrongBundle.IsStrongBundleEquivalence.exists_localIso_pushforward Chapter10/FredholmEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScFredholmSection_pushforward Chapter10/FredholmEquivalence · EpStrongBundle.IsStrongBundleEquivalence.isScFredholmSectionTame_pushforward. *Step 5.* With §X.12, Φ_* and Φ^* restrict to inverse bijections of the sets of sc-Fredholm section functors (G.121).

Theorem 10.5.4, the Fred part (V10.59) Chapter10/FredholmEquivalence · SBLocalization.GenSBMap.theorem_10_5_4_fred. $D_* = \Psi_* \Phi^*$ preserves the sc-Fredholm property by the above Chapter10/FredholmEquivalence · SBLocalization.SDiagram.mapsTo_pushforward_fred, and so does D^* Chapter10/FredholmEquivalence · SBLocalization.SDiagram.mapsTo_pullback_fred; with §X.23 they are inverse bijections Chapter10/FredholmEquivalence · SBLocalization.SDiagram.bijOn_pushforward_fred, on the chosen representative of the class (G.125).

"Isomorphism" as a linear isomorphism Chapter10/SectionFunctorLinear2021 · SBLocalization.GenSBMap.pushforwardEquiv Chapter10/SectionFunctorLinear2021 · SBLocalization.GenSBMap.plusPushforwardEquiv. *Step 1.* $\Gamma(P, \mu)$ and $\Gamma^+(P, \mu)$ of Definition 8.3.4 are realized as submodules of $\prod_x W_x$ Chapter10/SectionFunctorLinear2021 · EpStrongBundle.sectionSpace Chapter10/SectionFunctorLinear2021 · EpStrongBundle.plusSectionSpace. *Step 2.* Pull-back and push-forward are additive and homogeneous pointwise, for all sections, without functoriality Chapter10/SectionFunctorLinear2021 · EpStrongBundle.IsStrongBundleEquivalence.pullback_sectionAdd Chapter10/SectionFunctorLinear2021 · EpStrongBundle.IsStrongBundleEquivalence.pushforward_sectionAdd Chapter10/SectionFunctorLinear2021 · EpStrongBundle.IsStrongBundleEquivalence.pushforward_

sectionSmul, hence along diagrams and classes Chapter10/SectionFunctorLinear2021 · SBLocalization.GenSBMap.pushforward_sectionAdd. *Step 3.* With the bijections of Theorem 10.5.4, $[D]_*$ is a linear isomorphism with inverse $[D]^*$ Chapter10/SectionFunctorLinear2021 · SBLocalization.GenSBMap.pushforwardEquiv_symm_apply, and the same on Γ^+.

X.32 Propositions 10.4.6, 10.4.7 and 10.5.6 (new in 2021)

The reading of Definition 8.4.2 Chapter10/LocalizationLRBundleBase · EpStrongBundle.IsLRLocal. The text's B is a strong bundle isomorphism of $W|U(x)$ with $|B(w)| = |w|$, and the conclusion is $B(w) = g * w$. We read it for maps defined on $W|U(x)$ only, with no condition off $W|U(x)$ Chapter10/LocalizationLRBundleBase · StrongBundle.IsLocalIsoOn. Read for strong bundle maps defined on all of W, the conjugate $H^{-1} \circ B \circ H$ of the proof of Proposition 10.4.6 would not be in its scope. The local reading implies the global one Chapter10/LocalizationLRBundleBase · EpStrongBundle.IsLRLocal.isLR; we do not know whether the converse holds. The condition on one $U(x)$ is recorded separately Chapter10/StrongBundleLocalRegularity · EpStrongBundle.HasLRLocal Chapter10/StrongBundleLocalRegularity · EpStrongBundle.isLRLocal_iff_hasLRLocal.

Local isomorphisms between two bundles Chapter10/StrongBundleLocalIso · StrongBundle.IsLocalIso₂. The proofs compose local isomorphisms $Y|U \to Y'|U'$ between different bundles and invert them: inverse, composite and restriction Chapter10/StrongBundleLocalIso · StrongBundle.IsLocalIso₂.symm Chapter10/StrongBundleLocalIso · StrongBundle.IsLocalIso₂.comp Chapter10/StrongBundleLocalIso · StrongBundle.IsLocalIso₂.restrict, with the inverse linear on the fibres Chapter10/StrongBundleLocalIso · StrongBundle.IsLocalIsoOn.exists_isLocalIso₂; a strong bundle equivalence restricts to one Chapter10/StrongBundleLocalIso · StrongBundle.IsStrongBundleIsoOn.exists_isLocalIso₂. For an sc-smooth family $m(y) : y \to \tau(y)$ over U with τ an sc-diffeomorphism, $w \mapsto \mu(m(Pw), w)$ is one covering τ, with inverse $w \mapsto \mu(m(\tau^{-1}(Pw))^{-1}, w)$ Chapter10/StrongBundleLocalIso · EpStrongBundle.isLocalIso₂_lrAct Chapter10/StrongBundleLocalIso · EpStrongBundle.lrAct_comp; the natural lift of g is such a map Chapter10/StrongBundleLocalIso · EpStrongBundle.natLift_eq_lrAct.

Proposition 10.4.6 (V10.72) Chapter10/StrongBundleLocalRegularity · EpStrongBundle.proposition_10_4_6. *Step 1, the transport.* For $\psi : F(x) \to y$ and the transport chart $Q = \hat{\psi} \circ F$ of §X.5, $v \mapsto \nu(\psi_{P(v)}, \Phi(v))$, the text's $H_{\hat{\psi}} \circ \Phi$, is a local strong bundle isomorphism $V|S \to W|Q(S)$ covering Q Chapter10/StrongBundleLocalRegularity · EpStrongBundle.IsStrongBundleEquivalence.exists_transport, equivariant along $g \mapsto \psi \circ F(g) \circ \psi^{-1}$ Chapter10/StrongBundleLocalRegularity · EpStrongBundle.IsStrongBundleEquivalence.transport_Γ and preserving and reflecting orbit equality Chapter10/StrongBundleLocalRegularity · EpStrongBundle.IsStrongBundleEquivalence.π_transport_iff. *Step 2, the natural representations.* $U(y) = Q(U(x))$ with the natural action, as in Proposition 10.1.9 Chapter10/EquivalenceLR · EpFunctor.TransportChart.exists_naturalRep_push Chapter10/EquivalenceLR · EpFunctor.TransportChart.exists_naturalRep_pull. *Step 3, the conjugation.* For any such H along a surjection $G_x \to G_y$, $B \mapsto H^{-1} \circ B \circ H$ carries the orbit-preserving strong bundle isomorphisms of $W|U(y)$ to those of $V|U(x)$ and the natural lifts to the natural lifts, both ways Chapter10/StrongBundleLocalRegularity · EpStrongBundle.hasLRLocal_iff_of_equivariant. "$\Phi : W \to W$" in the statement is read $\Phi : V \to W$.

Proposition 10.4.7 (V10.73) Chapter10/StrongBundleLocalFamilies · EpStrongBundle.proposition_10_4_7 Chapter10/StrongBundleLocalFamilies · EpStrongBundle.proposition_10_4_7', with the property for the target only and $U(x)$ inside any given neighbourhood: a stronger form. *Step 1.* $|\Phi| = |\Psi|$ gives $\psi_0 : \psi(x) \to \phi(x)$; $Q = \hat{\psi}_0 \circ \psi$ and the transport $H(v) = \nu(\psi_{P(v)}, \Psi(v))$ of Proposition 10.4.6, Step 1. *Step 2.* $B = H \circ \Phi^{-1}$ is a strong bundle isomorphism of $W|U(\phi(x))$ covering $\gamma = Q \circ \phi^{-1}$, with $\gamma(U) = U$ by Lemma 7.4.20 and

$|B(w)| = |w|$ by $|\Phi| = |\Psi|$. *Step 3.* Definition 8.4.2 gives $B = k*\cdot$, so $\nu(\psi_z, \Psi(v)) = \nu(\Gamma(k, \phi(z)), \Phi(v))$ and $\alpha_z = \psi_z^{-1} \circ \Gamma(k, \phi(z))$. On the bases this is `Chapter10/LocalizationLRBundleBase · SEP.exists_family_of_isLRLocal`; the proof shows that orbit equality on the total spaces determines it on the bases `Chapter10/StrongBundleLocalFamilies · EpStrongBundle.π_base_eq_of_orbitMap_eq`. *Witness*, $\Phi = \Psi = 1$ on $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ `Chapter10/StrongBundleLocalFamilies · GapP2_GBundleFamilyExamples.proposition_10_4_7_hypotheses`.

Proposition 10.5.6 (V10.61) `Chapter10/StrongBundleLocalRegularity · SBLocalization.proposition_10_5_6`. A representative with Φ, Ψ strong bundle equivalences carries the property from W to W'' to W', by Proposition 10.4.6 twice (§X.23) (G.122, G.126).

X.33 (10.24) and the local expressions q, Q (2021 pp. 504–506)

The square (10.24) `Chapter10/StrongBundleDiagram · SBLocalization.SDiagram.square_10_24` `Chapter10/StrongBundleDiagram · SBLocalization.GenSBMap.square_10_24`. The text says the square with vertical arrows P, P' "does not make too much sense", and that with the vertical arrows replaced by "a suitable generalized map version" it commutes, leaving this to the reader. We take $i(P) = [W \xleftarrow{1} W \xrightarrow{P} X]$, with P a morphism of $\mathcal{EP}$ `Chapter10/StrongBundleDiagram · SEP.projEP`. *Step.* $P' \circ \Psi = \psi \circ P''$ on the representative, and i is a functor (Theorem 10.3.14), so $[D]_{\text{total}} \circ i(P') = i(P) \circ [d]$ in $\mathcal{EP}(E^{-1})$.

The germ q `Chapter10/StrongBundleDiagram · EPLocalization.Diagram.exists_germ_q`. For the data (x'', a, b) of γ (§X.21), q is the composite $U(x) \leftarrow U(\phi(x'')) \leftarrow U(x'') \to U(\psi(x'')) \to U(x')$ of $t \circ (s|U(a))^{-1}$, of ϕ^{-1}, of ψ and of $t \circ (s|U(b))^{-1}$. *Step 1.* A functor intertwines natural representations at u and $F(u)$ along $F : G_u \to G_{F(u)}$: both sides are sections of s agreeing at u `Chapter10/StrongBundleDiagram · EpFunctor.mor_Γ` `Chapter10/StrongBundleDiagram · EpFunctor.obj_Φ`. *Step 2.* The conjugations by a and b are equivariant for the conjugation homomorphisms `Chapter10/StrongBundleDiagram · EPLocalization.Diagram.isotropyHom_conj`. *Step 3.* Composing, $q(x) = x'$ and $q(g * z) = \gamma(g) * q(z)$ on natural representations $U(x)$, $U(x')$, the actions in which the equivariance is read.

The lift Q **and (10.25)** `Chapter10/StrongBundleDiagramLift · SBLocalization.SDiagram.exists_lift_Q`. "A strong bundle map $W|O(X, x) \to W'|O(X', x')$" is read as a local strong bundle map on $W|U(x)$, with no condition off it `Chapter10/StrongBundleDiagramLift · StrongBundle.IsLocalMap₂` `Chapter10/StrongBundleDiagramLift · StrongBundle.IsLocalMap₂.comp` `Chapter10/StrongBundleDiagramLift · StrongBundle.IsLocalIso₂.isLocalMap₂`. *Step.* $Q = H_b \circ \Psi \circ H_a^{-1}$ with the transports $H_a(v) = \mu(a_{P(v)}, \Phi(v))$ and $H_b(u) = \mu'(b_{P'(u)}, u)$ of §X.32, Step 1. It covers $q = Q_b \circ \psi \circ Q_a^{-1}$, so $P' \circ Q = q \circ P$, (10.25), and $Q(g * w) = \gamma(g) * Q(w)$ for the natural lifts (G.124). As the text says, q and Q depend on the representative.

X.34 Theorem 10.3.10 (2017: 10.4) for strong bundles: the converse

Isomorphisms of $\mathcal{SEP}(F^{-1})$ **are generalized strong bundle isomorphisms** (V10.71) `Chapter10/StrongBundleIsoConverse · SBLocalization.SEPLoc.equivalences_Ψ_of_isIso` `Chapter10/StrongBundleIsoConverse · SBLocalization.SEPLoc.isIso_homMk_iff` `Chapter10/StrongBundleIsoConverse · SBLocalization.SEPLoc.isIso_iff_isGeneralizedIso`. Remark 10.5.3 says "a similar result can be proved" and builds it into Definition 10.5.2. Let $[E] = [W' \xleftarrow{\Phi'} V'' \xrightarrow{\Psi'} W]$ be the inverse of $[D]$. *Step 1, the base.* ψ is an equivalence (§X.22). *Step 2, fibrewise injectivity from* $[D] \circ [E] = 1$. A strong bundle equivalence H into the middle $W'' \times_{W'} V''$ makes $\Psi' \circ \Pi_{V''} \circ H$ naturally equivalent

to a strong bundle equivalence Chapter10/StrongBundleIsoConverse · SBLocalization.SDiagram.exists_natEquiv_of_equiv. Since $\Pi_{V''}(m)$ is determined by $\Psi(\Pi_{W''}(m))$, Ψ is injective on the fibres over the points $\Pi_{W''}(H(c))$, and on all fibres by transport along morphisms Chapter10/StrongBundleIsoConverse · SEP.FibInj Chapter10/StrongBundleIsoConverse · SBLocalization.SDiagram.fibInj_Ψ_of_equiv. *Step 3, a natural equivalence from* $[E]\circ[D] = 1$. Likewise $\Psi \circ G$ is naturally equivalent to a strong bundle equivalence K for $G = \Pi_{W''} \circ H$. *Step 4, local inverses.* For x choose $\gamma : g(c) \to x$. The transport along γ gives $G' = H_{\hat{\gamma}} \circ G$ (§X.32), and $\Psi \circ G'$ is the transport of K, a local strong bundle isomorphism near c. So $G' \circ (\Psi \circ G')^{-1}$ is a local right inverse of Ψ near $\psi(x)$, at levels $[0]$ and $[1]$. With the fibrewise injectivity and the local injectivity of ψ, Ψ is a strong bundle isomorphism near x Chapter10/StrongBundleIsoConverse · SEP.isStrongBundleIsoOn_of_rightInv Chapter10/StrongBundleIsoConverse · SEP.exists_isStrongBundleIsoOn, and on morphisms through the pull-back projections Chapter10/StrongBundleIsoConverse · SEP.isLocalStrongBundleIso_mor_of_obj. *Step 5, the total space and* $|W[1]|$. The total functor is full Chapter10/StrongBundleIsoConverse · SEP.full_total and an equivalence by Lemma 10.1.2 Chapter10/StrongBundleIsoConverse · SEP.isEquivalence_total. $|\Psi|$ on $|W''[1]|$ is a continuous bijection with the continuous inverse $|G| \circ |K|^{-1}$ Chapter10/StrongBundleIsoConverse · SEP.NatEquiv.oneOrbitMap_eq Chapter10/StrongBundleIsoConverse · SEP.isHomeomorph_oneOrbitMap_of. Together, the saturation step Chapter10/StrongBundleIsoConverse · SEP.equivalences_of_natEquiv_comp: a strong bundle functor covering an equivalence, injective on fibres, with $\Psi \circ G \simeq K$ for a strong bundle equivalence K, is a strong bundle equivalence. This replaces the claims (C1), (C2) of Appendix §10.6.2, which the text does not restate for strong bundles (G.123).

Part XI. Geometry up to equivalences (HWZ Chapter 11, §§11.1–11.6 (2017 §§11.1–11.6))

Chapter 11 closes the ep-groupoid half of Part II; its numbers and pages are those of the book (Springer 2021, pp. 521–566), with the 2017 text's in parentheses (2017 pp. 375–416). It asks which of the notions built on ep-groupoids in Chapters 8 and 9 survive the passage to $\mathcal{EP}(E^{-1})$ of Chapter 10, where generalized isomorphisms are the isomorphisms. §11.1 extends the tangent functor (Theorem 11.1.1 (2017: 11.1)), shows that the degeneracy index is invariant (Proposition 11.1.2 (2017: 11.1)) and treats faces (Definition 11.1.3, Example 11.1.4, Remark 11.1.5, Proposition 11.1.6, Remark 11.1.7, Proposition 11.1.8 (2017: Definition 11.1, Example 11.1, Remark 11.1, Proposition 11.2, Remark 11.2, Proposition 11.3)). §11.2 does the same for sc-differential forms (Theorem 11.2.1 to Proposition 11.2.9 (2017: Theorem 11.2 to Proposition 11.5)). §11.3 pushes forward and pulls back functors $\Theta : X \to \mathbb{Q}^+$ (Definition 11.3.1, Lemma 11.3.2, Theorem 11.3.3 (2017: Definition 11.4, Lemma 11.5, Theorem 11.3)) and continues with the bundles of tangent sets and orientations (Lemma 11.3.4 to Theorem 11.3.9 (2017: Lemma 11.6 to Theorem 11.7)). §11.4 transforms the canonical measures (Theorems 11.4.1, 11.4.2, 11.4.4, 11.4.5, Remark 11.4.3 (2017: Theorems 11.8, 11.9, Remark 11.3)). §11.5 carries auxiliary norms and sc$^+$-multisections along generalized strong bundle isomorphisms (Proposition 11.5.1, Lemma 11.5.2, Proposition 11.5.3 (2017: Proposition 11.6, Lemma 11.7, Proposition 11.7)). §11.6 studies proper covering functors up to equivalence (Lemmas 11.6.1–11.6.3, Definitions 11.6.4, 11.6.5, 11.6.7, Theorem 11.6.6, Proposition 11.6.8, Remark 11.6.9 (2017: Lemmas 11.8, 11.9, Definitions 11.6–11.8, Theorem 11.10, Proposition 11.8, Remark 11.4); Lemma 11.6.1 is new in the 2021 edition).

What is proved, and what is not. All eight gaps of Chapter 11 are closed (G.128–G.135). None is set aside as having nothing to formalize. *§11.1.* Theorem 11.1.1, Proposition 11.1.2, Definition 11.1.3, Example 11.1.4 (for $[0,\infty)^2 \oplus W$ with any W), Remark 11.1.5 (with the result it quotes), Remark 11.1.7 and Proposition 11.1.8 are proved (§§XI.1–XI.3). Proposition 11.1.6 is proved except for its intersection clause, which does not hold as we read it and holds in a union form (§§XI.3, XI.19, XI.20; G.128): the faces of a face structured tame ep-groupoid are tame ep-groupoids, and a generalized isomorphism induces generalized isomorphisms $[d]_F$ of faces. *§11.2.* All of it is proved: Theorem 11.2.1, Lemmas 11.2.2, 11.2.4–11.2.6, Definitions 11.2.3, 11.2.7, (11.5) and Propositions 11.2.8, 11.2.9 (§XI.4; G.129). *§11.3.* Proved: Definition 11.3.1, Lemma 11.3.2 in a stronger form, the push-forward and pull-back along generalized maps, and all six parts of Theorem 11.3.3, (6) for every dimensional decomposition (§§XI.5–XI.7). Also proved: Lemma 11.3.4 with (11.8) and (11.9), Theorem 11.3.5, Definition 11.3.6 with (11.10), and Theorems 11.3.7 and 11.3.8, whose proofs the text leaves to the reader (§XI.8). They were first proved under

Chapter 9's hypothesis that the tangent sums of Theorem 9.2.1 are independent, which Chapter 9 now proves for every Θ. Theorem 11.3.9 is proved for the intrinsic boundary orientation of Definition 9.3.10, independently of the representative and with no hypothesis (§XI.8; G.130). *§11.4.* Formalized (§XI.9; G.131). Theorems 11.4.1 and 11.4.2 and Remark 11.4.3 are proved, with no added hypothesis, for the canonical measures of Chapter 9 built from its concrete sheet integrals. Theorems 11.4.4 and 11.4.5 are proved with the text's hypotheses, for every $n \geq 1$, for the boundary measures of Theorems 9.5.15 and 9.5.16. *§11.5.* Proposition 11.5.1 is proved with conditions (1) and (2) of Definition 8.3.5 (§XI.10; G.132), and Lemma 11.5.2 and Proposition 11.5.3 for sc$^+$-multisections with their local section structures (§XI.11; G.133). *§11.6.* Proved: Lemmas 11.6.1–11.6.3, Definitions 11.6.4, 11.6.5, 11.6.7, all claims of Theorem 11.6.6 and Proposition 11.6.8 (§§XI.12–XI.15). Also proved: the localization $\mathcal{PC}(E^{-1})$ with I (§XI.21; G.134), and the category of proper strong bundle coverings of Remark 11.6.9 with its localization (§XI.22; G.135), both sketched in the text with the details left to the reader. *The narrower row.* V11.6, Proposition 11.1.6: the clause that two faces meet in a face of each does not hold as we read it. The Lean counterexample is `FaceMeetExample.not_facesMeetInFaces`, two faces of $([0,\infty)^3 \oplus W) \setminus K$ meeting in two pieces of an edge. What is proved is that they meet in a union of faces of each (§XI.20). V11.29, Theorems 11.4.4 and 11.4.5, is restated: the class hypothesis `hcov` is derived in Chapter 9 and $n = 1$ is covered (§XI.9).

Six structural choices. (1) *Faces by their object sets.* A face X_θ of X is the saturated set $\pi^{-1}(\theta)$ with the morphisms whose source lies in it; the faces of $|X|$ are Chapter 2's faces for the index $d_{|X|}$ on the open set $|X|$, so Chapter 2's lemmas on faces apply to them (§XI.2). (2) *Total push-forwards.* $F_*\Theta$ is defined for every sc-smooth functor and every map on objects, with one choice of x and of a morphism $F(x) \to y$, and 0 where there is none; the statements say when the choice does not matter (§XI.5). (3) *Classes through representatives.* f_* and f^* on $\mathcal{EP}(E^{-1})$ are computed on a chosen representative with an equivalence as left leg (`rep`), and shown independent of it (§XI.6). (4) *Multisections as functors.* A multisection functor on a strong bundle is a map on the total object space constant along the morphisms of the total ep-groupoid; the local section structures of Definition 13.2.1 are a predicate on top of it (§XI.11). (5) *Functors of proper coverings as pairs.* A functor $F \to F'$ is a structure with the two functors and the two commutation equations, on objects and on morphisms, and $\mathcal{PC}$ is a category with composition associative on the nose (§§XI.13, XI.15). (6) *Sections and boundary operations.* Section functors of $\widehat{Gr}$ are functions on all objects, 0 off X_∞; Chapter 9's boundary lift depends on a boundary operation given as data, so Theorem 11.3.9 is first proved for a representative under a hypothesis relating the boundary operations on the two sides, and then, for the intrinsic boundary orientation of Definition 9.3.10, with no hypothesis (§XI.8).

Map.

- `Chapter11/BoundaryMeasureTextHypotheses`: Theorems 11.4.4 and 11.4.5 with the text's hypotheses, $n \geq 2$; `Chapter11/BoundaryMeasureEquivalenceDimOne`, `BoundaryMeasureGeneralizedIsoDimOne`: the same for $n = 1$ (§XI.9).

XI.1 Theorem 11.1.1 (2017: 11.1): the tangent functor on $\mathcal{EP}(E^{-1})$

The tangent of a diagram (V11.1) `Chapter11/EpEquivalenceGeometry · EPLocalization.Diagram.tangent`. For $d = [X \xleftarrow{F} A \xrightarrow{\Phi} Y]$ the diagram $Td = [TX \xleftarrow{TF} TA \xrightarrow{T\Phi} TY]$; TF is an equivalence by Theorem 10.1.7. Chapter 8's functoriality of T is used in the form $T(G \circ F) = TG \circ TF$ `Chapter11/EpEquivalenceGeometry · EpFunctor.tangent_comp` and $T1 = 1$ `Chapter11/EpEquivalenceGeometry · EpFunctor.tangent_`

id. *Step 1, refinements.* A refinement $H : d' \to d$ with natural transformations $\sigma : F' \to F \circ H$, $\tau : \Phi' \to \Phi \circ H$ gives TH with $T\sigma$, $T\tau$ (Proposition 8.1.14), so $TH : Td' \to Td$ is a refinement Chapter11/EpEquivalenceGeometry · EPLocalization.Diagram.IsRefinement.tangent, and equivalent diagrams have equivalent tangents Chapter11/EpEquivalenceGeometry · EPLocalization.Diagram.Equiv.tangent; this is the argument of the text. *Step 2, identities.* T of the identity diagram refines the identity diagram of TX Chapter11/EpEquivalenceGeometry · EPLocalization.Diagram.isRefinement_tangent_id. *Step 3, composition, left to the reader.* For functors $P : C \to X$, $Q : C \to Z$ and a natural transformation $\Phi \circ P \to G \circ Q$, $c \mapsto (P(c), \tau(c), Q(c))$ is a functor into the weak fibred product Chapter11/EpEquivalenceGeometry · EPLocalization.wfpLift with the right projections Chapter11/EpEquivalenceGeometry · EPLocalization.projLeft_comp_wfpLift Chapter11/EpEquivalenceGeometry · EPLocalization.projRight_comp_wfpLift. Applied to $T\pi_A$, $T\pi_B$ and T of the transformation of $A \times_Y B$, it gives $T(A \times_Y B) \to TA \times_{TY} TB$; its composite with the projection to TA is the equivalence $T\pi_A$, so it is an equivalence by two out of three, and it refines $Td \circ Te$ by $T(d \circ e)$ Chapter11/EpEquivalenceGeometry · EPLocalization.Diagram.isRefinement_tangent_comp. *Step 4, the functor.* `tangentFunctor` on classes Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.tangentFunctor Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.tangentFunctor_obj Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.tangentFunctor_map_homMk, compatible with the localization functor Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.tangentFunctor_map_localizationFunctor; it maps generalized isomorphisms to generalized isomorphisms Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.isGeneralizedIso_tangent. **Theorem 11.1.1** Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.theorem_11_1_1 collects these.

XI.2 Proposition 11.1.2 (2017: 11.1), Definition 11.1.3 (2017: 11.1) and Example 11.1.4 (2017: 11.1)

Proposition 11.1.2 (2017: 11.1) (V11.2) Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.proposition_11_1_2. *Step 1, equivalences.* An equivalence is a local sc-diffeomorphism on objects, and a local sc-diffeomorphism preserves the degeneracy index, so $d_Y(F(x)) = d_X(x)$, and d is constant on orbits Chapter11/EpEquivalenceGeometryFaces · EpFunctor.IsEquivalence.degIndexOrbit_orbitMap Chapter7/EpGroupoid · EpGroupoid.degIndexOrbit. *Step 2, diagrams.* For a diagram with both legs equivalences, $|d| = |\Phi| \circ |F|^{-1}$ preserves $d_{|\cdot|}$ Chapter11/EpEquivalenceGeometry · EPLocalization.Diagram.degIndexOrbit_orbitMap. *Step 3, classes.* A generalized isomorphism has such a representative (Theorem 10.3.10; the proof says "Proposition 10.3.10", a possible misprint) Chapter11/EpEquivalenceGeometry · EPLocalization.EPLoc.degIndexOrbit_orbitMap.

Definition 11.1.3 (2017: 11.1) (V11.3) Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.IsOrbitFace Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.faceObj Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.faceMor Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.IsEpFace Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.IsEpFaceStructured Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.IsWeaklyFaceStructured. The object set of X_θ is saturated Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.isSaturated_faceObj and its morphisms are those between its objects Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.faceMor_eq. A face of $|X|$ is exactly a face, in Chapter 2's sense, of the open set $|X|$ for the index $d_{|X|}$ Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.isOrbitFace_iff_isFaceIn, so the faces through z Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.orbitFacesThrough are Chapter 2's Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.orbitFacesThrough_eq and face-structuredness is Chapter 2's condition for $|X|$ Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.isEpFaceStructured_iff. The number of faces through z is counted in $\mathbb{N} \cup \{\infty\}$, so that infinitely many faces do not count as 0.

Example 11.1.4 (2017: 11.1) (V11.4) Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.Examples.example_11_1_4. *The trivial groupoid.* With only identities, π is a homeomorphism Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.Examples.isHomeomorph_π_trivial and the face structure of $C = [0,\infty)^2 \oplus W$ is that of the quadrant Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.Examples.isFaceStructured_quadrant. *The swap.* $\mathbb{Z}/2 \ltimes C$ with -1 exchanging the two coordinates Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.Examples.swapEpGroupoid; its object M-polyfold is C, face structured. In $|X|$ the set $\{d_{|X|} = 1\}$ is the image of one connected stratum, since the swap identifies the two open half-axes Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.Examples.setOf_degIndexOrbit_eq_one_swap; $|X|$ has exactly one face Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.Examples.isOrbitFace_swap_iff, and $|0|$, of index 2, lies in one face only Chapter11/EpEquivalenceGeometryFaces · EpGroupoid.Examples.not_isEpFaceStructured_swap. The text gives no reason; this is it.

XI.3 Remark 11.1.5 (2017: 11.1), Proposition 11.1.6 (2017: 11.2), Remark 11.1.7 (2017: 11.2), Proposition 11.1.8 (2017: 11.3)

The quoted result (V11.5). The text quotes [56, Proposition 3.15] for the fact that faces correspond under a homeomorphism preserving the index. For the faces of Chapter 2 on open sets: such a homeomorphism maps faces to faces Chapter11/EpEquivalenceGeometryFaces · TameBoundary.isFaceIn_univ_image, every face is the image of one Chapter11/EpEquivalenceGeometryFaces · TameBoundary.exists_isFaceIn_univ_preimage, the orbit map of an equivalence is such a homeomorphism Chapter11/EpEquivalenceGeometryFaces · TameBoundary.isDHomeoOn_univ, and face-structuredness transfers Chapter11/EpEquivalenceGeometryFaces · TameBoundary.isFaceStructuredOpen_univ_iff. *Equivalences.* $|\Phi|$ induces the bijection of faces Chapter11/EpEquivalenceGeometryFaces · EpFunctor.IsEquivalence.bijOn_faces, with $\Phi_*(X_\theta) = \text{saturation}(\Phi(X_\theta)) = Y_{|\Phi|(\theta)}$ Chapter11/EpEquivalenceGeometryFaces · EpFunctor.saturation_image_faceObj and $\Phi^{-1}(Y_{\theta'}) = X_{|\Phi|^{-1}(\theta')}$ Chapter11/EpEquivalenceGeometryFaces · EpFunctor.preimage_faceObj. *Generalized isomorphisms.* $||[d]||$ is a homeomorphism Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.isHomeomorph_orbitMap; `faceMap` and `faceComap` are the image and preimage of faces Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.faceMap Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.faceComap, computed on a representative as $\Psi_* \circ \Phi^*$ and $\Phi_* \circ \Psi^*$ Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.faceMap_homMk Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.faceComap_homMk, and mutually inverse bijections Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.bijOn_faceMap. **Remark 11.1.5** Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.remark_11_1_5.

Proposition 11.1.6 (2017: 11.2), the part on $[d]_*$ (V11.6) Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.proposition_11_1_6. $[d]_*$ and $[d]^*$ map faces to faces Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.isOrbitFace_faceMap Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.isOrbitFace_faceComap and are inverse Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.faceComap_faceMap Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.faceMap_faceComap; $||[d]||$ restricts to homeomorphisms $\theta \to [d]_*\theta$. No face structure is used. The faces as tame ep-groupoids and the generalized isomorphisms $[d]_F$ are §XI.19, and the intersection clause §XI.20 (G.128, closed).

Remark 11.1.7 (2017: 11.2) (V11.7) Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.remark_11_1_7. Chapter 10 transfers tameness from Y to X along an equivalence Chapter10/WeakFibredProductTheorem · EpFunctor.IsEquivalence.isTame_of_isTame. The converse goes through $X \times_Y Y$ for F and 1_Y: its projection to X is an equivalence, so $X \times_Y Y$ is tame by Chapter 10's direction, and its projection to Y is a surjective local sc-diffeomorphism on objects, by the essential surjectivity

of F, which carries tameness down Chapter11/EpEquivalenceGeometryFaces · EpFunctor.IsEquivalence.isTame_of_isTame_left Chapter11/EpEquivalenceGeometryFaces · EpFunctor.IsEquivalence.isTame_iff. With §XI.2 and the transfer of face-structuredness above, a generalized isomorphism preserves "tame and face structured" both ways.

Proposition 11.1.8 (2017: 11.3) (V11.8) Chapter11/EpEquivalenceGeometryFaces · EPLocalization.EPLoc.proposition_11_1_8. f_* and f^* depend only on $|f|$, by their definition as image and preimage; on a face, $|f|$ and $|g|$ agree. The text's maps $|F| \to |f_*F|$ come from the generalized isomorphisms of (11.1). They are the restrictions of $|f|$, and the second claim, for the generalized isomorphisms $[f]_F$ themselves, is §XI.19 Chapter11/FaceGeneralizedIso · EPLocalization.EPLoc.proposition_11_1_8_faceIso.

XI.4 §11.2: sc-differential forms (Theorem 11.2.1 to Proposition 11.2.9 (2017: Theorem 11.2 to Proposition 11.5))

§11.2 is formalized (G.129), for Chapter 8's forms Ω^k_{ep} of an ep-groupoid and their direct limit $\Omega^*_{ep,\infty}$ over the index lifts X^i. The pattern is that of §11.3: a push-forward along equivalences by a choice of x and $\psi : F(x) \to y$ that does not matter, composition rules, invariance under refinements, and generalized maps through $F_* \circ G^*$. The formal route differs in one point: F_* is defined as the inverse of F^*, and the text's defining formula becomes a theorem.

Descent along a surjective local sc-diffeomorphism. For M-polyfolds and a surjective local sc-diffeomorphism $q : X \to Y$, the tangent spaces of Y are images Chapter11/FormDescent · MPolyfold.IsLocalScDiffeo.exists_tangentFiber_lift, so q^* is injective on families of alternating forms Chapter11/FormDescent · MPolyfold.formPullback_injective_of_isLocalScDiffeo. A family τ on Y with $q^*\tau$ an sc-form is an sc-form: on the image V of a sheet of q, with inverse g, $\tau|V = g^*(q^*\tau)$, the text's (11.4), and sc-smoothness of a form is local Chapter11/FormDescent · MPolyfold.isScForm_of_formPullback. A family η on X taking the same values on vectors with the same image under Tq descends, $\tau_y = \eta_x \circ (Tq(x))^{-1}$, with $q^*\tau = \eta$ Chapter11/FormDescent · MPolyfold.formDescend Chapter11/FormDescent · MPolyfold.formPullback_formDescend.

Lemma 11.2.2 and Definition 11.2.3 (2017: Lemma 11.1, Definition 11.2) (V11.10). *Step 1, the full case.* For F full and a local sc-diffeomorphism on objects, a form of the ep-groupoid X takes the same values on vectors over x, x' with $F(x) = F(x')$ and the same images under TF, since a morphism $x \to x'$ exists and forms of ep-groupoids are invariant under morphisms; if F is also surjective on objects, every form on X descends to a form τ on Y with $F^*\tau$ the given one Chapter11/EquivalenceForms · EpFunctor.exists_epForms_formPullback_eq_of_surjective. *Step 2, equivalences, through the weak fibred product.* For an equivalence F, $A = X \times_Y Y$ of F and 1_Y has the objects (x, ψ, y), $\psi : F(x) \to y$, of the text's definition; $\pi_Y : A \to Y$ is an equivalence surjective on objects and $F \circ \pi_X \simeq \pi_Y$. Pull-backs compose Chapter11/EquivalenceForms · EpFunctor.formPullback_comp_functor, and F^* is injective Chapter11/EquivalenceForms · EpFunctor.IsEquivalence.injOn_formPullback and onto, $F_*\omega$ being the descent of $\pi_X^*\omega$ along π_Y Chapter11/EquivalenceForms · EpFunctor.IsEquivalence.exists_formPullback_eq. So $F^* : \Omega^k_{ep}(Y) \to \Omega^k_{ep}(X)$ is bijective Chapter11/EquivalenceForms · EpFunctor.IsEquivalence.bijective_formPullback, and F_* is its inverse Chapter11/EquivalenceForms · EpFunctor.IsEquivalence.formPush. *Step 3, the text's formula.* $(F_*\omega)_y(T\psi(TF(x)l_1), \dots, T\psi(TF(x)l_k)) = \omega_x(l_1, \dots, l_k)$ for every x, $\psi : F(x) \to y$ and $l_j \in T_xX$ Chapter11/EquivalenceForms · EpFunctor.IsEquivalence.definition_11_2_3, and every $h_1, \dots, h_k \in T_yY$ is of this form Chapter11/EquivalenceForms · EpFunctor.IsEquivalence.exists_lift_tangent, so the formula determines $F_*\omega$. *Step 4, Lemma 11.2.2* Chapter11/EquivalenceForms · EpFunctor.IsEquivalence.lemma_11_2_2: both sides equal $(F_*\omega)_y(h_1, \dots, h_k)$. Before Definition 11.2.3 the text's $\Omega(X)$ for the target is read $\Omega(Y)$.

Lemmas 11.2.4–11.2.6 (2017: 11.2–11.4) and (11.5) (V11.11). *Step 1, levels.* The index raises $F^i : X^i \to Y^i$ of an equivalence are equivalences (Chapter 10) Chapter11/EquivalenceFormsInfty · EP.isEquivalence_liftFunctor, so F_* exists on each level Chapter11/EquivalenceFormsInfty · EP.epFormsPush and commutes with the maps of the directed system; this gives F_* on $\Omega^k_{ep,\infty}$ Chapter11/EquivalenceFormsInfty · EP.epFormsInftyPush, inverse to F^* Chapter11/EquivalenceFormsInfty · EP.epFormsInftyPullback_comp_epFormsInftyPush Chapter11/EquivalenceFormsInfty · EP.epFormsInftyPush_comp_epFormsInftyPullback, Lemma 11.2.4 (3). *Step 2, (11.5).* $d_Y \circ F_* = F_* \circ d_X$, from d commuting with F^* and $F_* = (F^*)^{-1}$ Chapter11/EquivalenceFormsInfty · EP.epFormsInftyD_comp_epFormsInftyPush. *Step 3, Lemma 11.2.4 (1), (2).* $(G \circ F)^* = F^* \circ G^*$ is Chapter 8's Chapter8/EpFormsFunctor · EP.epFormsInftyPullback_comp, and inverting it gives $(G \circ F)_* = G_* \circ F_*$ Chapter11/EquivalenceFormsInfty · EP.lemma_11_2_4_two. *Step 4, Lemma 11.2.5.* Naturally equivalent functors have the same pull-back (Chapter 8) Chapter8/EpFormsFunctor · EP.epFormsInftyPullback_eq_of_natTrans; F_* is the only right inverse of F^* Chapter11/EquivalenceFormsInfty · EP.epFormsInftyPush_eq_of_comp_eq_id, so naturally equivalent equivalences have the same push-forward Chapter11/EquivalenceFormsInfty · EP.lemma_11_2_5_push. *Step 5, Lemma 11.2.6.* For $H : A' \to A$ with $F \circ H \simeq F'$ and $G \circ H \simeq G'$: $F_*G^* = F_*H_*H^*G^* = (F \circ H)_*(G \circ H)^* = F'_*G'^*$ by Steps 3 and 4 Chapter11/EquivalenceFormsInfty · EP.lemma_11_2_6, and the same for G_*F^* Chapter11/EquivalenceFormsInfty · EP.lemma_11_2_6_push. In the proof of Lemma 11.2.6 the text's "Lemma 11.2.2 and 11.2.3" is read as Lemmas 11.2.4 and 11.2.5.

Definition 11.2.7 (2017: 11.3) and Theorem 11.2.1 (1)–(3) (2017: 11.2) (V11.12, V11.9). *Step 1, diagrams.* $d^* = F_* \circ \Phi^*$ and, for Φ an equivalence, $d_* = \Phi_* \circ F^*$ Chapter11/GeneralizedForms · EPLocalization.Diagram.formsPullback Chapter11/GeneralizedForms · EPLocalization.Diagram.formsPush. They are unchanged under refinement by Lemma 11.2.6 Chapter11/GeneralizedForms · EPLocalization.Diagram.formsPullback_eq_of_isRefinement, hence on equivalent diagrams Chapter11/GeneralizedForms · EPLocalization.Diagram.formsPullback_eq_of_equiv Chapter11/GeneralizedForms · EPLocalization.Diagram.formsPush_eq_of_equiv. *Step 2, composites.* A base change square in the weak fibred product Chapter11/GeneralizedForms · EP.epFormsInftyPush_epFormsInftyPullback_of_square gives the pull-back of the composite diagram Chapter11/GeneralizedForms · EPLocalization.Diagram.formsPullback_comp. *Step 3, classes.* f^* for every generalized map, equal to $F_* \circ \Phi^*$ on every representative Chapter11/GeneralizedForms · EPLocalization.EPLoc.formsPullback Chapter11/GeneralizedForms · EPLocalization.EPLoc.formsPullback_homMk, with $(g \circ f)^* = f^* \circ g^*$ Chapter11/GeneralizedForms · EPLocalization.EPLoc.formsPullback_comp, so $\Omega^k_{ep,\infty}$ is a contravariant functor on $\mathcal{EP}(E^{-1})$, beyond the text. For a generalized isomorphism with inverse g, $h_* = g^*$ Chapter11/GeneralizedForms · EPLocalization.EPLoc.formsPush, which by Theorem 10.3.10 is $\Phi_* \circ F^*$ on every representative Chapter11/GeneralizedForms · EPLocalization.EPLoc.formsPush_homMk, the text's definition. *Step 4, Theorem 11.2.1.* (1) $d \circ d = 0$ Chapter11/GeneralizedForms · EPLocalization.EPLoc.theorem_11_2_1_one; (2) $d_X \circ f^* = f^* \circ d_Y$ from (11.5) and Chapter 8 Chapter11/GeneralizedForms · EPLocalization.EPLoc.theorem_11_2_1_two; (3) $h_* \circ d_X = d_Y \circ h_*$, $h_* \circ h^* = 1$, $h^* \circ h_* = 1$ Chapter11/GeneralizedForms · EPLocalization.EPLoc.theorem_11_2_1_three.

Propositions 11.2.8 and 11.2.9 (2017: 11.4 and 11.5), Theorem 11.2.1 (4) (V11.13). *Step 1, local families.* The conclusion of Proposition 10.1.10 (1), an sc-smooth $z \mapsto \alpha_z : F(z) \to G(z)$ near every object Chapter11/OrbitForms · EpFunctor.HasLocalNatIso, holds for equivalences with $|F| = |G|$ when X or Y has the local regularity property Chapter11/OrbitForms · EpFunctor.hasLocalNatIso_of_orbitMap_eq, and passes to level 1 and to the index raises Chapter11/OrbitForms · EpFunctor.HasLocalNatIso.liftOne. *Step 2, the pull-backs agree.* Locally $F = s \circ \alpha$ and $G = t \circ \alpha$, and $s^*\omega = t^*\omega$ for a form of the ep-groupoid Y, so $F^*\omega = G^*\omega$ Chapter11/OrbitForms · EpFunctor.HasLocalNatIso.formPullback_eq Chapter11/OrbitForms · EP.epFormsInftyPullback_eq_of_orbitMap_eq. The text's second computation for $F_* = G_*$ is replaced by inverting. **Proposition 11.2.8** Chapter11/OrbitForms · EP.proposition_11_2_8. *Step 3, generalized isomorphisms.* As in the text, through the weak

fibred product $A \times_X A'$: Proposition 11.2.8 applies to the equivalences $G \circ \pi_A$ and $G' \circ \pi_{A'}$, where the property of Y suffices by Proposition 10.1.9 `Chapter11/OrbitForms · EPLocalization.EPLoc.formsPullback_eq_of_orbitMap_eq`. **Proposition 11.2.9** `Chapter11/OrbitForms · EPLocalization.EPLoc.proposition_11_2_9` and **Theorem 11.2.1 (4)** `Chapter11/OrbitForms · EPLocalization.EPLoc.theorem_11_2_1_four`. The hypotheses are the text's; the local regularity property of the lifts X^i is neither assumed nor needed, the families of Step 1 being restricted to the levels. The property is satisfiable, by the point and by $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ (Chapter 10).

XI.5 Definition 11.3.1 (2017: 11.4) and Lemma 11.3.2 (2017: 11.5)

Definition 11.3.1 (2017: 11.4) (V11.14) `Chapter11/BranchedEquivalence · EpFunctor.pullbackTheta` `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta`. $F^*\Theta' = \Theta' \circ F$ `Chapter11/BranchedEquivalence · EpFunctor.pullbackTheta_apply`. $F_*\Theta(y)$ is Θ at a chosen x with $F(x) \cong y$, and 0 if there is none `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_of_not_exists`; a nonzero value implies the existence `Chapter11/BranchedEquivalence · EpFunctor.exists_isomorphic_of_pushforwardTheta_ne_zero`, and nonnegativity is kept `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_nonneg`. The text writes the push-forward as a map $X' \to \mathbb{Q}^+$; we read $Y \to \mathbb{Q}^+$ (possible misprint).

Lemma 11.3.2 (2017: 11.5) (V11.15). *Step 1, the choice does not matter.* Functors are constant on isomorphism classes `Chapter11/BranchedEquivalence · EpGroupoid.IsFunctorial.eq_of_isomorphic`. If F is full and $F(x) \cong y \cong F(x')$, then $F(x) \cong F(x')$ `Chapter11/BranchedEquivalence · EpFunctor.isomorphic_obj` lifts to $x \cong x'$ `Chapter11/BranchedEquivalence · EpFunctor.isomorphic_of_full`, so $F_*\Theta(y) = \Theta(x)$ for every such x `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_eq` `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_obj` `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_eq_of_isomorphic`; this is the text's argument with σ lifting $\psi^{-1} \circ \psi'$. *Step 2, functors.* $F_*\Theta$ is a functor for full F `Chapter11/BranchedEquivalence · EpFunctor.isFunctorial_pushforwardTheta`, $F^*\Theta'$ for every F `Chapter11/BranchedEquivalence · EpFunctor.isFunctorial_pullbackTheta`. *Step 3, (1) and (2).* $F^*F_*\Theta = \Theta$ for full F `Chapter11/BranchedEquivalence · EpFunctor.pullbackTheta_pushforwardTheta`; $F_*F^*\Theta' = \Theta'$ for essentially surjective F `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_pullbackTheta`. *Step 4, (3).* Naturally equivalent full functors have equal push-forwards `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_eq_of_naturallyEquivalent`, naturally equivalent functors equal pull-backs `Chapter11/BranchedEquivalence · EpFunctor.pullbackTheta_eq_of_naturallyEquivalent`. *Step 5, composition.* $(G \circ F)^* = F^* \circ G^*$ `Chapter11/BranchedEquivalence · EpFunctor.pullbackTheta_comp`, $(G \circ F)_* = G_* \circ F_*$ for full functors `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_comp`, $1_* = 1$ `Chapter11/BranchedEquivalence · EpFunctor.pushforwardTheta_id`.

XI.6 The push-forward and pull-back along generalized maps, pp. 536–537

Diagrams (V11.16) `Chapter11/BranchedEquivalenceLocalization · EPLocalization.Diagram.pushTheta` `Chapter11/BranchedEquivalenceLocalization · EPLocalization.Diagram.pullTheta`. For $d = [X \xleftarrow{F} A \xrightarrow{\Phi} Y]$, $d_* = \Phi_* F^*$ and $d^* = F_*\Phi^*$. *Step 1, refinements.* For a refinement $H : d' \to d$, H is an equivalence and $F' \simeq F \circ H$, $\Phi' \simeq \Phi \circ H$; Lemma 11.3.2 (3) and the composition rules give $d'^* = d^*$, and $d'_* = d_*$ when Φ is an equivalence, which then holds for Φ' as well `Chapter11/BranchedEquivalenceLocalization · EPLocalization.Diagram.IsRefinement.isEquivalence_Φ_iff` `Chapter11/BranchedEquivalenceLocalization · EPLocalization.Diagram.pullTheta_eq_of_isRefinement` `Chapter11/`

BranchedEquivalenceLocalization · EPLocalization.Diagram.pushTheta_eq_of_isRefinement. *Step 2, equivalent diagrams* have a common refinement Chapter11/BranchedEquivalenceLocalization · EPLocalization.Diagram.pullTheta_eq_of_equiv Chapter11/BranchedEquivalenceLocalization · EPLocalization.Diagram.pushTheta_eq_of_equiv.

Classes. A chosen representative Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.rep Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.homMk_rep Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.equiv_rep_homMk, with an equivalence as right leg for a generalized isomorphism Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.isEquivalence_rep_Φ, defines f^* for every generalized map and f_* for generalized isomorphisms Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pullTheta Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pushTheta, computed on any representative Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pullTheta_homMk Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pushTheta_homMk, and mapping functors to functors Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.isFunctorial_pullTheta Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.isFunctorial_pushTheta. *Composition, "easily verified" in the text.* The composite of $[d]$ and $[e]$ is represented through the weak fibred product $A \times_Y B$ (Theorem 10.3.8). In it, Θ satisfies base change: $(\pi_B)_*(\pi_A)^*\Theta = G^*F_*\Theta$ when F is an equivalence, and symmetrically Chapter11/BranchedEquivalenceLocalization · WeakFibredProduct.pushforwardTheta_projRight_pullbackTheta Chapter11/BranchedEquivalenceLocalization · WeakFibredProduct.pushforwardTheta_projLeft_pullbackTheta; the proof evaluates both sides at (a, ψ, b) and uses that a functor Θ takes equal values on isomorphic objects. Hence $(f \gg g)^* = f^* \circ g^*$ for all generalized maps Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pullTheta_comp and $(f \gg g)_* = g_* \circ f_*$ for generalized isomorphisms Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pushTheta_comp, with $(f^{-1})_* = f^*$ Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pushTheta_inv and the inverse laws Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pullTheta_pushTheta Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pushTheta_pullTheta. Nothing here uses Theorem 10.3.19, which does not hold as we read it (Chapter 10).

XI.7 Theorem 11.3.3 (2017: 11.3)

Moving a local branching structure (V11.17). Given an sc-diffeomorphism $f : W \to W'$ between open subsets of the object spaces of two ep-groupoids, with $\Theta' \circ f = \Theta$ on W, a local branching structure (U, M_i, σ_i) of Θ at x gives one of Θ' at $f(x)$: the open set $f(U \cap W)$ Chapter11/BranchedEquivalence · EpGroupoid.LocalBranchingStructure.mapU Chapter11/BranchedEquivalence · EpGroupoid.LocalBranchingStructure.mem_image_iff_of_mem_mapU, the sheets $f(M_i \cap W)$, first restricted to W, with the same weights Chapter11/BranchedEquivalence · EpGroupoid.LocalBranchingStructure.mapDiffeo. The sheets keep their dimension Chapter11/BranchedEquivalence · EpGroupoid.LocalBranchingStructure.isOfDim_mapDiffeo, because the dimension of a submanifold at a point is invariant under sc-diffeomorphisms Chapter11/BranchedEquivalence · MPolyfold.HasDimAt.of_image Chapter11/BranchedEquivalence · MPolyfold.hasDimAt_image_iff_of_isScDiffeoOn Chapter11/BranchedEquivalence · MPolyfold.IsSubmanifoldOfDim.image_isScDiffeoOn.

The step for an equivalence. *Step 1, supports.* $|\mathrm{supp}(F^*\Theta')| = |F|^{-1}(|\mathrm{supp}(\Theta')|)$ Chapter11/BranchedEquivalence · EpFunctor.orbitSupp_pullbackTheta and, for full F, $|\mathrm{supp}(F_*\Theta)| = |F|(|\mathrm{supp}(\Theta)|)$ Chapter11/BranchedEquivalence · EpFunctor.orbitSupp_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.exists_mem_supp_of_mem_supp_pushforwardTheta; since $|F|$ is a homeomorphism, the paracompactness of 2021 Definition 9.1.2 (1) transfers, a point the proof does not mention. *Step 2, local branching structures.* For F_*: at y with $\psi : F(x) \to y$, Chapter 10's transport chart $\hat{\psi} \circ F$ Chapter10/

EquivalenceLR · EpFunctor.TransportChart is an sc-diffeomorphism near x with $F_*\Theta \circ \hat{\psi} \circ F = \Theta$, and the structure is moved Chapter11/BranchedEquivalence · EpFunctor.exists_localBranchingStructure_pushforwardTheta; for F^*, F itself near x. Hence **branched ep⁺-subgroupoids go to branched ep⁺-subgroupoids** Chapter11/BranchedEquivalence · EpFunctor.isBranchedEpSubgroupoid_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.isBranchedEpSubgroupoid_pullbackTheta. *Step 3, properties.* Closedness and compactness from Step 1 Chapter11/BranchedEquivalence · EpFunctor.isClosedBranched_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.isClosedBranched_pullbackTheta Chapter11/BranchedEquivalence · EpFunctor.isCompactBranched_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.isCompactBranched_pullbackTheta; orbifold-type from Step 2 Chapter11/BranchedEquivalence · EpFunctor.isOrbifoldType_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.isOrbifoldType_pullbackTheta; manifold-type by comparing two morphisms $y \to y'$ through the faithfulness of F Chapter11/BranchedEquivalence · EpFunctor.isManifoldType_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.isManifoldType_pullbackTheta. In this step the text writes $\psi \circ \varphi' \circ \psi^{-1} : F(x) \to F(x)$ for $\psi : F(x) \to y$ and $\varphi' : y \to y$; we read $\psi^{-1} \circ \varphi' \circ \psi$ (possible misprint). *Step 4, dimension.* n-dimensionality Chapter11/BranchedEquivalence · EpFunctor.isNDimensional_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.isNDimensional_pullbackTheta and dimensional decompositions, the push-forward of a sum being the sum of the push-forwards Chapter11/BranchedEquivalence · EpFunctor.exists_pushforwardTheta_eq_apply Chapter11/BranchedEquivalence · EpFunctor.isDimDecomposition_pushforwardTheta Chapter11/BranchedEquivalence · EpFunctor.isDimDecomposition_pullbackTheta.

Theorem 11.3.3 (2017: 11.3) (V11.18). On a representative with both legs equivalences, $f_* = \Phi_* F^*$ and $f^* = F_* \Phi^*$, and each part follows from the step for an equivalence: (1) Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.theorem_11_3_3_one, (2) Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.theorem_11_3_3_two, (3) Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.theorem_11_3_3_three, (4) Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.theorem_11_3_3_four, (5) Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.theorem_11_3_3_five, (6) Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.theorem_11_3_3_six, with n-dimensionality Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.isNDimensional_pushTheta Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.isNDimensional_pullTheta and the support Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.orbitSupp_pushTheta. (6) speaks of "the" dimensional decomposition of Proposition 9.1.11, whose uniqueness does not hold as we read it Chapter9/Propositions · EpGroupoid.not_proposition_9_1_11_rn; it is proved for every dimensional decomposition.

Witnesses (V11.19). On $\mathbb{Z}/2 \ltimes \mathbb{R}$ Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.reflectionEP, $\Theta_0 = 1_{\{0\}}$ Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.reflectionTheta has the local branching structure $U = \mathbb{R}$, $M = \{0\}$ at the point with isotropy $\mathbb{Z}/2$ Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.localBranchingStructure_reflectionTheta Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.isBranchedEpSubgroupoid_reflectionTheta. Along the refinement of the covering $\{x > -1\}$, $\{x < 1\}$ Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.reflectionCoverEP, a functor not injective on objects, $F^*\Theta_0$ is a branched ep⁺-subgroupoid Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.isBranchedEpSubgroupoid_pullbackTheta_reflectionCover, equal to 1 at the two objects over 0 Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.pullbackTheta_reflectionCover_two_points, and $F_* F^* \Theta_0 = \Theta_0$ Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.pushforwardTheta_pullbackTheta_reflectionCover. $F^*\Theta_0$ Chapter11/BranchedEquivalenceLocalization · EpGroupoid.Examples.pushTheta_reflectionCoverDiagram.

XI.8 Lemma 11.3.4 to Theorem 11.3.9 (2017: Lemma 11.6 to Theorem 11.7): sections, orientations, tangents, boundaries

Section functors of $\widehat{Gr}$ (V11.20) Chapter11/BranchedEquivalenceTangentSection · EpGroupoid.IsGrHatSection Chapter11/BranchedEquivalenceTangentSection · EpGroupoid.GrHatSections. $h(x)$ is a finite formal sum of oriented tangent sets at $x \in X_\infty$, natural along morphisms, with no continuity; it is recorded on all objects, 0 off X_∞. Every orientation of Chapter 9 is one Chapter11/BranchedEquivalenceTangentSection · EpGroupoid.IsOrientation.isGrHatSection. *Step 1, (11.8).* $F_*h(y)$ moves $h(x)$ by $T\psi \circ TF(x)$ for a chosen $\psi : F(x) \to y$, the formal sums by the image of carriers and frames Chapter11/BranchedEquivalenceTangent · MPolyfold.OrTangent.map Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pushSection. For an equivalence the value is the same for every ψ Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pushSection_eq: two choices differ by T of a morphism of X, which h absorbs by naturality, as the text says. *Step 2, (11.9).* $F^*h'(x) = TF(x)^{-1}h'(F(x))$, with the inverse of TF on T_xX Chapter11/BranchedEquivalenceTangentSection · MPolyfold.fibreInv Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pullSection. *Step 3, equivalences.* Section functors go to section functors Chapter11/BranchedEquivalenceTangentSection · EpFunctor.isGrHatSection_pushSection Chapter11/BranchedEquivalenceTangentSection · EpFunctor.isGrHatSection_pullSection; $F^*F_* = 1$, $F_*F^* = 1$ Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pullSection_pushSection Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pushSection_pullSection; naturally equivalent equivalences agree Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pushSection_eq_of_natTrans Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pullSection_eq_of_natTrans; composition Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pushSection_comp Chapter11/BranchedEquivalenceTangentSection · EpFunctor.pullSection_comp; base change in the weak fibred product of two equivalences Chapter11/BranchedEquivalenceTangentSection · WeakFibredProduct.pushSection_projRight_pullSection Chapter11/BranchedEquivalenceTangentSection · WeakFibredProduct.pushSection_projLeft_pullSection. *Step 4, Lemma 11.3.4.* On diagrams Chapter11/BranchedEquivalenceTangentSection · EPLocalization.Diagram.pushSection Chapter11/BranchedEquivalenceTangentSection · EPLocalization.Diagram.pullSection, unchanged on equivalent diagrams Chapter11/BranchedEquivalenceTangentSection · EPLocalization.Diagram.pushSection_eq_of_equiv Chapter11/BranchedEquivalenceTangentSection · EPLocalization.Diagram.pullSection_eq_of_equiv; on classes Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pushSection Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pullSection, computed on any representative Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pushSection_homMk Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pullSection_homMk, with the composition laws for generalized isomorphisms through the base change Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pushSection_comp Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pullSection_comp and $(f^{-1})_* = f^*$ Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pushSection_inv. **Lemma 11.3.4** Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.lemma_11_3_4.

Chapter 9 across two M-polyfolds. Chapter 9 moves submanifolds, tangent sets and orientations by sc-diffeomorphisms of one M-polyfold; equivalences need them between open subsets $U \subseteq X$, $U' \subseteq Y$ of two. For such an f: $T_{f(a)}f(A) = Tf(T_aA)$ Chapter11/BranchedEquivalenceTangent · MPolyfold.submanifoldTangent_image_of_isScDiffeoOn, chart vectors in transported charts Chapter11/BranchedEquivalenceTangent · MPolyfold.chartVec_tangentMapOn_of_isScDiffeoOn,

oriented tangent sets Chapter11/BranchedEquivalenceTangent · MPolyfold.IsOrientedAt.map_tangentMapOn, orientations of submanifolds, their frames moved by Tf and their continuity read in the chart $\varphi \circ f^{-1}$ Chapter11/BranchedEquivalenceTangent · MPolyfold.SubmanifoldOrientation.mapDiffeo Chapter11/BranchedEquivalenceTangent · MPolyfold.SubmanifoldOrientation.mapDiffeo_tangent, the reduced tangent condition Chapter11/BranchedEquivalenceTangent · MPolyfold.IsTangentReducedAt.image_of_isScDiffeoOn Chapter11/BranchedEquivalenceTangent · MPolyfold.isTangentReducedAt_image_iff_of_isScDiffeoOn and the boundary of a submanifold Chapter11/BranchedEquivalenceTangent · MPolyfold.mem_submanifoldBoundary_image_iff_of_isScDiffeoOn. For local branching structures moved as in §XI.7: the tangent sums are moved by Tf Chapter11/BranchedEquivalenceTangent · EpGroupoid.LocalBranchingStructure.tangentSum_mapDiffeo; the independence of the tangent sums of Theorem 9.2.1 is local and carried along, by moving structures back by f^{-1}, comparing and moving forward Chapter11/BranchedEquivalenceTangent · EpGroupoid.LocalBranchingStructure.tangentSum_eq_of_isScDiffeoOn; $T\Theta'(Tf\,\alpha) = T\Theta(\alpha)$ Chapter11/BranchedEquivalenceTangent · EpGroupoid.tangentTheta_tangentMapOn and $\partial\Theta'(f(x)) = \partial\Theta(x)$ Chapter11/BranchedEquivalenceTangent · EpGroupoid.boundaryTheta_apply_of_isScDiffeoOn; oriented structures Chapter11/BranchedEquivalenceTangent · EpGroupoid.OrientedBranchingStructure.mapDiffeo Chapter11/BranchedEquivalenceTangent · EpGroupoid.OrientedBranchingStructure.orientedSum_mapDiffeo.

Theorem 11.3.5 (2017: 11.4) (V11.21). Along a transport chart $Q = \hat{\psi} \circ F$, $T\psi_u \circ TF = TQ$ on T_uX Chapter11/BranchedEquivalenceTangentOrientation · EpFunctor.TransportChart.tangentMor_ψ_tangent_obj, so an oriented branching structure at x representing $\hat{T}_\Theta$, moved by Q, represents $F_*\hat{T}_\Theta$ near y Chapter11/BranchedEquivalenceTangentOrientation · EpFunctor.isOrientation_pushSection; for F^*, a structure at $F(x)$ is moved back by a local inverse of F Chapter11/BranchedEquivalenceTangentOrientation · EpFunctor.isOrientation_pullSection. This is the text's proof. For generalized isomorphisms Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.EPLoc.theorem_11_3_5_push Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.EPLoc.theorem_11_3_5_pull. The independence of the tangent sums, which Chapter 9 now proves for every Θ Chapter9/GeneralCorollaries · EpGroupoid.hasIndependentTangentSums, was assumed for Θ and is carried to $F_*\Theta$, $F^*\Theta'$ Chapter11/BranchedEquivalenceTangent · EpFunctor.hasIndependentTangentSums_pushforwardTheta Chapter11/BranchedEquivalenceTangent · EpFunctor.hasIndependentTangentSums_pullbackTheta and to $f_*\Theta$, $f^*\Theta'$ Chapter11/BranchedEquivalenceTangent · EPLocalization.EPLoc.hasIndependentTangentSums_pushTheta Chapter11/BranchedEquivalenceTangent · EPLocalization.EPLoc.hasIndependentTangentSums_pullTheta.

Definition 11.3.6 (2017: 11.5) and (11.10) (V11.22) Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.OrientedBranched Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.OrientedBranched.push Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.OrientedBranched.pull. The structure records Θ, $\hat{T}_\Theta$ and the independence; push-forward and pull-back are oriented branched ep⁺-subgroupoids by Theorems 11.3.3 and 11.3.5; (11.10) Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.OrientedBranched.push_comp Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.OrientedBranched.pull_comp from Lemma 11.3.4 and §XI.6. Of the two inverse laws of (11.10), $f^*f_*\hat{\Theta} = \hat{\Theta}$ is proved for $\hat{T}_\Theta$ zero off X_∞ Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.OrientedBranched.pull_push, and $f_*f^*\hat{\Theta}' = \hat{\Theta}'$ for its two components Chapter11/BranchedEquivalenceLocalization · EPLocalization.EPLoc.pushTheta_pullTheta Chapter11/BranchedEquivalenceTangentSection · EPLocalization.EPLoc.pushSection_pullSection.

Theorem 11.3.7 (2017: 11.5) (V11.23). *Step 1, equivalences.* $T(F_*\Theta)(F(x)) = TF(T\Theta(x))$ Chapter11/BranchedEquivalenceTangent · EpFunctor.tangentValue_pushforwardTheta_obj and, for $\psi : F(x) \to y$, $T(F_*\Theta)(y)$ is $T\Theta(x)$ moved by $T\psi \circ TF(x)$ Chapter11/BranchedEquivalenceTangent · EpFunctor.tangentValue_pushforwardTheta; for the pull-back, with a local inverse of F Chapter11/BranchedEquivalenceTangent · EpFunctor.tangentValue_pullbackTheta. Hence $(TF)_*T\Theta = T(F_*\Theta)$, $(TF)^*T\Theta' = T(F^*\Theta')$, where

TF is an equivalence (Theorem 10.1.7) and $(TF)_*$ the push-forward of Definition 11.3.1 on TX Chapter11/BranchedEquivalenceTangent · EpFunctor.tangentTheta_pushforwardTheta Chapter11/BranchedEquivalenceTangent · EpFunctor.tangentTheta_pullbackTheta. *Step 2, generalized isomorphisms.* Tf is $[Td]$ for the chosen representative Chapter11/BranchedEquivalenceTangent · EPLocalization.EPLoc.tangentFunctor_map_eq (Theorem 11.1.1), and Step 1 applies to both legs Chapter11/BranchedEquivalenceTangent · EPLocalization.EPLoc.theorem_11_3_7_push Chapter11/BranchedEquivalenceTangent · EPLocalization.EPLoc.theorem_11_3_7_pull. The text leaves the proof to the reader.

Theorem 11.3.8 (2017: 11.6) (V11.24). By the local step, $\partial\Theta$ of Definition 9.2.16 is moved pointwise by every chart $\hat{\psi} \circ F$: the text's "$d_M(x)$ is preserved" is the invariance of ∂M above. For equivalences Chapter11/BranchedEquivalenceTangent · EpFunctor.boundaryTheta_pushforwardTheta Chapter11/BranchedEquivalenceTangent · EpFunctor.boundaryTheta_pullbackTheta and generalized isomorphisms, (11.11) Chapter11/BranchedEquivalenceTangent · EPLocalization.EPLoc.theorem_11_3_8_push Chapter11/BranchedEquivalenceTangent · EPLocalization.EPLoc.theorem_11_3_8_pull.

Theorem 11.3.9 (2017: 11.7), for a representative (V11.25). Chapter 9's boundary orientation $\hat{T}_{\partial\Theta}$ is the boundary lift of $\hat{T}_\Theta$ by a boundary operation bd on oriented tangent sets, taken as data. A linear map $T_xX \to T_yY$ transfers bd to bd' if it keeps degree 1 and commutes with them there Chapter11/BranchedEquivalenceTangentOrientation · MPolyfold.IsBoundaryTransfer; the identity does Chapter11/BranchedEquivalenceTangentOrientation · MPolyfold.isBoundaryTransfer_id. A fibre map that transfers them commutes with the degree-1 part and the boundary operation Chapter11/BranchedEquivalenceTangentOrientation · EpGroupoid.mapDomain_boundary_mapDomain_map, so along an equivalence whose maps $T\psi \circ TF(x)$ transfer bd to bd', $F_*\hat{T}_{\partial\Theta} = \hat{T}_{\partial(F_*\Theta)}$ Chapter11/BranchedEquivalenceTangentOrientation · EpFunctor.pushSection_boundaryLift, and dually Chapter11/BranchedEquivalenceTangentOrientation · EpFunctor.pullSection_boundaryLift. With Theorem 11.3.8 for $\partial\Theta$, for a representative $X \xleftarrow{F} A \xrightarrow{\Phi} Y$ and boundary operations on X, A, Y corresponding under $TF(a)^{-1}$ and $T\psi \circ T\Phi(a)$ Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.EPLoc.theorem_11_3_9_push Chapter11/BranchedEquivalenceTangentOrientation · EPLocalization.EPLoc.theorem_11_3_9_pull. That Definition 9.3.8's boundary operation satisfies the hypothesis along equivalences is the next paragraph (G.130, closed).

Theorem 11.3.9 for the intrinsic boundary orientation (V11.25) Chapter11/BoundaryOrientationEquiv · EPLocalization.EPLoc.theorem_11_3_9_push_boundaryOrientation Chapter11/BoundaryOrientationEquiv · EPLocalization.EPLoc.theorem_11_3_9_pull_boundaryOrientation, independent of the representative, with no transfer hypothesis (G.130). *Step 1, sc-diffeomorphisms move the boundary operation.* A presented chart ψ at $f(x)$ gives the presented chart $\psi \circ f$ at x with the same model, so Tf preserves T^R_xX, C_xX and the reduced codimension, and with them Definition 9.3.8's boundary operation: $\partial(Tf_*(L,o)) = Tf_*(\partial(L,o))$ Chapter11/BoundaryOrientationEquiv · MPolyfold.boundaryOp_map_tangentMapOn. "$d_M(x)$ is preserved", in the proof of Theorem 11.3.8, is read for the reduced codimension of T_xM, which for tame M is $d_M(x)$ and is preserved by every sc-diffeomorphism, without tameness. *Step 2, equivalences.* Through the transport chart $\hat{\psi} \circ F$ of Chapter 10, the maps $T\psi \circ TF(x)$ move it for every $\psi : F(x) \to y$ Chapter11/BoundaryOrientationEquiv · EpFunctor.isReducedBoundaryTransfer_tangentMor, and so do the fibre inverses $TF(x)^{-1}$ Chapter11/BoundaryOrientationEquiv · EpFunctor.isReducedBoundaryTransfer_fibreInv. *Step 3, the intrinsic orientation.* $\hat{T}_{\partial\Theta}$ of Definition 9.3.10 is a function of $\hat{T}_\Theta$, computed with the boundary operation pointwise. By Steps 1 and 2 the push-forward along a representative commutes with it Chapter11/BoundaryOrientationEquiv · EPLocalization.Diagram.pushSection_boundaryOrientation Chapter11/BoundaryOrientationEquiv · EPLocalization.Diagram.pullSection_boundaryOrientation. With Theorem 11.3.8 for

$\partial\Theta$, $f_*(\partial\hat{\Theta}) = \partial(f_*\hat{\Theta})$ and the same for f^*. The statement holds for every section of $\widehat{Gr}$, oriented or not. *The boundary-lift form.* For Chapter 9's boundary lift with Definition 9.3.8's operation, the boundary-transfer hypothesis above follows from Steps 1 and 2 `Chapter11/BoundaryOrientationEquiv · MPolyfold.IsReducedBoundaryTransfer.isBoundaryTransfer` `Chapter11/BoundaryOrientationEquiv · EpFunctor.isBoundaryTransfer_tangentMor`, given that f carries tangent sets of tame submanifolds to tangent sets of tame submanifolds `Chapter11/BoundaryOrientationEquiv · MPolyfold.CarriesTameTangents`. This form, which also asks that $f_*\hat{\Theta}$ be tame `Chapter11/BoundaryOrientationEquiv · EPLocalization.EPLoc.theorem_11_3_9_push_boundaryOp`, has those two conditions as hypotheses; they hold along the identity `Chapter11/BoundaryOrientationEquiv · MPolyfold.carriesTameTangents_id` and for Example 9.3.5 `Chapter11/BoundaryOrientationEquiv · EpGroupoid.Examples.theorem_11_3_9_push_boundaryOp_example935`. That sc-diffeomorphisms preserve tame induced structures on submanifolds is not formalized, and the intrinsic form does not need it.

Witnesses (V11.26). The orientation $\hat{T}^1$ of Example 9.3.5 is a section functor on $\mathbb{R}^2$ `Chapter11/BranchedEquivalenceTangentSection · EpGroupoid.Examples.exampleT1_mem_grHatSections`, fixed by the identity `Chapter11/BranchedEquivalenceTangentSection · EpGroupoid.Examples.pushSection_id_exampleT1`; $(\Theta, \hat{T}^1)$ on the trivial ep-groupoid of $\mathbb{R}^2$ `Chapter11/BranchedEquivalenceTangentOrientation · EpGroupoid.Examples.rn2EP` `Chapter11/BranchedEquivalenceTangentOrientation · EpGroupoid.Examples.example935Oriented` is pushed forward along the identity generalized isomorphism `Chapter11/BranchedEquivalenceTangentOrientation · EpGroupoid.Examples.isGeneralizedIso_id_rn2EP` `Chapter11/BranchedEquivalenceTangentOrientation · EpGroupoid.Examples.example935Oriented_push`, and the boundary-transfer hypothesis holds there `Chapter11/BranchedEquivalenceTangentOrientation · EpGroupoid.Examples.isBoundaryTransfer_id_rn2`.

XI.9 §11.4: integration (Theorems 11.4.1, 11.4.2, 11.4.4, 11.4.5, Remark 11.4.3 (2017: Theorems 11.8, 11.9, Remark 11.3))

§11.4 is formalized (G.131). Theorems 11.4.1, 11.4.2 and Remark 11.4.3 hold with no added hypothesis. Theorems 11.4.4 and 11.4.5 were first proved under the class hypothesis of Chapter 9's boundary measures and for $n \geq 2$; they now hold with the text's hypotheses for every $n \geq 1$. The measures are Chapter 9's: the canonical measures of Theorems 9.5.4 and 9.5.5 built from the concrete sheet integrals `Chapter9/BranchedIntegral · EpGroupoid.theorem_9_5_4` `Chapter9/BranchedIntegral · EpGroupoid.theorem_9_5_5`, and the boundary measures of Theorems 9.5.15 and 9.5.16 on sheets covered by countably many graph charts `Chapter9/BoundaryMeasure · EpGroupoid.theorem_9_5_15_msheets` `Chapter9/BoundaryMeasure · EpGroupoid.theorem_9_5_16_msheets`. "Oriented, tame" is read as in §XI.8, and the independence of the tangent sums holds for every Θ.

What the proof uses of the forms. For an equivalence Φ the identity $\mu^{\Phi^*\hat{\Theta}'}_{\Phi^*\omega'} = |\Phi|^*\mu^{\hat{\Theta}'}_{\omega'}$ uses two facts about the pull-back of forms, recorded as a structure `Chapter11/FormEvalPullback · EpGroupoid.FormEval.IsPullback`: $(\Phi^*\omega')(\alpha_1, \dots, \alpha_n) = \omega'(T\Phi\,\alpha_1, \dots, T\Phi\,\alpha_n)$ on the tangent spaces of finite-dimensional submanifolds, and every form on X is a pull-back (§XI.4). Both hold for Ω^n_{ep} `Chapter11/FormEvalPullbackEquivalence · EpFunctor.IsEquivalence.epFormEval_isPullback` and for the direct limit $\Omega^n_{ep,\infty}$ `Chapter11/FormEvalPullbackEquivalence · EP.epFormsInftyEval_isPullback`.

Theorem 11.4.1 for an equivalence (V11.27) `Chapter11/MeasureEquivalence · EpFunctor.theorem_11_4_1_pull_equiv` `Chapter11/MeasureEquivalence · EpFunctor.theorem_11_4_1_push_equiv`. The text takes $U(x)$, $U(F(x))$ on which F is an sc-diffeomorphism, both with the properness property and the natural actions, and moves the local branching structure by F. *Step 1, between two M-polyfolds.* An sc-diffeomorphism

$f : U \to U'$ between open subsets of two M-polyfolds carries graph charts to graph charts in the transported chart Chapter11/GraphChartsDiffeo · MPolyfold.GraphChart.mapDiffeoCross, null sets to null sets Chapter11/GraphChartsDiffeo · MPolyfold.IsHNull.image_of_isScDiffeoOn_cross, and tame induced structures to tame induced structures Chapter11/GraphChartsDiffeo · MPolyfold.HasTameInducedStructure.image_of_isScDiffeoOn. *Step 2, moving structures.* An oriented tame structure is restricted to a smaller natural representation Chapter11/OrientedStructureDiffeo · EpGroupoid.OrientedTameStructure.restrictRep and moved, $(f(M_i \cap W), f_* o_i)$, (σ_i) Chapter11/OrientedStructureDiffeo · EpGroupoid.OrientedTameStructure.move Chapter11/OrientedStructureDiffeo · EpGroupoid.OrientedTameStructure.represents_move. *Step 3, (11.12) = (11.13).* When $\omega_T(Tf \circ \beta) = \omega_S(\beta)$ on the frames of a sheet Chapter11/OrientedStructureDiffeo · EpGroupoid.FormEval.EvCompatOn, $\int_{f(A)} \omega_T|(f(N), f_* o) = \int_A \omega_S|(N, o)$ Chapter11/OrientedStructureDiffeo · EpGroupoid.FormEval.integ_image_cross, and so the weighted sums of a structure and of its moved structure agree Chapter11/OrientedStructureDiffeo · EpGroupoid.OrientedTameStructure.sheetSum_move; the same holds for sheets covered by several graph charts Chapter11/MultiChartSheetsEquivalence · EpGroupoid.FormEval.image_mem_msheets_cross Chapter11/MultiChartSheetsEquivalence · EpGroupoid.FormEval.msInteg_image_cross. *Step 4, the transport chart.* For $Q = \widehat{\psi} \circ \Phi$ (Chapter 10), Q preserves X_∞ and $\Phi^*\Theta'$ Chapter11/OrientedStructurePairs · EpFunctor.TransportChart.pullbackTheta_Q, moves the orientations Chapter11/OrientedStructurePairs · EpFunctor.TransportChart.pullSection_Q and moves ω' to $\Phi^*\omega'$ Chapter11/OrientedStructurePairs · EpFunctor.TransportChart.evCompatOn_Q. For small $U(x)$ there are natural representations on $U(x)$ and on $Q(U(x))$ Chapter11/OrientedStructurePairs · EpFunctor.TransportChart.exists_rep_push. A structure at y is restricted to $Q(U(x))$ and moved to x by Q^{-1} Chapter11/OrientedStructurePairs · EpGroupoid.OrientedTameStructure.pullStructure Chapter11/OrientedStructurePairs · EpGroupoid.OrientedTameStructure.represents_pullStructure, and one at x is moved to y by Q Chapter11/OrientedStructurePairs · EpGroupoid.OrientedTameStructure.exists_push_structure; this is the text's "$F^*\hat{\Theta}'$, $F_*\hat{\Theta}$ are oriented and tame" Chapter11/MeasureEquivalence · EpFunctor.hcov_pull Chapter11/MeasureEquivalence · EpFunctor.hcov_push. *Step 5, the isotropy factor.* $\sharp G_x = \sharp G_y$ by the isomorphism $g \mapsto \psi \circ \Phi(g) \circ \psi^{-1}$ Chapter10/EquivalenceLR · EpFunctor.TransportChart.bijective_conj. *Step 6, $\mathcal{L}$.* $|\Phi|$ and its inverse map sets of measure zero (Definition 9.5.1) to sets of measure zero Chapter11/MeasureEquivalence · EpFunctor.isMeasureZeroSupp_image Chapter11/MeasureEquivalence · EpFunctor.isMeasureZeroSupp_preimage, so $|\Phi| : |\operatorname{supp} \Phi^*\Theta'| \to |\operatorname{supp} \Theta'|$ is an isomorphism of the σ-algebras $\mathcal{L}$ Chapter11/MeasureEquivalence · EpFunctor.measurable_suppMap Chapter11/MeasureEquivalence · EpFunctor.measurable_suppInv. The text uses this without comment. *Step 7, gluing.* By Steps 3–5 the local formulas of Theorem 9.5.4 for $\mu^{\Phi^*\hat{\Theta}'}_{\Phi^*\omega'}$ and for $\mu^{\hat{\Theta}'}_{\omega'} \circ |\Phi|$ agree on the sets $|U(x)|$, and the measure with these local formulas is unique Chapter9/MeasureGlue · existsUnique_linearMap_signedMeasure_of_openCover Chapter11/MeasureEquivalence · EpFunctor.measure_pull_core. The push-forward identity is the same with $\Phi_*\omega$ any ω' with $\Phi^*\omega' = \omega$. The integrals follow with $K = |\operatorname{supp}|$ Chapter11/MeasureEquivalence · EpFunctor.integral_pull_equiv Chapter11/MeasureEquivalence · EpFunctor.integral_push_equiv.

Theorem 11.4.1 (2017: 11.8) and Remark 11.4.3 (2017: 11.3) (V11.27, V11.28) Chapter11/MeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_1_pull Chapter11/MeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_1_push. As in the text: for equivalences $F : A \to X$, $G : A \to Y$ and $\Theta_A = F^*\Theta_X = G^*\Theta_Y$, the equivalence case along F and along G gives $\mu^{\hat{\Theta}_X}_{\omega_X}(K) = \mu^{\hat{\Theta}_Y}_{\omega_Y}(|G|(|F|^{-1}(K)))$ when $F^*\omega_X = G^*\omega_Y$ Chapter11/MeasureGeneralizedIso · EpFunctor.measure_span_core. With the forms of Definition 11.2.7 on the chosen representative this is the theorem for diagrams Chapter11/MeasureGeneralizedIso · EPLocalization.Diagram.theorem_11_4_1_pull Chapter11/MeasureGeneralizedIso · EPLocalization.Diagram.theorem_11_4_1_push and for generalized isomorphisms. Remark 11.4.3, in the form Chapter 11 uses it: two ep-groupoid models related by a generalized isomorphism give the same branched integrals Chapter11/MeasureGeneralizedIso · EPLocalization.

EPLoc.integral_pull Chapter11/MeasureGeneralizedIso · EPLocalization.EPLoc.integral_push Chapter11/MeasureGeneralizedIso · EPLocalization.EPLoc.remark_11_4_3. The relation on pairs (X, β) in Remark 11.4.3 is Chapter 10's.

Theorem 11.4.2 (new in 2021) (V11.27) Chapter11/EffectiveMeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_2_pull Chapter11/EffectiveMeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_2_push. "The proof is similar to the previous theorem"; the one new step is $\sharp G_x^{eff} = \sharp G_y^{eff}$ along a transport chart Chapter11/EffectiveMeasureEquivalence · EpFunctor.TransportChart.card_effIsotropy_eq. The isomorphism of Step 5 carries $\ker \Phi_R = T_x$ onto $\ker \Phi_{R'} = T_y$ for natural representations on $U(x)$ and on $Q(U(x))$, by the equivariance of Q. Under the local unique continuation property every natural representation has the property used, and the property passes along equivalences (Proposition 10.1.16), so the covering hypotheses of Theorem 9.5.5 pass to $\Phi^*\widehat{\Theta}'$, $\Phi_*\widehat{\Theta}$ Chapter11/EffectiveMeasureEquivalence · EpFunctor.hcovL_pull Chapter11/EffectiveMeasureEquivalence · EpFunctor.hcovL_push. Then the proof of Theorem 11.4.1 Chapter11/EffectiveMeasureEquivalence · EpFunctor.measure_pull_core_eff Chapter11/EffectiveMeasureEquivalence · EpFunctor.theorem_11_4_2_pull_equiv Chapter11/EffectiveMeasureEquivalence · EpFunctor.theorem_11_4_2_push_equiv, and the diagram step, the middle A having the property by Proposition 10.1.16 Chapter11/EffectiveMeasureGeneralizedIso · EpFunctor.measure_span_core_eff. The hypotheses are the text's.

Theorems 11.4.4 and 11.4.5 (2017: 11.9) (V11.29) Chapter11/BoundaryMeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_4_pull Chapter11/BoundaryMeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_4_push Chapter11/BoundaryMeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_5_pull Chapter11/BoundaryMeasureGeneralizedIso · EPLocalization.EPLoc.theorem_11_4_5_push. The text says that there are versions of Theorems 11.4.1 and 11.4.2 for the boundary case, relying on Theorems 9.5.15 and 9.5.16. *Step 1, boundary sheets move.* $\partial_1 f(M) = f(\partial_1 M)$, the reduced codimension being preserved Chapter11/BoundarySheetsDiffeo · EpGroupoid.boundaryStratum_image_cross. The boundary orientation is moved by Tf Chapter11/BoundarySheetsDiffeo · EpGroupoid.OrientedTameStructure.boundarySheet_move Chapter11/BoundarySheetsDiffeo · EpGroupoid.OrientedTameStructure.boundaryOrient_move_tangent, by the boundary operation of §XI.8, Step 1, and the boundary sums of Theorem 9.5.15 agree for a structure and its moved structure Chapter11/BoundarySheetsDiffeo · EpGroupoid.OrientedTameStructure.boundarySheetSum_move, with the change of variables for the multi-chart integrals. *Step 2, the measures.* The boundary measures, the unique maps of Theorems 9.5.15 and 9.5.16 Chapter11/BoundaryMeasureEquivalence · EpGroupoid.boundaryMeasure Chapter11/BoundaryMeasureEquivalence · EpGroupoid.boundaryMeasureEff. $|\Phi|$ is measurable both ways on the boundary supports Chapter11/BoundaryMeasureEquivalence · EpFunctor.measurable_bsuppMap Chapter11/BoundaryMeasureEquivalence · EpFunctor.measurable_bsuppInv, and the gluing argument of Step 7 applies to any pair of measures with the local formulas of Theorem 9.5.15 Chapter11/BoundaryMeasureEquivalence · EpFunctor.measure_pull_core_bd Chapter11/BoundaryMeasureEquivalence · EpFunctor.theorem_11_4_4_pull_equiv Chapter11/BoundaryMeasureEquivalence · EpFunctor.theorem_11_4_5_push_equiv. *Step 3, diagrams* Chapter11/BoundaryMeasureGeneralizedIso · EpFunctor.measure_span_core_bd. *The added hypothesis.* The boundary measures of Chapter 9 carry the class hypothesis `hcov`: the nonempty boundary sheets of the structures lie in the class of integrated sheets, with finite $\int |\omega|$ over $\partial_1 M_i$. It is derived from the text's hypotheses (§IX.36). It passes along equivalences and diagrams Chapter11/BoundaryMeasureEquivalence · EpFunctor.hcovB_pull Chapter11/BoundaryMeasureEquivalence · EpFunctor.hcovB_push Chapter11/BoundaryMeasureGeneralizedIso · EPLocalization.Diagram.hcovB_pullTheta Chapter11/BoundaryMeasureGeneralizedIso · EPLocalization.Diagram.hcovB_pushTheta. Its satisfiability witnesses: compact boundary sheets Chapter9/BoundaryMeasure · EpGroupoid.hcov_msheets_of_isCompact and, with nonempty boundary, the closed upper hemisphere in $[0, \infty) \times \mathbb{R}^2$ Chapter9/HemisphereWitness · E8W.e8w_hcov Chapter9/

StokesBoundaryMeasure · EP.hcovB_of_hcovS. These first forms have $n = m + 1$ with $m > 0$.

Theorems 11.4.4 and 11.4.5 with the text's hypotheses (V11.29, restated; gap G.131, closed). $n \geq 2$ Chapter11/BoundaryMeasureTextHypotheses · EPLocalization.EPLoc.theorem_11_4_4_pull_loc Chapter11/BoundaryMeasureTextHypotheses · EPLocalization.EPLoc.theorem_11_4_4_push_loc Chapter11/BoundaryMeasureTextHypotheses · EPLocalization.EPLoc.theorem_11_4_5_pull_loc Chapter11/BoundaryMeasureTextHypotheses · EPLocalization.EPLoc.theorem_11_4_5_push_loc. For a generalized isomorphism f and $\hat{\Theta}'$ compact, branched, oriented and tame (`hloc`), $|f|(K)$ is measurable and $\mu^{\partial f^*\hat{\Theta}'}_{f^*\omega'}(K) = \mu^{\partial\hat{\Theta}'}_{\omega'}(|f|(K))$; for $\hat{\Theta}$ with the same hypotheses $\mu^{\partial\hat{\Theta}}_{\omega}(K) = \mu^{\partial f_*\hat{\Theta}}_{f_*\omega}(|f|(K))$; the same for the effective measures when both ep-groupoids have the local unique continuation property. They are the versions above with `hloc` in place of `hcov`, the class condition being derived (§IX.36). The measures are those of Theorems 9.5.15 and 9.5.16 with the text's hypotheses, by definition Chapter11/BoundaryMeasureTextHypotheses · EP.boundaryMeasure_eq Chapter11/BoundaryMeasureTextHypotheses · EP.boundaryMeasureEff_eq; on the transported side the class conditions are the terms `hcovB_pull`, `hcovB_push` above. $n = 1$. The value of a 0-form moves with the point: $(F^*\omega)(p) = \omega(F(p))$ Chapter11/BoundaryMeasureEquivalenceDimOne · EP.zeroFormEval_epFormsInftyPullback, and on a transport chart a boundary point moves to its image with the same frame sign Chapter11/BoundaryMeasureEquivalenceDimOne · EpGroupoid.OrientedTameStructure.boundarySheetSum_move_dim1. The gluing of Step 2 is redone for the point sheets of §IX.38 Chapter11/BoundaryMeasureEquivalenceDimOne · EpFunctor.measure_pull_core_bd_dim1 Chapter11/BoundaryMeasureEquivalenceDimOne · EpFunctor.theorem_11_4_4_pull_equiv_dim1 Chapter11/BoundaryMeasureEquivalenceDimOne · EpFunctor.theorem_11_4_4_push_equiv_dim1 Chapter11/BoundaryMeasureEquivalenceDimOne · EpFunctor.theorem_11_4_5_pull_equiv_dim1 Chapter11/BoundaryMeasureEquivalenceDimOne · EpFunctor.theorem_11_4_5_push_equiv_dim1, then for spans Chapter11/BoundaryMeasureGeneralizedIsoDimOne · EpFunctor.measure_span_core_bd_dim1 and for generalized isomorphisms Chapter11/BoundaryMeasureGeneralizedIsoDimOne · EPLocalization.EPLoc.theorem_11_4_4_pull_dim1 Chapter11/BoundaryMeasureGeneralizedIsoDimOne · EPLocalization.EPLoc.theorem_11_4_4_push_dim1 Chapter11/BoundaryMeasureGeneralizedIsoDimOne · EPLocalization.EPLoc.theorem_11_4_5_pull_dim1 Chapter11/BoundaryMeasureGeneralizedIsoDimOne · EPLocalization.EPLoc.theorem_11_4_5_push_dim1, with the measures of the $n = 1$ Theorems 9.5.15 and 9.5.16.

XI.10 Proposition 11.5.1 (2017: 11.6): auxiliary norms

The orbit map on $|W[1]|$. $W_{0,1}$ with the morphisms of W has orbit space $|W[1]|$; the map $|W[1]| \to |W|$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.oneToOrbit is injective Chapter11/StrongBundleUpToEquivalence · SBLocalization.oneToOrbit_injective. A strong bundle functor induces a continuous map on $|W[1]|$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.oneMap Chapter11/StrongBundleUpToEquivalence · SBLocalization.continuous_oneMap Chapter11/StrongBundleUpToEquivalence · SBLocalization.oneToOrbit_oneMap, and a diagram with both legs strong bundle equivalences the map $|D| = |\Psi| \circ |\Phi|^{-1}$ on $|W[1]|$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.oneOrbitMap Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.continuous_oneOrbitMap Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.oneOrbitMap_oneMap Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.oneToOrbit_oneOrbitMap, determined by $|D|$ on $|W|$ because $|W[1]| \to |W|$ is injective Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.oneOrbitMap_eq_of_orbitMap_eq.

Proposition 11.5.1 (V11.30) Chapter11/StrongBundleUpToEquivalence · SBLocalization.GenSBMap.

proposition_11_5_1. A function on $W_{0,1}$ is invariant if it is constant along morphisms Chapter11/StrongBundleUpToEquivalence · SBLocalization.IsOneInvariant Chapter11/StrongBundleUpToEquivalence · SBLocalization.isOneInvariant_iff Chapter11/StrongBundleUpToEquivalence · SBLocalization.isOneInvariant_const; auxiliary norms are, by condition (3) Chapter11/StrongBundleUpToEquivalence · EpStrongBundle.IsAuxNorm.isOneInvariant. *Step 1, the definition.* $[D]^*N'(e) = N'(e')$ for a representative e' of $|D|(|e|)$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullNorm Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pushNorm; for invariant N' it does not depend on the representative Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullNorm_eq and equals the text's $N'(\Psi(e''))$ for every e'' with $\Phi(e'') \cong e$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullNorm_eq_Ψ Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullNorm_eq_lift. *Step 2, the properties.* It is invariant Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.isOneInvariant_pullNorm and continuous, as the map induced by N' on $|W'[1]|$ composed with $|D|$ and the quotient map Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.continuous_pullNorm; the two are inverse Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pushNorm_pullNorm Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullNorm_pushNorm and depend only on the orbit map Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullNorm_eq_of_orbitMap_eq Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pushNorm_eq_of_orbitMap_eq. *Step 3, classes.* Hence well defined on generalized strong bundle isomorphisms Chapter11/StrongBundleUpToEquivalence · SBLocalization.GenSBMap.pullNorm Chapter11/StrongBundleUpToEquivalence · SBLocalization.GenSBMap.pushNorm. *Step 4, conditions (1) and (2) of Definition 8.3.5* (G.132) Chapter11/AuxiliaryNormTransport2021 · SBLocalization.GenSBMap.proposition_11_5_1_book, the statement as printed with no added hypothesis; the text calls it a consequence of the definitions. (1) On a fibre of $W_{0,1}$, $[D]^*N'$ is N' composed with linear isomorphisms: the action $\mu(\sigma,\cdot)$ between fibres at level 1 Chapter11/AuxiliaryNormTransport2021 · SBLocalization.oneFiberMor and a strong bundle equivalence on fibres Chapter11/AuxiliaryNormTransport2021 · SBLocalization.oneFiberObj. A complete norm stays complete along a linear isomorphism Chapter11/AuxiliaryNormTransport2021 · StrongBundle.IsCompleteFiberNorm.of_linearEquiv, so the norm is complete Chapter11/AuxiliaryNormTransport2021 · SBLocalization.SDiagram.isCompleteFiberNorm_pullNorm. (2) For h_k with $P(h_k) \to x$ and $[D]^*N'(h_k) \to 0$: fix $\sigma : \phi(x'') \to x$, a local inverse τ of the target map at σ and a local inverse of ϕ at x'', and lift h_k to e''_k over $g(s(\tau(P(h_k))))$. Condition (2) for N' gives $\Psi(e''_k) \to 0$. A strong bundle equivalence is a local homeomorphism of $W[1]$ near 0 (Definition 10.4.1 (2)) Chapter11/AuxiliaryNormTransport2021 · SBLocalization.tendsto_zeroOne_of_tendsto_obj, so $e''_k \to 0$, and $h_k = \mu(\tau(\cdot), \Phi(e''_k)) \to 0$ Chapter11/AuxiliaryNormTransport2021 · SBLocalization.SDiagram.tendsto_zeroOne_pullNorm. Hence $[D]^*N'$ is an auxiliary norm Chapter11/AuxiliaryNormTransport2021 · SBLocalization.SDiagram.isAuxNorm_pullNorm, and $[D]_*N$ is one as the pull-back along the reversed diagram Chapter11/AuxiliaryNormTransport2021 · SBLocalization.SDiagram.isAuxNorm_pushNorm. The sentence of p. 547 deriving $[D] = [D']$ from the local regularity property is Theorem 10.5.7, which does not hold as we read it (Chapter 10); Step 2 needs only $|[D]| = |[D']|$.

XI.11 Lemma 11.5.2 and Proposition 11.5.3 (2017: 11.7 and 11.7): multisection functors

Functors on W (V11.31) Chapter11/StrongBundleUpToEquivalence · SBLocalization.IsWFunctor Chapter11/StrongBundleUpToEquivalence · SBLocalization.isWFunctor_const. A map Λ on the total space constant along $\mu(\varphi, w)$ takes equal values over isomorphic objects Chapter11/StrongBundleUpToEquivalence · SBLocalization.IsWFunctor.eq_of_π_eq. $\Psi^*\Lambda' = \Lambda' \circ \Psi$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.pullMult

Chapter11/StrongBundleUpToEquivalence · SBLocalization.IsWFunctor.pullMult. **Lemma 11.5.2 (2017: 11.7)** Chapter11/StrongBundleUpToEquivalence · SBLocalization.lemma_11_5_2: for a strong bundle equivalence, $\Phi_*\Lambda(w')$ is Λ at a chosen w with $\Phi(w) \cong w'$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.pushMult Chapter11/StrongBundleUpToEquivalence · SBLocalization.π_obj_choose, equal for every such w Chapter11/StrongBundleUpToEquivalence · SBLocalization.pushMult_eq, a functor; with the inverse laws Chapter11/StrongBundleUpToEquivalence · SBLocalization.pullMult_pushMult Chapter11/StrongBundleUpToEquivalence · SBLocalization.pushMult_pullMult.

Proposition 11.5.3 (2017: 11.7) (V11.32) Chapter11/StrongBundleUpToEquivalence · SBLocalization.GenSBMap.proposition_11_5_3. On diagrams $[D]_* = \Psi_*\Phi^*$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pushMult and $[D]^* = \Phi_*\Psi^*$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullMult; $[D]_*\Lambda(w') = \Lambda(w)$ whenever $|D|(|w|) = |w'|$ Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pushMult_eq Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullMult_eq, so everything depends on $|D|$ only: functors go to functors Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.isWFunctor_pushMult Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.isWFunctor_pullMult, the two are inverse Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullMult_pushMult Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pushMult_pullMult and agree for equal orbit maps Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pushMult_eq_of_orbitMap_eq Chapter11/StrongBundleUpToEquivalence · SBLocalization.SDiagram.pullMult_eq_of_orbitMap_eq; on classes Chapter11/StrongBundleUpToEquivalence · SBLocalization.GenSBMap.pushMult Chapter11/StrongBundleUpToEquivalence · SBLocalization.GenSBMap.pullMult. The text's "generalized strong bundle maps" in the last clause is read as generalized strong bundle isomorphisms, for which $[D]_*$ is defined.

sc⁺-multisections: Lemma 11.5.2 and Proposition 11.5.3 as stated (V11.31, V11.32) Chapter11/MultisectionLocalStructure2021 · SBLocalization.lemma_11_5_2_book Chapter11/MultisectionLocalStructure2021 · SBLocalization.GenSBMap.proposition_11_5_3_book, with no added hypothesis (G.133). *Definition 13.2.1.* An sc⁺-multisection is a functor $\Lambda : W \to \mathbb{Q}^+$ Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsScPlusMultisection with a local section structure around every x_0: on the domain $U(x_0)$ of a natural representation, sc⁺-sections $s_1, \dots, s_k$ with positive rational weights summing to 1 and $\Lambda(w) = \sum_{i:w=s_i(P(w))} \sigma_i$ Chapter11/MultisectionLocalStructure2021 · SBLocalization.HasLocalSectionStructure. Such a representation on any open neighbourhood Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsLocalRepOn gives a local section structure, by shrinking to a natural representation (Theorem 7.1.13). The weights and values are in $\mathbb{Q}_{\geq 0}$, which contains the value 0 off the sections. *Step 1, pull-back.* $\Lambda' \circ \Phi$ has the local sections $\Phi_U^{-1} \circ s_i \circ \phi$ Chapter11/MultisectionLocalStructure2021 · SBLocalization.isScPlusMultisection_pullMult. *Step 2, push-forward, the text's construction.* Around x', with $\sigma' : \phi(x) \to x'$, $s_i'(y') = \mu'(\sigma', \Phi(s_i(x)))$ with σ' extended by the local inverse τ of t' at σ' and the local inverse g of ϕ. The sections are defined on $O' = \{y' : s(\tau(y')) \in \phi(U),\ g(s(\tau(y'))) \in O\}$ and take arbitrary values off O' Chapter11/MultisectionLocalStructure2021 · SBLocalization.exists_isLocalRepOn_pushMult. *Step 3, diagrams and classes.* $\Psi_*\Phi^*$ and $\Phi_*\Psi^*$ Chapter11/MultisectionLocalStructure2021 · SBLocalization.SDiagram.isScPlusMultisection_pushMult Chapter11/MultisectionLocalStructure2021 · SBLocalization.SDiagram.isScPlusMultisection_pullMult, with the rest of Proposition 11.5.3 from the previous paragraph. *Witness*, the multisection of the zero section Chapter11/MultisectionLocalStructure2021 · SBLocalization.isScPlusMultisection_zeroMultisection.

XI.12 Lemmas 11.6.1–11.6.3 (2017: Lemmas 11.8, 11.9): the fibres of a proper covering

Lemma 11.6.1 (V11.33) `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.lemma_11_6_1`. For a proper covering functor $F : Y \to X$, $\alpha : \psi \mapsto (F(\psi), s(\psi))$ is an sc-diffeomorphism onto the fibred product (Definition 8.5.1), so every (φ, y) with $F(y) = s(\varphi)$ has a unique lift `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.lift` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.mor_lift` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.src_lift` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.eq_lift` over $t(\varphi)$ `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.obj_tgt_lift`; lifts with prescribed target are unique as well `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.existsUnique_lift_tgt`. Surjectivity on morphisms comes from surjectivity on objects, and the local sc-diffeomorphism property from α and the source map.

The action and Lemma 11.6.2 (2017: 11.8) (V11.34) `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.lemma_11_6_2`. The fibre Y_x `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.Fiber` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.Fiber.val` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.Fiber.mk` carries $g * y = t(\alpha^{-1}(g, y))$ `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.fiberSMul` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.fiberSMul_val_of`, an action ((11.15)) `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.instMulActionFiber` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.smul_val_of`: $\alpha^{-1}(g_2 g_1, y)$ and $\alpha^{-1}(g_2, g_1 * y) \circ \alpha^{-1}(g_1, y)$ have the same image under α. In the text's display of $\alpha(\psi_2 \circ \psi_1)$ the second factor is printed $(F(\psi_2), s(\psi_1))$; we read $(F(\psi_1), s(\psi_1))$ (possible misprint). The full subcategory $Y(x)$ `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.FiberFull` and the translation groupoid `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.Translation` are related by the functor that is the identity on objects and α on morphisms `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.toTranslation`, bijective on objects, full and faithful `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.bijective_toTranslation_obj` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.full_toTranslation` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.faithful_toTranslation`: the "natural identification".

Lemma 11.6.3 (2017: 11.9) (V11.35) `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.lemma_11_6_3`. $B_\varphi(y) = t(\mathrm{lift}(\varphi, y))$ `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.transportFiber` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.transportFiber_val_of`, with inverse $B_{\varphi^{-1}}$ `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.transportFiber_inv_transportFiber` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.bijective_transportFiber`, equivariant along conjugation `Chapter7/Basic · EpGroupoid.conjIsotropy` `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.transportFiber_smul`, by uniqueness of lifts. $\tilde{\varphi}$ `Chapter11/CoveringEquivalence · EpFunctor.IsProperCovering.translationMap` is bijective on objects, full and faithful.

XI.13 Definitions 11.6.4 and 11.6.5 (2017: 11.6 and 11.7)

Definition 11.6.4 (2017: 11.6) (V11.36) `Chapter11/CoveringEquivalence · ProperCoveringHom` `Chapter11/CoveringEquivalence · ProperCoveringHom.ext`. Ψ maps fibres into fibres `Chapter11/CoveringEquivalence · ProperCoveringHom.mapsTo_fiber`; identities and composites `Chapter11/CoveringEquivalence · ProperCoveringHom.id` `Chapter11/CoveringEquivalence · ProperCoveringHom.comp`. (2): the fibre condition `Chapter11/CoveringEquivalence · ProperCoveringHom.IsFiberBijective` and equivalences `Chapter11/CoveringEquivalence · ProperCoveringHom.IsEquivalence` `Chapter11/CoveringEquivalence · ProperCoveringHom.`

IsEquivalence.id Chapter11/CoveringEquivalence · ProperCoveringHom.IsEquivalence.comp. *The fibre condition is redundant* Chapter11/CoveringEquivalence · ProperCoveringHom.isFiberBijective_of_isEquivalence Chapter11/CoveringEquivalence · ProperCoveringHom.isEquivalence_iff. *Injectivity.* If $\Psi(y_1) = \Psi(y_2)$ with $F(y_1) = F(y_2) = x$, fullness of Ψ gives $\eta : y_1 \to y_2$ with $\Psi(\eta) = 1$; then $\Phi(F(\eta)) = F'(\Psi(\eta)) = 1 = \Phi(1_x)$ and faithfulness of Φ give $F(\eta) = 1_x$, so η and 1_{y_1} lift the same $(1_x, y_1)$ and $y_2 = y_1$. *Surjectivity.* For $y' \in Y'_{\Phi(x)}$, essential surjectivity gives y and $\eta' : \Psi(y) \to y'$; $F'(\eta') : \Phi(F(y)) \to \Phi(x)$ is $\Phi(\varphi)$ for some $\varphi : F(y) \to x$ by fullness; then $\Psi(\mathrm{lift}(\varphi, y))$ and η' lift the same morphism with the same source, so $\Psi(B_\varphi(y)) = y'$. *Witness.* The functor from the pair groupoid of $\mathbb{Z}$ to the point, between the identity coverings Chapter11/CoveringEquivalence · CoveringEquivalence.Examples.pairToPointCovering, is an equivalence Chapter11/CoveringEquivalence · CoveringEquivalence.Examples.isEquivalence_pairToPointCovering.

Definition 11.6.5 (2017: 11.7) (V11.37) Chapter11/CoveringEquivalence · ProperCoveringHom.NatTrans Chapter11/CoveringEquivalence · ProperCoveringHom.NaturallyEquivalent. (11.20) objectwise; the square after the definition Chapter11/CoveringEquivalence · ProperCoveringHom.NatTrans.naturality_F. Identity, inverse and composite Chapter11/CoveringEquivalence · ProperCoveringHom.NatTrans.refl Chapter11/CoveringEquivalence · ProperCoveringHom.NatTrans.symm Chapter11/CoveringEquivalence · ProperCoveringHom.NatTrans.trans, whiskerings Chapter11/CoveringEquivalence · ProperCoveringHom.NatTrans.whiskerLeft Chapter11/CoveringEquivalence · ProperCoveringHom.NatTrans.whiskerRight; natural equivalence is an equivalence relation Chapter11/CoveringEquivalence · ProperCoveringHom.naturallyEquivalent_equivalence compatible with composition Chapter11/CoveringEquivalence · ProperCoveringHom.NaturallyEquivalent.comp_left Chapter11/CoveringEquivalence · ProperCoveringHom.NaturallyEquivalent.comp_right. Witness Chapter11/CoveringEquivalence · CoveringEquivalence.Examples.naturallyEquivalent_pairToPointCovering.

XI.14 Theorem 11.6.6 (2017: 11.10)

The functor H (V11.38) Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.hObj Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.hMor Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.hFunctor. On morphisms (11.19), with sources and targets checked through the commutation equations Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.mor_conj Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.hMor_src Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.hMor_tgt. Assume Ψ and Φ are local sc-diffeomorphisms on objects and Ψ maps each Y_x onto $Y'_{\Phi(x)}$. *Step (A), objects.* Surjectivity: for (x, φ', x'') lift x'' to y'', then $\varphi' : \Phi(x) \to \xi(x'')$ along F' to ψ' with target $\zeta(y'')$; the source of ψ' lies over $\Phi(x)$, so it is $\Psi(y)$ for some $y \in Y_x$ by the hypothesis on fibres Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.surjective_hObj. The local sc-diffeomorphism property: the projections $P \to Y''$ and $Q \to X''$ are local sc-diffeomorphisms on objects because Ψ and Φ are, F'' is one, and $\pi_{X''} \circ H = F'' \circ \pi_{Y''}$, so H is one by two out of three Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.isLocalScDiffeo_hObj. The text's heading of (A) has P and Q in the reverse order (possible misprint). *Step (B), α.* The map $\psi \mapsto (H(\psi), s(\psi))$ for H is an sc-diffeomorphism onto the fibred product, its inverse built from those of F and F'' Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.isScDiffeo_fibredMap_hFunctor. *Step (C), finite fibres and properness.* A fibre of H sits in the product of fibres of F and F'' Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.finite_fiber_hObj; a proper covering is proper on objects Chapter11/CoveringEquivalenceTheorem · EpFunctor.IsProperCovering.isProperMap, and so is H Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.isProperMap_hObj; a proper local sc-diffeomorphism is evenly covered near a point with finite fibre, by disjoint sheets around the points of the fibre and the closedness

of proper maps Chapter11/CoveringEquivalenceTheorem · MPolyfold.IsLocalScDiffeo.evenlyCovered_of_isProperMap, the sheets cut down to the neighbourhood found Chapter11/CoveringEquivalenceTheorem · MPolyfold.IsScDiffeoOn.restrictTarget. The properness of H is an ultrafilter argument from the properness of F and F'' on objects and the continuity of the inverse of the map α of F'; it replaces the text's argument with sequences. **(1)** Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.isProperCovering_hFunctor_of.

Theorem 11.6.6 (V11.39) Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.theorem_11_6_6. An equivalence (Ψ, Φ) satisfies the hypotheses of (1), the fibre condition by §XI.13. *Step (D), (2).* $\pi_{Y''}$ and $\pi_{X''}$ are equivalences Chapter10/WeakFibredProductTheorem · WeakFibredProduct.isEquivalence_projRight, so the pair Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.projRightHom is an equivalence by §XI.13. *Step (E), (3).* $\tau_P(y, \psi', y'') = \psi'$ and $\tau_Q(x, \varphi', x'') = \varphi'$ satisfy (11.20) Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.natTransProj. *Step (F), tameness.* $P \to Y''$ and $Q \to X''$ are surjective local sc-diffeomorphisms on objects, and $Y'' \to X''$ is one; tameness pulls back along local sc-diffeomorphisms Chapter7/LocalDiffeo · MPolyfold.IsLocalScDiffeo.isTame. If (ζ, ξ) is an equivalence, the other projection Chapter11/CoveringEquivalenceTheorem · ProperCoveringHom.projLeftHom is one by symmetry. Witness: the equivalence of §XI.13 and the identity of the point Chapter11/CoveringEquivalenceTheorem · CoveringEquivalence.Examples.theorem_11_6_6_pairToPoint, with nonempty fibres Chapter11/CoveringEquivalence · CoveringEquivalence.Examples.nonempty_fiber_id.

XI.15 The category $\mathcal{PC}$, Definition 11.6.7, Proposition 11.6.8 (2017: 11.8, 11.8) and Remark 11.6.9 (2017: 11.4)

$\mathcal{PC}$ (V11.40) Chapter11/CoveringEquivalenceDiagram · PC Chapter11/CoveringEquivalenceDiagram · ProperCoveringHom.comp_assoc Chapter11/CoveringEquivalenceDiagram · PC.equivalences. The weak fibred product as an object, with its projections Chapter11/CoveringEquivalenceDiagram · PC.fibred Chapter11/CoveringEquivalenceDiagram · PC.fibredFst Chapter11/CoveringEquivalenceDiagram · PC.fibredSnd. **Definition 11.6.7 (2017: 11.8)** Chapter11/CoveringEquivalenceDiagram · PC.Diagram Chapter11/CoveringEquivalenceDiagram · PC.Diagram.CommonRefinement Chapter11/CoveringEquivalenceDiagram · PC.Diagram.HasCommonRefinement. The localization and Remark 11.6.9. $\mathcal{PC}(E^{-1})$ and I, whose composition the text leaves to the reader, are §XI.21 (V11.43; G.134). Remark 11.6.9 (V11.42) recalls Definition 8.5.9 Chapter8/Book2021 · EpStrongBundle.

`IsProperStrongBundleCovering2021` and sketches the category of proper strong bundle coverings and its localization, which is §XI.22 (G.135).

XI.16 Witnesses and the hypotheses

Hypotheses taken. *§XI.8.* Chapter 9's independence of the tangent sums of Theorem 9.2.1 was assumed for the branched ep⁺-subgroupoid being moved and proved for its images. Chapter 9 now proves it for every Θ `Chapter9/GeneralCorollaries · EpGroupoid.hasIndependentTangentSums`, so it is no longer a restriction; it holds on $\mathbb{R}^n$ `Chapter9/AppendixSlices · EpGroupoid.hasIndependentTangentSums_rn`. The boundary-transfer hypothesis of Theorem 11.3.9 for a representative holds along the identity, on every M-polyfold and on $\mathbb{R}^2$. Theorem 11.3.9 for the intrinsic boundary orientation needs no hypothesis. The boundary-lift form of Theorem 11.3.9 asks that f carry tame tangent sets and that $f_*\widehat{\Theta}$ be tame; both hold along the identity and for Example 9.3.5. *§XI.9.* The first forms of Theorems 11.4.4 and 11.4.5 carry the class hypothesis `hcov` of Chapter 9; it is derived from the text's hypotheses (§IX.36), and the forms with `hloc` take none beyond the text's. The local regularity property in Propositions 11.2.8, 11.2.9 and the local unique continuation property in Theorems 11.4.2, 11.4.5 are the text's. *Elsewhere.* The branched statements of §11.3 and the category $\mathcal{PC}$ take their ep-groupoids in one universe; the tangent functor on $\mathcal{EP}(E^{-1})$ lives where Chapter 8's T does. In Remark 11.6.9 the class E_{SBPC}, which the text does not define, is read as "both components strong bundle equivalences" (§XI.22). Several statements need less than the text assumes: Lemma 11.3.2 (§XI.5), Proposition 11.1.6 (§XI.3), Theorem 11.6.6 (1) (§XI.14), and Proposition 11.2.8 with the property on one side (§XI.4).

Every definition has a witness. Faces and (weak) face structure: the quadrant with and without the swap (§XI.2). Push-forwards, pull-backs, branched ep⁺-subgroupoids along an equivalence that is not injective on objects and along a generalized isomorphism: $1_{\{0\}}$ on $\mathbb{Z}/2 \ltimes \mathbb{R}$ (§XI.7). Section functors and oriented branched ep⁺-subgroupoids: Example 9.3.5 on $\mathbb{R}^2$ (§XI.8). Auxiliary norms and multisection functors: the constant functions (§§XI.10, XI.11). Functors, equivalences and natural transformations of proper coverings, Theorem 11.6.6, diagrams and common refinements: the pair groupoid of $\mathbb{Z}$ over the point (§§XI.13–XI.15). Two faces meeting in more than one face: $([0,\infty)^3 \oplus W) \setminus K$ (§XI.20). The local regularity property in Propositions 11.2.8 and 11.2.9: the point and $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ (§XI.4). The class hypothesis of Theorems 11.4.4 and 11.4.5: compact boundary sheets and the closed upper hemisphere (§XI.9). sc⁺-multisections: the zero section (§XI.11). $\mathcal{PC}(E^{-1})$: pair $\to$ point (§XI.21). Proper strong bundle coverings and their weak fibred products: $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ (§XI.22).

XI.17 What is not formalized

All eight gaps of Chapter 11 are closed.

- Closed: §11.4 (G.131, §XI.9). Theorems 11.4.1, 11.4.2 and Remark 11.4.3 are proved with no added hypothesis, and Theorems 11.4.4 and 11.4.5 with the text's hypotheses for every $n \geq 1$.
- Closed: §11.1, Proposition 11.1.6 with the second claim of Proposition 11.1.8 (G.128, §§XI.3, XI.19, XI.20; the intersection clause does not hold as we read it, and holds in a union form); §11.2 (G.129, §XI.4); §11.3, Theorem 11.3.9 for the intrinsic boundary orientation (G.130, §XI.8); §11.5, conditions (1) and (2) in Proposition 11.5.1 (G.132, §XI.10) and the local section structures of sc⁺-multisections (G.133, §XI.11); §11.6, $\mathcal{PC}(E^{-1})$ and I (G.134, §XI.21) and the category of Remark 11.6.9 with its localization (G.135, §XI.22).

- Within closed items, the boundary-lift form of Theorem 11.3.9 keeps two hypotheses that the intrinsic form does not need: that sc-diffeomorphisms carry tame induced structures on submanifolds to tame induced structures, and that $f_*\widehat{\Theta}$ is tame. The ordered face structures of Remark 11.1.5 have no formal content.

XI.18 What the formalization taught us

Most of Chapter 11 is Chapter 10's machinery applied to one more kind of object, and the formal work went into the two places where an object is carried along an equivalence by a choice. For functors Θ the choice of x and $F(x) \to y$ does not matter as soon as F is full, which is all that the well-definedness in Lemma 11.3.2 uses; the statements for generalized maps then reduce, through one base change formula in the weak fibred product, to statements for equivalences, and the pull-back is defined for every generalized map. For branched ep$^+$-subgroupoids the text's proof moves a local branching structure by $\widehat{\psi} \circ F$; written out, the sheets must first be cut down to the domain of that local sc-diffeomorphism, and the paracompactness of the support, part of 2021 Definition 9.1.2, must be carried along too. Theorem 11.3.3 (6) refers to the uniqueness of dimensional decompositions, which does not hold as we read it (Chapter 9); the statement for every decomposition is what the proof gives. The rest of §11.3, whose proofs the text leaves to the reader, needed Chapter 9's notions between two M-polyfolds rather than on one, Chapter 9's independence hypothesis carried along, and, for Theorem 11.3.9, a condition on the boundary operations that Chapter 9 takes as data. Faces are a question about $|X|$ alone: once the faces of $|X|$ are Chapter 2's faces for $d_{|X|}$, Remark 11.1.5 and the bijections of Proposition 11.1.6 are statements about homeomorphisms preserving an index, and hold for every generalized isomorphism; only the ep-groupoid structure of a face needs more. In §11.6 the fibre condition of Definition 11.6.4 (2) comes for free for proper coverings, by unique lifting; and the chain of natural equivalences in Proposition 11.6.8 needs one more step than it displays.

What the closing of the gaps shows. Proposition 11.1.6 splits: its first and last claims hold, the faces being tame ep-groupoids because near each of its points X_θ is one face of the object M-polyfold, and the faces of a generalized isomorphism being related by the restricted diagram (11.1); but two faces can meet in several components, so the intersection is a union of faces of each, not one face. In §11.2 the forms behave best when F_* is defined as the inverse of F^*: the bijectivity of F^* is a descent along the projection $X \times_Y Y \to Y$, which is a surjective local sc-diffeomorphism, and the text's formula, composition rules, naturality and independence of the representative all follow by inverting statements about pull-backs. Theorem 11.3.9 needed no condition once the boundary orientation is taken intrinsically: Definition 9.3.8's operation is built from presented charts, which sc-diffeomorphisms transport, and "$d_M(x)$ is preserved" is read for the reduced codimension, which needs no tameness. §11.4 follows the text's proof, structures moved along transport charts and the sums (11.12), (11.13) compared, with two additions: $|f|$ preserves the σ-algebra $\mathcal{L}$, which the text uses silently, and in the effective case $\sharp G^{eff}$ is preserved because the transport isomorphism carries T_x onto T_y. The boundary versions first inherited Chapter 9's class condition near corners; once Chapter 9 derived it, and covered $n = 1$, they hold with the text's hypotheses. In §11.5 conditions (1) and (2) need a local lift of a sequence through local inverses of t and ϕ, and the push-forward of local section structures needs the explicit domain on which the text's sections s_i' are defined. In §11.6 the localizations of $\mathcal{PC}$ and of proper strong bundle coverings follow §10.3 once Theorem 11.6.6 is stated with the equivalence on the left; for strong bundles the weak fibred product is a pull-back, and conditions (2) and (3) of Definition 8.5.9 come for free over a proper covering.

XI.19 Proposition 11.1.6 (2017: 11.2): faces as ep-groupoids, and Proposition 11.1.8 (2017: 11.3) for $[d]_F$

Faces are tame ep-groupoids (V11.6) `Chapter11/FaceEpGroupoids · EpGroupoid.proposition_11_1_6_faces`. The text: for a face structured tame X, the object and morphism sets of a face X_θ are sub-M-polyfolds with tame induced structures, and X_θ is an ep-groupoid. The proof (pp. 524–525) passes through the faces of the object M-polyfold, and so does the formal one. *Step 1, local pieces.* π maps the face of the object M-polyfold through p into the face of $|X|$ through $|p|$ `Chapter11/FaceEpGroupoids · EpGroupoid.image_faceAt_subset`. For the local pieces of $\{d_X = 1\}$ at x, the faces of $|X|$ through $|x|$ are those through the images of the pieces `Chapter11/FaceEpGroupoids · EpGroupoid.orbitFacesThrough_eq_range`, and for face structured X the map is injective `Chapter11/FaceEpGroupoids · EpGroupoid.injective_orbitFaceAt_pt`. This is the text's count: if x lay in fewer global faces of the object M-polyfold, fewer faces of $|X|$ would pass through $|x|$. So the object M-polyfold is weakly face structured `Chapter11/FaceEpGroupoids · EpGroupoid.IsEpFaceStructured.isWeaklyFaceStructured`. *Step 2, one face near each point.* Every $x \in X_\theta$ lies in exactly one face of the object M-polyfold contained in X_θ `Chapter11/FaceEpGroupoids · EpGroupoid.IsEpFaceStructured.existsUnique_face_subset`, and near x, X_θ is that face `Chapter11/FaceEpGroupoids · EpGroupoid.IsEpFaceStructured.exists_nhds_eq_face`. The text's "disjoint union" is read in this local form, which is what is used. *Step 3, sub-M-polyfold.* A set that near each of its points agrees with a sub-M-polyfold is one `Chapter11/FaceEpGroupoids · MPolyfold.isSubMPolyfold_of_forall_nhds`, and faces are sub-M-polyfolds with tame induced structure (Theorem 2.5.17); so X_θ is a closed `Chapter11/FaceEpGroupoids · EpGroupoid.isClosed_faceObj` saturated sub-M-polyfold `Chapter11/FaceEpGroupoids · EpGroupoid.isSubMPolyfold_faceObj`. *Step 4, the ep-groupoid.* With the morphisms between its points it is an ep-subgroupoid `Chapter11/FaceEpGroupoids · EpGroupoid.isEpSubgroupoid_faceObj` (Proposition 7.1.22) `Chapter11/FaceEpGroupoids · EpGroupoid.faceEpGroupoid`, tame on objects and on morphisms `Chapter11/FaceEpGroupoids · EpGroupoid.isTame_faceEpGroupoid` `Chapter11/FaceEpGroupoids · EpGroupoid.isTame_faceEpGroupoid_mor`, with $d_X(x) = d_{X_\theta}(x) + 1$ `Chapter11/FaceEpGroupoids · EpGroupoid.degIndex_faceEpGroupoid`.

The generalized isomorphisms $[d]_F$ of (11.1) `Chapter11/FaceGeneralizedIso · EPLocalization.EPLoc.proposition_11_1_6_faceIso`. The text: for $X \xleftarrow{\Phi} A \xrightarrow{\Psi} Y$ and a face F of X, $B = \Phi^{-1}(F)$ is a face of A, the saturation C of $\Psi(B)$ is a face of Y, and $F \leftarrow B \rightarrow C$ is a generalized isomorphism by Theorem 10.3.10. *Step 1, restriction.* An sc-smooth functor restricts to ep-subgroupoids $A = G^{-1}(B)$ `Chapter11/FaceGeneralizedIso · EpFunctor.restrictSub`, and so do natural transformations `Chapter11/FaceGeneralizedIso · EpNatTrans.restrictSub`. For an equivalence and saturated B the restriction is full, faithful, essentially surjective and a local sc-diffeomorphism, hence an equivalence by Lemma 10.1.2 `Chapter11/FaceGeneralizedIso · EpFunctor.IsEquivalence.restrictSub`; this is the text's argument. Face structure passes both ways along equivalences `Chapter11/FaceGeneralizedIso · EpFunctor.IsEquivalence.isEpFaceStructured_iff`. *Step 2, the diagram (11.1).* The face as an object of $\mathcal{EP}$ `Chapter11/FaceGeneralizedIso · EPLocalization.faceEP` and the restricted diagram `Chapter11/FaceGeneralizedIso · EPLocalization.Diagram.restrictFace`, with $C = Y_{|\Psi|(\theta_A)}$ (Remark 11.1.5). Refinements and equivalent diagrams restrict to refinements and equivalent diagrams `Chapter11/FaceGeneralizedIso · EPLocalization.Diagram.IsRefinement.restrictFace` `Chapter11/FaceGeneralizedIso · EPLocalization.Diagram.Equiv.restrictFace`, and $|d_F|$ is the restriction of $|d|$ `Chapter11/FaceGeneralizedIso · EPLocalization.Diagram.orbitMap_restrictFace`. *Step 3, the class.* $[d]_F$ `Chapter11/FaceGeneralizedIso · EPLocalization.EPLoc.faceIso` is the class of the restriction of every representative `Chapter11/FaceGeneralizedIso · EPLocalization.EPLoc.homMk_restrictFace_eq_faceIso`. It is a generalized isomorphism `Chapter11/FaceGeneralizedIso · EPLocalization.EPLoc.isGeneralizedIso_faceIso` whose orbit map is the restriction of $|[d]|$ `Chapter11/FaceGeneralizedIso · EPLocalization.EPLoc.orbitMap_faceIso`. The target face is

passed as a set with a proof that it is $f_*\theta$, so that $[f]_F$ and $[g]_F$ have the same type when $f_* = g_*$.

Proposition 11.1.8, the second claim (V11.8) `Chapter11/FaceGeneralizedIso · EPLocalization.EPLoc.proposition_11_1_8_faceIso`. If $|f| = |g|$, then $f_* = g_*$ (§XI.3), and the generalized isomorphisms $F \to f_*F$ and $F \to g_*F$ induce the same map $|F| \to |f_*F|$, both being restrictions of $|f| = |g|$.

XI.20 Proposition 11.1.6 (2017: 11.2): the intersection clause

The clause as printed does not hold as we read it (V11.6) `Chapter11/FaceIntersectionCounterexample · EpGroupoid.FacesMeetInFaces` `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.not_facesMeetInFaces`. The text: if two faces F, G meet, $F \cap G$ is a face in F as well as in G. We read "face in F" in the ep-groupoid X_θ of §XI.19. *The example.* An open subset of a tame M-polyfold, with Part I's open-subset structure, has the same degeneracy index, is tame, and is face structured when the open set is `Chapter11/FaceIntersectionCounterexample · MPolyfold.isTame_restrictOpen` `Chapter11/FaceIntersectionCounterexample · MPolyfold.isFaceStructuredOpen_restrictOpen`; its trivial ep-groupoid is then face structured `Chapter11/FaceIntersectionCounterexample · EpGroupoid.isEpFaceStructured_trivial_restrictOpen`. Take $V = ([0,\infty)^3 \oplus W) \setminus K$ with $K = \{p_0 + p_1 \le 1/4,\ 1 \le p_2 \le 2\}$, a closed block cutting the edge $p_0 = p_1 = 0$ at heights $[1,2]$ `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.V` `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.isEpFaceStructured_XV`. *Step 1.* $\theta_0 = \{p_0 = 0\}$ and $\theta_1 = \{p_1 = 0\}$ are distinct faces `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.isOrbitFace_θ₀` `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.θ₀_ne_θ₁`, connected by paths in them `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.mem_face_of_path`. *Step 2.* They meet in the two pieces $p_2 \in [0,1)$ and $p_2 \in (2,\infty)$ of the edge. A face of X_{θ_0} is the closure of one connected component of its index-one set, and the continuous function p_2 takes values below 1 or above 2 on the edge `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.cF_lt_or_gt`, so the intersection is not one face `Chapter11/FaceIntersectionCounterexample · FaceMeetExample.not_isEpFace_inter`. With $W = 0$ this is a 3-manifold with boundary and corners.

The union form `Chapter11/FaceIntersectionUnion · EpGroupoid.IsEpFaceStructured.faceObj_inter_eq_sUnion` `Chapter11/FaceIntersectionUnion · EpGroupoid.IsEpFaceStructured.facesMeetInUnions`. For distinct faces $\theta \ne \theta'$ of $|X|$, $X_\theta \cap X_{\theta'}$ is the union of the faces of X_θ it contains, and likewise for $X_{\theta'}$ `Chapter11/FaceIntersectionUnion · EpGroupoid.FacesMeetInUnionsOfFaces`. *Step 1, a ray in a tame chart.* A point x of two distinct faces is a limit of points of $F_1 \cap F_2$ with $d_X = 2$: in a tame chart the faces are those of two distinct indices $i \ne j$ of Lemma 4.C, and the points $r(o+ty)$ with $\lambda_i(y) = \lambda_j(y) = 0$ and $\lambda_l(y) = 1$ otherwise have index 2 and lie in both closures `Chapter11/FaceIntersectionUnion · MPolyfold.mem_closure_inter_faces`. *Step 2.* Near a point $y \in X_{\theta'}$ with $d_X(y) = 2$, every point with $d_X = 2$ lies in $X_{\theta'}$ `Chapter11/FaceIntersectionUnion · EpGroupoid.IsEpFaceStructured.exists_nhds_degIndex_two`. *Step 3.* Those points lie in a local piece of $\{d_{X_\theta} = 1\}$ at x. The face of X_θ through that piece contains x, and it lies in $X_{\theta'}$ because $X_{\theta'} \cap \{d_{X_\theta} = 1\}$ is open and closed in $\{d_{X_\theta} = 1\}$.

XI.21 The localization $\mathcal{PC}(E^{-1})$ and I (2021 pp. 561–563)

$\mathcal{PC}(E^{-1})$ (V11.43) `Chapter11/ProperCoveringLocalization · PCLoc` `Chapter11/ProperCoveringLocalization · PCLoc.I`. The text sketches the localization of $\mathcal{PC}$ at E_{PC} "as in the ep-groupoid case" and leaves the details to the reader. *Step 1, maps into weak fibred products.* For functors $L : P \to X$, $R : P \to Z$ and $\alpha : F \circ L \to G \circ R$, $p \mapsto (L(p), \alpha(p), R(p))$ is a functor into $X \times_Y Z$ with $\pi_X \circ \langle L, R\rangle =$

L and $\pi_Z \circ \langle L, R\rangle = R$ on the nose Chapter11/ProperCoveringLocalization · WeakFibredProduct.pairFunctor. Its version for proper coverings, with the square (11.20) for α Chapter11/ProperCoveringLocalization · PC.fibredLift, is an equivalence by two out of three Chapter11/ProperCoveringLocalization · PC.IsEquivalence.of_comp_left Chapter11/ProperCoveringLocalization · PC.isEquivalence_fibredLift, the projection to the side of the equivalence being one (Theorem 11.6.6 (2)). *Step 2, composition.* The composite of $d : F \leftarrow A \rightarrow F'$ and $d' : F' \leftarrow A' \rightarrow F''$ is taken through the weak fibred product $A' \times_{F'} A$ Chapter11/ProperCoveringLocalization · PC.Diagram.comp. The text takes $A \times_{F'} A'$; Theorem 11.6.6 is stated here with the equivalence on the left, and the two products are isomorphic. Its class does not depend on the representatives Chapter11/ProperCoveringLocalization · PC.Diagram.hasCommonRefinement_comp: a single equivalence M with $\Gamma' \circ M \simeq \Gamma$ and $\varepsilon' \circ M \simeq \varepsilon$ gives a common refinement Chapter11/ProperCoveringLocalization · PC.Diagram.hasCommonRefinement_of_map, and Step 1 gives such maps. Associativity and the units hold up to common refinement Chapter11/ProperCoveringLocalization · PC.Diagram.hasCommonRefinement_assoc. *Step 3, I.* I is the identity on objects with $I(\varepsilon) = [F \xleftarrow{1} F \xrightarrow{\varepsilon} F']$. Equivalences go to isomorphisms with inverse $[F' \xleftarrow{\Gamma} F \xrightarrow{1} F]$ Chapter11/ProperCoveringLocalization · PCLoc.isIso_I_map Chapter11/ProperCoveringLocalization · PCLoc.inv_I_map, $[d] = I(\Gamma)^{-1} \circ I(\varepsilon)$ Chapter11/ProperCoveringLocalization · PCLoc.homMk_eq, and the inverse of $[F \xleftarrow{\Gamma} A \xrightarrow{\Gamma'} F']$ for an equivalence Γ' is the reversed class Chapter11/ProperCoveringLocalization · PCLoc.isIso_homMk Chapter11/ProperCoveringLocalization · PCLoc.inv_homMk (G.134). *Witness.* pair $\rightarrow$ point is not an isomorphism of $\mathcal{PC}$, and its image under I is one Chapter11/ProperCoveringLocalization · PCLoc.Examples.not_isIso_pairToPoint_isIso_I_map.

XI.22 Remark 11.6.9 (2017: 11.4): proper strong bundle coverings up to equivalence

The category $\mathcal{SBPC}$ (V11.42) Chapter11/ProperStrongBundleCoverings · SBPC Chapter11/ProperStrongBundleCoverings · SBPC.Hom Chapter11/ProperStrongBundleCoverings · instCategorySBPC. The remark views a strong bundle as a functor, recalls Definition 8.5.9 and describes the category of proper strong bundle coverings: its objects are pairs (A, F) with A a strong bundle functor covering a proper covering F, its morphisms commutative cubes, and its localization is left to the reader. A morphism is a pair of morphisms of $\mathcal{SEP}$ with $A' \circ a = b \circ A$, the top and bottom faces of the cube; the side faces commute because morphisms of $\mathcal{SEP}$ are strong bundle functors. There is a functor to $\mathcal{PC}$ Chapter11/ProperStrongBundleCoverings · SBPC.forget. *The class of equivalences.* The text does not define it. We take the morphisms whose two components are strong bundle equivalences Chapter11/ProperStrongBundleCoverings · SBPC.equivalences; the condition on the base face is then automatic Chapter11/StrongBundleCoveringFibredProduct · SBPC.equivalences_iff. Mathlib's localization gives $\mathcal{SBPC}[E^{-1}]$ with its universal property Chapter11/ProperStrongBundleCoverings · SBPC.Loc Chapter11/ProperStrongBundleCoverings · SBPC.isLocalization_Q Chapter11/ProperStrongBundleCoverings · SBPC.lift Chapter11/ProperStrongBundleCoverings · SBPC.uniq, with functors to $\mathcal{PC}(E^{-1})$ and to $\mathcal{SEP}(F^{-1})$ Chapter11/ProperStrongBundleCoverings · SBPC.toPCLoc Chapter11/ProperStrongBundleCoverings · SBPC.toSEPLocW Chapter11/ProperStrongBundleCoverings · SBPC.toSEPLocV. The identity covering of a strong bundle is an object Chapter11/ProperStrongBundleCoverings · SBPC.ofSEP.

Theorem 11.6.6 for strong bundles Chapter11/StrongBundleCoveringFibredProduct · SBPC.theorem_11_6_6. *Step 1, Definition 8.5.9 over a proper covering.* Condition (3) holds for every strong bundle and every proper covering: $(\psi, w) \mapsto ((F(\psi), s(\psi)), w)$ is a map of pull-backs along the sc-diffeomorphism of Lemma 11.6.1 Chapter11/StrongBundleCoveringPullback · EpStrongBundle.isStrongBundleIso_fibredLift_of_

`isProperCovering`. Condition (2) follows from the local strong bundle isomorphisms of (1) and the even covering `Chapter11/StrongBundleCoveringPullback · StrongBundle.evenlyCovered_of_isStrongBundleIsoOn`. So over a proper covering Definition 8.5.9 is (0) and (1) `Chapter11/StrongBundleCoveringPullback · EpStrongBundle.isProperStrongBundleCovering2021_of`. *Step 2, pull-backs.* The weak fibred product of strong bundles is a pull-back (Chapter 10). The pull-back $(p, w) \mapsto (H(p), A(w))$ of a proper strong bundle covering along an equivalence of proper coverings is one `Chapter11/StrongBundleCoveringPullback · SEP.pullbackCovering` `Chapter11/StrongBundleCoveringPullback · SEP.isProperStrongBundleCovering2021_pullbackCovering`. *Step 3, the theorem.* With natural transformations of morphisms of $\mathcal{SBPC}$, strong bundle natural transformations on both levels with (11.20) for the bases `Chapter11/StrongBundleCoveringFibredProduct · SBPC.NatTrans` `Chapter11/StrongBundleCoveringFibredProduct · SBPC.NaturallyEquivalent`: the weak fibred product `Chapter11/StrongBundleCoveringFibredProduct · SBPC.fibred` is a proper strong bundle covering covering H, its second projection is an equivalence, and $\Gamma \circ \mathrm{pr}_1 \simeq \Lambda \circ \mathrm{pr}_2$ `Chapter11/StrongBundleCoveringFibredProduct · SBPC.fibredNatTrans`.

$\mathcal{SBPC}[E^{-1}]$ by diagrams `Chapter11/StrongBundleCoveringLocalization · SBPCLoc`. Part XII. Sc-Fredholm sections on ep-groupoids (HWZ Chapter 12, §§12.1–12.5)

Chapter 12 opens Part III of the book (Springer 2021, pp. 569–597; the numbers below are the 2021 ones, with the 2017 text's in parentheses). It carries the Fredholm package of Part I (Chapters 5 and 6) from strong bundles over M-polyfolds to strong bundles $(P : W \to X, \mu)$ over ep-groupoids. Everything in Part I lives on one M-polyfold; an ep-groupoid has two, the objects and the morphisms, and a strong bundle over it is a strong bundle over the objects together with an action μ of the morphisms on the fibres. The chapter asks of every Part I notion whether it can be made compatible with the morphisms, and answers by one construction, repeated: build the object on a neighbourhood $U(x)$ carrying the natural representation of the isotropy group G_x, average it over G_x, carry it to the saturation of $U(x)$ by morphisms, and glue the pieces with a partition of unity of the orbit space $|X|$. §12.1 defines sc-Fredholm section functors (Definition 12.1.1 (2017: 12.1)). §12.2 builds auxiliary norms (Definition 12.2.1, Theorem 12.2.2, Definitions 12.2.3, 12.2.4, Proposition 12.2.5, Theorems 12.2.6, 12.2.7 (2017: Definition 12.2, Theorem 12.1, Definitions 12.3, 12.4, Proposition 12.1, Theorems 12.2, 12.3)) and their reflexive variant (Definitions 12.2.8, 12.2.10, Remarks 12.2.9, 12.2.12, Theorems 12.2.11, 12.2.13 (2017: Definitions 12.5, 12.6, Remarks 12.1, 12.2, Theorems 12.4, 12.5)). §12.3 supplies sc$^+$-section functors (Definition 12.3.1, Theorems 12.3.2, 12.3.3, Remarks 12.3.4, 12.3.5, Definition 12.3.6, Proposition 12.3.7, Corollary 12.3.8, Theorem 12.3.9 (2017: Definition 12.7, Theorems 12.6, 12.7, Remarks 12.3, 12.4, Definition 12.8, Proposition 12.2, Corollary 12.1, Theorem 12.8)). §12.4 treats compactness (Definition 12.4.1, Theorem 12.4.2, Definition 12.4.3, Lemma 12.4.4, Proposition 12.4.5, Theorem 12.4.6 (2017: Definition 12.9, Theorem 12.9, Definition 12.10, Lemma 12.1, Proposition 12.3, Theorem 12.10)), and §12.5 the orientation bundle O_f (Lemma 12.5.1, Definition 12.5.2, Theorem 12.5.3, Definition 12.5.4, Remark 12.5.5, Proposition 12.5.6, Theorem 12.5.7 (2017: Lemma 12.2, Definition 12.11, Theorem 12.11, Definition 12.12, Remark 12.5, Proposition 12.4, Theorem 12.12)). The sections of this Part follow the book: §XII.1 is §12.1; §§XII.2–XII.9 are §12.2; §§XII.10–XII.13 are §12.3; §§XII.14–XII.15 are §12.4; §§XII.16–XII.22 are §12.5; §XII.23 collects the hypotheses and their witnesses, §XII.24 what is not formalized and §XII.25 what the formalization taught us.

What is proved, and what is not. Every numbered item of Chapter 12 is formalized, and no statement of Chapter 12 was found not to hold as we read it. What remains open is §12.5's inheritance of Part I's hypotheses (gap G.140) and Theorem 12.5.7 restated for Chapter 10's classes of diagrams (gap G.192).

§12.1. Definition 12.1.1 and the remark after it (regularizing on objects and on morphisms, sc-Fredholm germs) are formalized as printed (§XII.1).

§12.2. Definition 12.2.1 is Definition 8.3.5, and Theorem 12.2.2, Definitions 12.2.3 and 12.2.4 with the remark between them, Proposition 12.2.5 and the good neighbourhood Theorem 12.2.6 are proved as printed (§§XII.2–XII.5). Theorem 12.2.7, the extension of an auxiliary norm from ∂X, is proved as printed for every tame X with paracompact $|X|$ (§XII.6): its global part is the averaging–transport–gluing construction, and its local step is the norm $N'(w) = N(\text{transport of } w \text{ to } \rho(Pw)) + \|h - A(u)h\|_{F_1}$ built from a continuous retraction ρ onto the boundary. Definitions 12.2.8 and 12.2.10 are formalized, Remark 12.2.9 is proved in a stronger form (morphisms preserve mixed convergence) (§XII.7); Theorem 12.2.11 is proved as printed with its three clauses, and Remark 12.2.12 as printed, its clause (3) in a stronger form (§XII.8). Theorem 12.2.13 is proved with the text's hypotheses and with the paracompactness of $|X|$ that its proof takes from Theorem 12.2.11 made explicit; the local step the text settles by inspection is a lemma on the lower semicontinuity of N' under mixed convergence (§XII.9).

§12.3. Definition 12.3.1 is formalized as printed and in a pointwise reading. Theorem 12.3.2 (1) is proved in each of the two consistent readings, Theorem 12.3.2 (2) in the pointwise reading (§XII.10); Theorem 12.3.3 in the pointwise reading, Remarks 12.3.4 and 12.3.5 in explicit forms (§XII.11). Pairing Definition 12.3.1 as printed with Part I's pointwise bump functions would need Part I's open weak-to-pointwise question; this is a reading, not formalization work. Definition 12.3.6 is formalized in its local form and its ep-groupoid form, Proposition 12.3.7 in a stronger form (only the face germs at the point are used) and Corollary 12.3.8 explicitly (§XII.12). Theorem 12.3.9, the extension of sc$^+$-section functors from ∂X with the bound $N(\tilde{s}) \leq \delta$, is proved as printed (§XII.13).

§12.4. Definition 12.4.1, Theorem 12.4.2 and Lemma 12.4.4 are proved (§XII.14). Definition 12.4.3 is formalized, and Proposition 12.4.5 and Theorem 12.4.6 are proved in stronger forms, several of the text's hypotheses being unused (§XII.15).

§12.5. The action of a morphism on linearizations goes through a local strong bundle isomorphism built from its sheet (§XII.16). Lemma 12.5.1 and the action φ_* on orientations are proved with §12.5's standing hypothesis, inherited from Part I, that sc$^+$-sections pass through smooth fibre points (§XII.17). Definition 12.5.2 is Part I's O_f (§XII.18). Theorem 12.5.3 is proved under Part I's hypotheses (tame X, bump functions on the objects, tame germ data), including its last sentence: the local isomorphism of a morphism carries a continuous local orientation near x to one near x', with value $\sigma_* o_x$ at x' (§XII.19). Definition 12.5.4 is formalized, and its continuity clause, read for the topology of O_f, agrees with Part I's continuity of orientations along paths (§XII.20). Remark 12.5.5 is prose. Proposition 12.5.6 is proved in both directions, (□) with the continuity of the orientation (§XII.21). Theorem 12.5.7 is proved for one representative $W \leftarrow V \rightarrow W'$ of a generalized strong bundle isomorphism: (1) with homeomorphisms $|O_f| \rightarrow |O_{f'}|$ over $|X_\infty| \rightarrow |X'_\infty|$, and (2) with continuity in the sense of Definition 12.5.4; its independence of the representative and its functoriality, which the text leaves to the reader, are proved for the data of the diagrams with no further hypothesis (§XII.22).

Narrower items, and why. Theorems 12.3.2 (2) and 12.3.3: the pointwise reading of bump functions, the project's reading of Part I's Definition 5.3.1. Theorem 12.3.2 (1) is restated as two equivalences, one per reading. Theorem 12.5.3, Proposition 12.5.6 (□), Theorem 12.5.7: Part I's hypotheses of Theorem 6.6.17 and the hypothesis that sc$^+$-sections pass through smooth fibre points, both inherited (G.140); Theorem 12.5.7 also by being stated for the data of one diagram rather than for Chapter 10's classes (G.192).

Open gaps. G.140 (Part I's hypotheses carried by §12.5) and G.192 (Theorem 12.5.7 for `SDiagram` and `GenSBMap`), with estimates in §XII.24.

Decisions that shape the chapter.

(1) *Part I on the object M-polyfold.* An sc-Fredholm section functor is an sc-smooth section functor that is a Part I sc-Fredholm section of the object bundle $W \to X$; an auxiliary norm is a Part I auxiliary norm invariant under μ (Definition 8.3.5, Part VIII). Every Part I theorem applies to the objects without restatement, and the chapter's work is the passage through the morphisms.

(2) *Norms are built from Part I norms, and completeness is automatic.* The local norms the text takes from a chart are Part I auxiliary norms (Proposition 5.1.3, Part V). Completeness of a glued fibre norm is not checked by hand: a Part I lemma shows that a continuous fibrewise seminorm satisfying condition (2) of an auxiliary norm is an auxiliary norm (§XII.2). This lemma is used in Theorems 12.2.2, 12.2.7, 12.2.11 and 12.2.13.

(3) *Bump functions in two readings.* Definition 12.3.1 asks for an sc-smooth function "not identically" zero; Part I's Definition 5.3.1 is read pointwise in this project (Part V). Both readings are kept for ep-groupoids and related (§XII.10); the theorems that need a function nonzero at a given point use the pointwise one.

(4) *Orientations live in chart points.* $\mathrm{Lin}(f, x)$ and Or_x^f are Part I's, read in a chosen chart point at x. A morphism φ acts through a local strong bundle isomorphism built from the sheet of φ (`morIso`, the inverse of the text's $\hat{\Phi}$), along which chart points are pulled back and compared (§XII.16). A strong bundle equivalence acts in the same way, through the local isomorphisms it is near each object (§XII.22).

(5) *Continuity of an orientation in two readings.* Part I defines continuity of an orientation section over an open set by propagation along sc-smooth paths (`IsContOrOn`); Definition 12.5.4 asks continuity of $x \mapsto (x, o_x)$ for the topology of O_f. The proofs of §12.5 use the first, and the two are shown to agree (§XII.20), so the statements are given in the text's form.

(6) *Theorem 12.5.7 for the data of diagrams.* A generalized strong bundle isomorphism is a class of diagrams $W \leftarrow V \to W'$ of strong bundle equivalences (Chapter 10, Part X). The theorem is proved for one representative, with the independence of the representative stated through common refinements (Chapter 10's equivalence of diagrams) and the functoriality through the shape of Chapter 10's weak fibred product.

(7) *Hypotheses of Part I are inherited, not added.* Where §12.5 rests on Part I's Theorem 6.6.17, it carries that theorem's hypotheses; they are listed once, in §XII.23, with witnesses.

Morphisms acting on linearizations and orientations. - `Chapter12/MorphismIso`: the local strong bundle isomorphism of a morphism. - `Chapter12/ChartPull`: chart points pulled back along a local strong bundle isomorphism of a bundle to itself. - `Chapter12/OrientationBundleEp`: the generic orientation map of a local isomorphism; $T\varphi$ and $\mu(\varphi,\cdot)$ in chart points; Lemma 12.5.1; φ_* on orientations. - `Chapter12/OrientationOrbit`: orbit spaces of X_∞ and O_f, Definition 12.5.2, the topological part of Theorem 12.5.3, Definition 12.5.4, Proposition 12.5.6 (□) and the invariant lift of (□).

Orientations carried along local isomorphisms. - `Chapter12/ChartPullTwoBundles`: chart points pulled back along a local strong bundle isomorphism between two bundles, and its orientation map. - `Chapter12/SectionPull`, `Chapter12/StabilizedKernelPull`, `Chapter12/PushDataPull`: Part I's push-forward of orientations carried along a local isomorphism: the stabilizing section, the stabilized kernels, the push-forward. - `Chapter12/DyadicPathInduction`: dyadic induction on sc-smooth paths; continuity of orientations is local. - `Chapter12/OrientationLocalCommute`: the transport commutes with a local isomorphism; carried continuous orientations are continuous. - `Chapter12/OrientationGerm`: the orientation map of a local isomorphism depends only on its germ. - `Chapter12/OrientationMorphismContinuity`: the last sentence of Theorem 12.5.3.

Orientability and continuity. - `Chapter12/OrientationFromSection`: Proposition 12.5.6 (□) with continuity. - `Chapter12/ContinuousOrientationSection`: the two readings of continuity of an orientation agree.

Naturality (Theorem 12.5.7). - `Chapter12/OrientationEquivalenceStep`: the local isomorphisms of a strong bundle equivalence, its orientation bijections and their naturality. - `Chapter12/OrientationNaturality`: invariant orientations, the orbit maps, pull-back and push-forward of orientations, Theorem 12.5.7 without topology. - `Chapter12/OrientationEquivalenceContinuity`: pull-back and push-forward keep continuity; Theorem 12.5.7 (2) with Part I's continuity. - `Chapter5/SmoothLevelContinuity`: sc-smooth maps are continuous on the levels and on X_∞. - `Chapter12/OrientationOrbitHomeo`: open orbit maps, the homeomorphisms of one equivalence. - `Chapter12/OrientationTransferTheorem`: Theorem 12.5.7 (1) and (2) as printed. - `Chapter12/OrientationEquivalenceNatural`, `Chapter12/OrientationEquivalenceComp`, `Chapter12/OrientationRepresentativeIndep`: natural equivalences, composition, independence of the representative and functoriality.

Notation. Throughout, $(P : W \to X, \mu)$ is a strong bundle over an ep-groupoid X with source and target maps s, t; B is the underlying Part I strong bundle on objects, $W_{0,1}$ its level-$(0,1)$ part, $\pi : X \to |X|$ the orbit map, G_x the isotropy group, and a natural representation of G_x on $U(x)$ is the one of Theorem 7.1.13 `Chapter7/NaturalRep · theorem_7_1_13`: a group homomorphism $\Phi : G_x \to \mathrm{Diff}_{sc}(U(x))$ and a map $\Gamma : G_x \times U(x) \to \mathbf{X}$ with $s(\Gamma(g,y)) = y$, $t(\Gamma(g,y)) = \Phi(g)(y)$, such that every morphism

between points of $U(x)$ is $\Gamma(g, y)$ for exactly one g. The saturation of a set A of objects is the set of objects joined by a morphism to a point of A; A is saturated if it equals its saturation. ∂X is the set of objects of degeneracy index at least 1; it is saturated, since morphisms are local sc-diffeomorphisms and keep the degeneracy index.

XII.1 Definition 12.1.1 (2017: 12.1) and the remark after it

Definition 12.1.1 (same) `Chapter12/CompactnessEp · EpStrongBundle.definition_12_1_1`, p. 569. Let $(P : W \to X, \mu)$ be a strong bundle over an ep-groupoid. An sc-smooth section functor f (an sc-smooth section of the object bundle with $f(t(\varphi)) = \mu(\varphi, f(s(\varphi)))$ for every morphism φ) is *sc-Fredholm* when it is an sc-Fredholm section of the object bundle in Part I's sense (Definition 3.4.17 as read in Part III): regularizing, and with an sc-Fredholm germ at every smooth point. The Lean declaration is the definition unfolded: it states that the project's predicate `IsScFredholmSectionFunctor` is the conjunction of the section functor property and Part I's sc-Fredholm property for the bundle B. Nothing is added; the text's phrase "for the strong bundle $W \to X$" is the object bundle, since the morphisms carry no further bundle.

The remark after Definition 12.1.1 (explicit), p. 569. The text observes, without proof, that the regularizing property holds on objects and on morphisms, and that the germs are sc-Fredholm. Each is a separate statement.

On objects `Chapter12/CompactnessEp · EpStrongBundle.remark_12_1_1_regularizing_obj`. If $x \in X_m$ and $f(x) \in W_{m,m+1}$, then $x \in X_{m+1}$. This is Part I's regularizing property of f on the object bundle, read off the definition.

On morphisms `Chapter12/CompactnessEp · EpStrongBundle.remark_12_1_1_regularizing_mor`. The text writes $f(\varphi)$ for a morphism φ. A section functor gives no vector over a morphism directly; the formal statement reads $f(\varphi)$ as the section $\varphi \mapsto (\varphi, f(s(\varphi)))$ of the pull-back bundle $\mathbf{X}\,{}_s\!\times_P W \to \mathbf{X}$, the bundle over the morphism space whose fibre over φ is $W_{s(\varphi)}$. The statement: if $\varphi \in \mathbf{X}_m$ and $f(\varphi)$ lies on level $(m, m+1)$ of the pull-back bundle, then $\varphi \in \mathbf{X}_{m+1}$. *Step 1.* The projection of the pull-back bundle to W is a strong bundle map, so it keeps the bi-levels; $f(s(\varphi))$ lies in $W_{m,m+1}$. *Step 2.* By the regularizing property on objects, $s(\varphi) \in X_{m+1}$. *Step 3.* The levels of the morphism M-polyfold are those of the sources, since s is a local sc-diffeomorphism; so $\varphi \in \mathbf{X}_{m+1}$.

Germs `Chapter12/CompactnessEp · EpStrongBundle.remark_12_1_1_germ`. At a smooth object x, the germ of f at x is an sc-Fredholm germ. This is the second clause of Part I's definition, read at x.

No hypothesis is added. The definition has a witness in every Part I sc-Fredholm section of a trivial ep-groupoid (an M-polyfold with only identity morphisms), where the functor property is empty.

XII.2 Definition 12.2.1 (2017: 12.2): auxiliary norms, and completeness for free

Definition 12.2.1 (same) `Chapter8/Book2021 · EpStrongBundle.IsAuxNorm`, p. 570. The text recalls Definition 8.3.5, and the formalization uses that declaration unchanged: an auxiliary norm is a Part I auxiliary norm $N : W_{0,1} \to [0, \infty)$ of the object bundle (Definition 5.1.1, Part V: continuous, a complete norm on each fibre, and condition (2): if $P(h_k) \to x$ in X and $N(h_k) \to 0$, then $h_k \to 0_x$ in $W_{0,1}$) with $N(\mu(\varphi, k)) = N(k)$

for every morphism φ and every $k \in W_{0,1}$ over $s(\varphi)$. In the project N is a function on all of W, and "$N(k) \le C$" is Part I's relation, which fails off $W_{0,1}$ (equivalently, $N = \infty$ there).

Completeness is automatic (extra, Part I) `Chapter12/AuxNormEp · StrongBundle.isAuxNorm_of_tendsto`. The text asserts, of each glued norm it builds, that it is complete on the fibres. The formal proof replaces these assertions by one lemma about Part I's Definition 5.1.1. Call $N : W \to [0,\infty)$ a *fibre seminorm* if its restriction to each fibre $W_{0,1}|_x$ is a seminorm `Chapter12/AuxNormEp · StrongBundle.IsFiberSeminorm`, and say it satisfies *condition (2)* if $P(h_k) \to x$, $N(h_k) \to 0$ imply $h_k \to 0_x$ in $W_{0,1}$ `Chapter12/AuxNormEp · StrongBundle.TendstoZeroOne`. The lemma: a continuous fibre seminorm on $W_{0,1}$ satisfying condition (2) is an auxiliary norm.

Proof. Fix x and a strong bundle chart Φ around x with fibre F, and write $|w|_1 = \|\mathrm{pr}_2 \Phi[1](w)\|_{F_1}$ for w over points near x; on each fibre this is a complete norm, because $\Phi[1]$ is a linear isomorphism of the fibre onto a closed subspace (the image of the fibre projection $A(u)$) of F_1.

Step 1, an upper bound. By continuity of N at 0_x there is $\delta > 0$ and a neighbourhood O of x with $N(w) \le 1$ when $P(w) \in O$ and $|w|_1 \le \delta$. By homogeneity, $N(w) \le \delta^{-1}|w|_1$ for $P(w) \in O$. (In Lean: `StrongBundle.exists_le_mul_norm_liftOne`.)

Step 2, a lower bound `Chapter12/AuxNormEp · StrongBundle.exists_norm_liftOne_le_of_tendsto`. Suppose no $c > 0$ and neighbourhood of x satisfy $|w|_1 \le c\,N(w)$. Then there are w_k over points $P(w_k) \to x$ with $|w_k|_1 > k\,N(w_k)$; rescale so that $|w_k|_1 = 1$. Then $N(w_k) < 1/k \to 0$, and condition (2) gives $w_k \to 0_x$ in $W_{0,1}$, hence $|w_k|_1 \to 0$ by continuity of the chart on level 1, against $|w_k|_1 = 1$.

Step 3, positivity and completeness. By Step 2, $N(w) = 0$ forces $|w|_1 = 0$, so N is a norm on each fibre. By Steps 1 and 2 it is equivalent on each fibre near x to the complete norm $|\cdot|_1$, hence complete (`complete_of_bounds`). The other two clauses of Definition 5.1.1, continuity and condition (2), are hypotheses. □

The same lemma in local form: a *local auxiliary norm* on an open U asks continuity on $W_{0,1}|U$, the seminorm property over U and condition (2) for limits $x \in U$ only `Chapter12/AuxNormEp · StrongBundle.IsLocalAuxNorm`. The local norms of all constructions below are local auxiliary norms, and the glued norms are proved to be auxiliary norms by the lemma. The step is a strengthening of Part I's toolkit: it applies equally to Part I's Proposition 5.1.3, though Part I proves that proposition directly.

XII.3 Theorem 12.2.2 (2017: 12.1): auxiliary norms exist

Theorem 12.2.2 (same) `Chapter12/AuxNormEp · EpStrongBundle.theorem_12_2_2`, p. 570: every strong bundle $(P : W \to X, \mu)$ over an ep-groupoid with paracompact orbit space $|X|$ admits an auxiliary norm. The same for a bundled object of the category $\mathcal{SEP}$ of strong bundles over ep-groupoids `Chapter12/AuxNormEp · SEP.theorem_12_2_2`, a one-line wrapper. The hypotheses are the text's; the conclusion is Definition 12.2.1 in full.

The proof follows the text's three steps, average, transport, glue; the formal construction is a chain of definitions in `AuxNormEp`, each with its lemma.

Step 0: the lifted action on $W_{0,1}$. The strong bundle action μ is defined on the pull-back $\mathbf{X}_s \times_P W$. For a function α from objects to morphisms with $s(\alpha(y)) = y$, define $\alpha * w = \mu(\alpha(P(w)), w)$ `Chapter12/AuxNormEp · EpStrongBundle.actOne`. When α is sc-smooth on an open set, $\alpha*$ is an sc-smooth map of $W[1]$ there, so it preserves $W_{0,1}$ and is continuous on it. Along a natural representation, $g * w = \mu(\Gamma(g, P(w)), w)$ is a group action of G_x on $W|U(x)$: $1 * w = w$ `Chapter12/AuxNormEp · EpStrongBundle.`

actOne_Γ_one because $\Gamma(1,y) = 1_y$, and $(gh) * w = g * (h * w)$ Chapter12/AuxNormEp · EpStrongBundle.actOne_Γ_mul because $\Gamma(gh,y) = \Gamma(g,\Phi(h)y) \circ \Gamma(h,y)$ by the uniqueness clause of Theorem 7.1.13 and μ respects composition. Restricted to one fibre, $g*$ is the linear map $\mu(\Gamma(g,y),\cdot) : W_y \to W_{\Phi(g)y}$ Chapter12/AuxNormEp · EpStrongBundle.actFiber.

Step 1: average. Fix x, a natural representation on $U(x)$ and a local auxiliary norm M on $U(x)$. Put

$$\bar{M}(w) = \frac{1}{|G_x|} \sum_{g \in G_x} M(g * w)$$

Chapter12/AuxNormEp · EpStrongBundle.avgNorm. *Invariance* Chapter12/AuxNormEp · EpStrongBundle.avgNorm_actOne: $\bar{M}(h * w) = \bar{M}(w)$, by reindexing the sum through $g \mapsto gh$ and Step 0. *A local auxiliary norm* Chapter12/AuxNormEp · EpStrongBundle.isLocalAuxNorm_avgNorm. Continuity: each term $M \circ (g*)$ is continuous, as a composite of continuous maps over $U(x)$, and $\Phi(g)$ maps $U(x)$ into itself. Seminorm: each term is a seminorm composed with a linear fibre map. Condition (2): if $P(w_k) \to y \in U(x)$ and $\bar{M}(w_k) \to 0$, then the term with $g = 1$ satisfies $M(w_k) \le |G_x|\,\bar{M}(w_k) \to 0$, since all terms are nonnegative, and condition (2) for M gives $w_k \to 0_y$.

Step 2: transport to the saturation. Let $S = \mathrm{sat}(U(x))$ be the set of objects y admitting a morphism φ with $s(\varphi) = y$ and $t(\varphi) \in U(x)$ Chapter12/AuxNormEp · EpGroupoid.satSet. Choose one such morphism φ_y for every $y \in S$ Chapter12/AuxNormEp · EpGroupoid.selMor (a choice function; no regularity is asked) and put

$$T(w) = \bar{M}(\mu(\varphi_{P(w)}, w)) \text{ for } P(w) \in S, \qquad T(w) = 0 \text{ otherwise}$$

Chapter12/AuxNormEp · EpStrongBundle.transNorm.

Independence of the choice Chapter12/AuxNormEp · EpStrongBundle.transNorm_eq_of. If ψ is another morphism from y into $U(x)$, then $\psi \circ \varphi_y^{-1}$ is a morphism between points of $U(x)$, hence equals $\Gamma(g, t(\varphi_y))$ for a unique $g \in G_x$; so $\mu(\psi, w) = g * \mu(\varphi_y, w)$ and $\bar{M}(\mu(\psi,w)) = \bar{M}(\mu(\varphi_y,w))$ by invariance. At this point the text invokes the good neighbourhood property (5) of Theorem 12.2.6; the invariance of $\bar{M}$ makes it unnecessary, because what has to be compared are two morphisms into $U(x)$, and any two differ by an element of G_x.

Continuity Chapter12/AuxNormEp · EpStrongBundle.continuousOn_transNorm. Fix w_0 over $y_0 \in S$ and its chosen morphism φ_0. Since s is a local sc-diffeomorphism, there is a local inverse ρ of s on a neighbourhood O of y_0 with $\rho(y_0) = \varphi_0$ (`X.isLocalScDiffeo_src`); shrinking O, $t(\rho(y)) \in U(x)$ for $y \in O$, so $O \subset S$. For w over O, $\rho(P(w))$ is a morphism from $P(w)$ into $U(x)$, so by independence of the choice $T(w) = \bar{M}(\rho * w)$ near w_0, and this is continuous by Step 0.

Condition (2) Chapter12/AuxNormEp · EpStrongBundle.tendsto_transNorm. Let $P(w_k) \to y_0 \in S$ and $T(w_k) \to 0$. With ρ as above, $v_k = \rho * w_k$ lies over $t(\rho(P(w_k))) \to t(\varphi_0) \in U(x)$ and $\bar{M}(v_k) = T(w_k) \to 0$ eventually; condition (2) for $\bar{M}$ gives $v_k \to 0$. To bring this back, let τ be a local inverse of t near φ_0, and $\alpha' = \mathrm{inv} \circ \tau$, an sc-smooth local section of s near $t(\varphi_0)$; then $w_k = \alpha' * v_k$ eventually, by μ_inv_μ and the identity $\tau(t(\rho(y))) = \rho(y)$, and $\alpha'*$ is continuous with $\alpha' * 0 = 0$. So $w_k \to 0_{y_0}$.

Seminorm Chapter12/AuxNormEp · EpStrongBundle.isFiberSeminorm_transNorm: on the fibre over $y \in S$, T is the seminorm $\bar{M}$ composed with the linear map $\mu(\varphi_y, \cdot)$; off S it is 0. So T is a local auxiliary norm on S Chapter12/AuxNormEp · EpStrongBundle.isLocalAuxNorm_transNorm, and it is *invariant under every morphism* Chapter12/AuxNormEp · EpStrongBundle.transNorm_μ: for $\psi : y \to y'$, $y \in S$ iff $y' \in S$, and $\varphi_{y'} \circ \psi$ is a morphism from y into $U(x)$, so $T(\mu(\psi, w)) = \bar{M}(\mu(\varphi_{y'} \circ \psi, w)) = T(w)$ by independence of the choice.

Step 3: glue. *Partitions of unity of X* (Definition 12.2.3, §XII.4) are pulled back from $|X|$. For each object x the set $\pi(S_x)$, $S_x = \mathrm{sat}(U(x))$, is open in $|X|$ because π is open (Proposition 7.1.8), and these sets cover $|X|$. Since $|X|$ is paracompact and Hausdorff, there is a partition of unity $(\beta_i)_{i\in I}$ of $|X|$ subordinate to a subcover $(\pi(S_{x_i}))$. Put

$$N(w) = \sum_{i\in I} \beta_i(\pi(P(w)))\, T_i(w)$$

`Chapter12/AuxNormEp · EpStrongBundle.glueNorm`, a locally finite sum. A term vanishes where $\pi(P(w)) \notin \operatorname{supp}\beta_i$ `Chapter12/AuxNormEp · EpStrongBundle.partition_eq_zero_of_not_mem` and all terms are nonnegative `Chapter12/AuxNormEp · EpStrongBundle.glue_term_nonneg`.

N is an auxiliary norm `Chapter12/AuxNormEp · EpStrongBundle.isAuxNorm_glueNorm`. By the lemma of §XII.2 three things must be checked, and invariance.

- *Continuity.* Near any w_0, only finitely many $\beta_i \circ \pi \circ P$ are nonzero (local finiteness, pulled back through the continuous $\pi \circ P$), so N is a finite sum there (`continuous_finsum`). Each term is continuous: where $\pi(P(w)) \in \operatorname{supp}\beta_i \subset \pi(S_{x_i})$, $P(w)$ lies in the open saturated S_{x_i}, on which T_i is continuous; outside the closed set $\pi^{-1}(\operatorname{supp}\beta_i)$ the term is identically 0 nearby.
- *Seminorm.* A nonnegative combination of seminorms on each fibre.
- *Condition (2).* Let $P(w_k) \to y$ and $N(w_k) \to 0$. Choose i with $\beta_i(\pi(y)) > 0$. Then $\beta_i(\pi(P(w_k))) \geq \beta_i(\pi(y))/2$ eventually, so $T_i(w_k) \leq 2N(w_k)/\beta_i(\pi(y)) \to 0$, the term being squeezed below the sum by nonnegativity. Since $\pi(y) \in \operatorname{supp}\beta_i \subset \pi(S_{x_i})$, $y \in S_{x_i}$, and condition (2) for T_i gives $w_k \to 0_y$.
- *Invariance.* $\beta_i \circ \pi$ is constant along morphisms (`π_src_eq_π_tgt`), and each T_i is invariant.

The ingredients are all prior results. The local norms M_i are the restrictions to $U(x_i)$ of one Part I auxiliary norm of the object bundle `Chapter5/AuxNorm · proposition_5_1_3_exists`, which Part I provides on the object M-polyfold. The natural representations come from Theorem 7.1.13 at every object, with $U(x)$ inside X. The partition of unity exists because $|X|$ is paracompact (the hypothesis) and Hausdorff (Proposition 7.1.8; `PartitionOfUnity.exists_isSubordinate`); Theorem 7.3.1 `Chapter7/OrbitTopology · theorem_7_3_1_metrizable` supplies the regularity that the subordinate partition needs. □

Where the formal proof departs from the text. (a) The text takes the local norm in a strong bundle chart as $\|\mathrm{pr}_2\Psi(\cdot)\|_{F_1}$; a Part I auxiliary norm restricted to $U(x)$ serves equally and comes with condition (2). (b) Completeness of $\bar{M}$, T and N is not checked separately; the lemma of §XII.2 gives it. (c) Property (5) of Theorem 12.2.6 is not used; invariance under G_x replaces it. (d) The text's "N is continuous since the sum is locally finite" needs that each term is continuous where its coefficient is nonzero, which is the continuity of T_i on the open saturation; this is proved through local inverses of s.

XII.4 Definitions 12.2.3, 12.2.4 (2017: 12.3, 12.4) and Proposition 12.2.5 (2017: 12.1): partitions of unity

Definition 12.2.3 (same) `Chapter12/AuxNormEp · EpGroupoid.IsContPartitionOfUnity`, p. 570. A continuous partition of unity of the ep-groupoid X, indexed by Λ, is a family of continuous functions $\beta_\lambda : X \to [0,1]$ on the objects with (1) $\beta_\lambda(s(\varphi)) = \beta_\lambda(t(\varphi))$ for every morphism φ; (2) local finiteness through saturated sets: every object has a saturated open neighbourhood meeting the supports of only finitely many β_λ; (3) $\sum_\lambda \beta_\lambda = 1$. Supports are closures in X. The text's preamble has $|X|$ paracompact; the definition does not use it, and it is not a field, but a hypothesis of Proposition 12.2.5.

The remark after Definition 12.2.3 (same), p. 570, has two directions.

From $|X|$ to X `Chapter12/AuxNormEp · EpGroupoid.isContPartitionOfUnity_comp_π`. If $(\hat\beta_\lambda)$ is a continuous partition of unity of $|X|$, then $\beta_\lambda = \hat\beta_\lambda \circ \pi$ is one of X. (1) holds because $\pi(s(\varphi)) = \pi(t(\varphi))$. Continuity: π is continuous. (2): a point $\pi(x)$ has an open O meeting finitely many $\operatorname{supp}\hat\beta_\lambda$; $\pi^{-1}(O)$ is open and saturated, and $\operatorname{supp}(\hat\beta_\lambda \circ \pi) \subset \pi^{-1}(\operatorname{supp}\hat\beta_\lambda)$, so it meets finitely many supports. (3) is pointwise.

From X to $|X|$ `Chapter12/AuxNormEp · EpGroupoid.IsContPartitionOfUnity.descend`. A continuous partition of unity of X descends: by (1) each β_λ is constant on orbits, so $\beta_\lambda = \hat\beta_\lambda \circ \pi$ for a unique $\hat\beta_\lambda$ on $|X|$. Continuity of $\hat\beta_\lambda$ holds because π is an open surjection, hence a quotient map. Local finiteness on $|X|$: for a saturated open U meeting finitely many supports, $\pi(U)$ is open, by openness of π (Proposition 7.1.8), and $\pi(U)$ meets $\operatorname{supp}\hat\beta_\lambda$ only if U meets $\operatorname{supp}\beta_\lambda$; for the latter, a point of $\pi(U) \cap \{\hat\beta_\lambda \neq 0\}$ lifts into U because U is saturated, and $\pi^{-1}(\operatorname{cl}\{\hat\beta_\lambda \neq 0\}) = \operatorname{cl}\pi^{-1}\{\hat\beta_\lambda \neq 0\}$ for the open map π.

Definition 12.2.4 (same) `Chapter12/AuxNormEp · EpGroupoid.IsContPartitionOfUnity.IsSubordinate`, p. 571. For a family (U_λ) of saturated open sets covering X, a continuous partition of unity (β_λ) is subordinate if $\operatorname{supp}\beta_\lambda \subset U_\lambda$ for every λ, the supports taken in X.

Proposition 12.2.5 (same) `Chapter12/AuxNormEp · EpGroupoid.proposition_12_2_5`, p. 571. If $|X|$ is paracompact, every cover (U_λ) of X by saturated open sets has a subordinate continuous partition of unity, indexed by the same Λ.

Proof, the text's. *Step 1.* The sets $\pi(U_\lambda)$ are open in $|X|$ because π is open, and cover $|X|$ because π is surjective. *Step 2.* $|X|$ is Hausdorff (Proposition 7.1.8) and paracompact, hence normal, and admits a partition of unity $(\hat\beta_\lambda)$ subordinate to $(\pi(U_\lambda))$, with the same index set (`PartitionOfUnity.exists_isSubordinate`). *Step 3.* By the first direction of the remark, $\beta_\lambda = \hat\beta_\lambda \circ \pi$ is a continuous partition of unity of X. *Step 4, subordination* `Chapter12/AuxNormEp · EpGroupoid.isSubordinate_comp_π`: $\operatorname{supp}\beta_\lambda \subset \pi^{-1}(\operatorname{supp}\hat\beta_\lambda) \subset \pi^{-1}(\pi(U_\lambda)) = U_\lambda$, the last equality because U_λ is saturated, and the first because π^{-1} of a closed set is closed and contains $\{\beta_\lambda \neq 0\}$. □

No hypothesis is added, and nothing in the text's argument is replaced. The construction of §XII.3 uses Proposition 12.2.5 in the form of Steps 1–4 directly, with U_λ the saturations $\operatorname{sat}(U(x))$.

XII.5 Theorem 12.2.6 (2017: 12.2): good neighbourhoods

Theorem 12.2.6 (same) `Chapter12/GoodNeighborhood · EpGroupoid.theorem_12_2_6`, pp. 571–572. Let $(P : W \to X, \mu)$ be a strong bundle over an ep-groupoid and x an object. There are open sets $U'(x) \subset U''(x)$ containing x and a natural representation R of G_x with domain $U''(x)$ such that:

1. $\overline{U'(x)} \subset U''(x)$;
2. $U'(x)$ is invariant under the natural representation: $\Phi(g)(U'(x)) = U'(x)$ for all $g \in G_x$;
3. $U''(x)$ lies in the base of one strong bundle chart of the atlas, which restricted to $P^{-1}(U''(x))$ is a strong bundle isomorphism onto a local model;
4. for every sequence of morphisms φ_k with $s(\varphi_k) \in \overline{U''(x)}$ and $t(\varphi_k) \to z$, a subsequence converges to a morphism φ with $s(\varphi) \in \overline{U''(x)}$ and $t(\varphi) = z$;
5. $(\pi^{-1}(\pi(U'(x))) \setminus U'(x)) \cap \overline{U''(x)} = \emptyset$: a point of $\overline{U''(x)}$ in the saturation of $U'(x)$ lies in $U'(x)$.

The text proves the theorem by pointing to Chapter 7; the formal proof assembles it in four steps.

Step 1, properness. Since X is an ep-groupoid, x has an open neighbourhood V_0 such that $t : s^{-1}(\overline{V_0}) \to X$ is proper (`X.exists_isProperMap`, the properness clause of the definition of an ep-groupoid). A strong

bundle chart c of the atlas contains x in its base. Theorem 7.1.13 gives a natural representation R_0 of G_x on a domain inside $V_0 \cap \operatorname{dom} c$ `Chapter7/NaturalRep · theorem_7_1_13`.

Step 2, two shrinkings. Choose a closed neighbourhood t_1 of x inside $R_0.U$, and shrink the natural representation to an invariant domain inside the interior of t_1 `Chapter7/NaturalRep · exists_naturalRep_shrink`; this is R_1, with domain $U''(x) = R_1.U$ and $\overline{R_1.U} \subset t_1 \subset R_0.U$. Repeat with R_1 in place of R_0 to get R_2 with $\overline{R_2.U} \subset R_1.U$, and put $U'(x) = R_2.U$. The shrinking lemma keeps the group homomorphism Φ (restricted), so $\Phi_2(g) = \Phi_1(g)|U'$ and (1) holds. *(2).* $U'(x)$ is the domain of the natural representation R_2, which is invariant under its own Φ; the image of the domain under $\Phi(g)$ is the domain `Chapter12/GoodNeighborhood · EpGroupoid.NaturalRep.image_Φ_eq`, because $\Phi(g)$ maps the domain into itself and so does $\Phi(g^{-1}) = \Phi(g)^{-1}$. *(3).* $U''(x) \subset R_0.U \subset \operatorname{dom} c$; the chart is a member of the atlas, so its restriction is a strong bundle isomorphism onto its local model.

Step 3, (4) `Chapter12/GoodNeighborhood · EpGroupoid.exists_subseq_of_isProperMap`. The general lemma: if $t : s^{-1}(\overline{V_0}) \to X$ is proper, $A \subset \overline{V_0}$ is closed, $s(\varphi_k) \in A$ and $t(\varphi_k) \to z$, then some subsequence $\varphi_{\sigma(k)}$ converges to a ψ with $s(\psi) \in A$, $t(\psi) = z$. *Proof.* $K = \{z\} \cup \{t(\varphi_k)\}$ is compact, as a convergent sequence with its limit; its preimage under the proper map is compact and contains every φ_k. The morphism space is metrizable, so compact sets are sequentially compact, and a subsequence converges to some ψ in the preimage. Continuity of s and closedness of A give $s(\psi) \in A$; continuity of t and uniqueness of limits give $t(\psi) = z$. Applied with $A = \overline{U''(x)} \subset \overline{V_0}$, this is (4).

Step 4, (5). Let $y \in \overline{U''(x)}$ with $\pi(y) = \pi(z)$ for some $z \in U'(x)$. There is a morphism $\varphi : z \to y$. Both $z \in U'(x) \subset R_0.U$ and $y \in \overline{U''(x)} \subset R_0.U$, so by the uniqueness clause of Theorem 7.1.13, $\varphi = \Gamma(g, z)$ for a unique $g \in G_x$, and $y = t(\varphi) = \Phi(g)(z)$. By (2), $\Phi(g)(z) \in U'(x)$. So $y \in U'(x)$. □

The first shrinking serves (5): it puts $\overline{U''(x)}$ inside the domain $R_0.U$ of a natural representation, on which every morphism is a $\Gamma(g, \cdot)$. No hypothesis is added. Property (5) is not used in the construction of §XII.3 (§XII.3, Step 2); Theorem 12.2.6 is used through (3) and (4) in the compactness arguments of §§XII.14–XII.15 and in later chapters.

XII.6 Theorem 12.2.7 (2017: 12.3): extension of auxiliary norms from the boundary

Theorem 12.2.7 (same) `Chapter12/AuxNormLocalExtension · EpStrongBundle.theorem_12_2_7`, pp. 574–575. Let $(P : W \to X, \mu)$ be a strong bundle over a tame ep-groupoid X with paracompact $|X|$, and N an auxiliary norm of $W_{0,1}|\partial X$ (Definition 12.2.1 over ∂X). Then there is an auxiliary norm $\tilde{N}$ of W with $\tilde{N} = N$ over ∂X. The hypotheses are the text's.

Auxiliary norms over a subset. For a set A of objects, *an auxiliary norm over* A `Chapter12/AuxNormExtension · EpStrongBundle.IsAuxNormOn` is a function N on $W_{0,1}$ that is continuous on $W_{0,1}|A$, a complete norm on each fibre over A, satisfies condition (2) for sequences w_k over A whose base points converge to a point of A, and is invariant where defined: $N(\mu(\varphi, k)) = N(k)$ when $P(k) = s(\varphi) \in A$. The text's N is a function on $W_{0,1}|\partial X$; a function on all of $W_{0,1}$ with conditions over ∂X only is the same datum, its values off ∂X being irrelevant. A global auxiliary norm restricts to one over any A `Chapter12/AuxNormExtension · EpStrongBundle.IsAuxNorm.isAuxNormOn`. Morphisms preserve ∂X in both directions: $t(\varphi) \in \partial X$ iff $s(\varphi) \in \partial X$ `Chapter12/AuxNormExtension · EpGroupoid.tgt_mem_boundary_iff`, because $t \circ (s|_{\text{sheet}})^{-1}$ is a local sc-diffeomorphism and keeps the degeneracy index; so $X \setminus \partial X$ is open `Chapter12/`

AuxNormExtension · EpGroupoid.isOpen_compl_boundary (the degeneracy index is upper semicontinuous) and saturated.

The proof has two parts: a global part, the construction of §XII.3 with local extensions near the boundary as input, and a local step that constructs those local extensions.

The global part

The local extensions Chapter12/AuxNormExtension · EpStrongBundle.HasLocalExtensions: say N *has local extensions* if every $x \in \partial X$ has an open $V \ni x$ and a local auxiliary norm M on V (§XII.2) with $M = N$ on $W_{0,1}|(V \cap \partial X)$.

The global part Chapter12/AuxNormExtension · EpStrongBundle.theorem_12_2_7_hyp: if $|X|$ is paracompact and N is an auxiliary norm over ∂X with local extensions, then there is an auxiliary norm $\tilde{N}$ of W with $\tilde{N} = N$ over ∂X. Tameness is not used here.

Step 1, data at each point. For every object x choose a natural representation R_x and a local auxiliary norm M_x on its domain: - if $x \in \partial X$: the local extension M on $V \ni x$, and R_x from Theorem 7.1.13 with domain inside V; $M_x = M$ restricted Chapter12/AuxNormExtension · StrongBundle.IsLocalAuxNorm.mono, still equal to N over $R_x.U \cap \partial X$; - if $x \notin \partial X$: R_x with domain inside the open set $X \setminus \partial X$, and $M_x = N_0$, the restriction of a fixed Part I auxiliary norm N_0 of the object bundle (Proposition 5.1.3).

Step 2, average and transport, as in §XII.3: $\bar{M}_x$ is G_x-invariant on $R_x.U$, and $T_x = \mathrm{transNorm}(R_x, \bar{M}_x)$ is a local auxiliary norm on $S_x = \mathrm{sat}(R_x.U)$, invariant under morphisms.

Step 3, glue. A partition of unity (β_x) of $|X|$ subordinate to $(\pi(S_x))_x$, which cover $|X|$ (every $\pi(y)$ lies in $\pi(S_y)$), and $\tilde{N} = \sum_x (\beta_x \circ \pi \circ P)\, T_x$. By §XII.3, $\tilde{N}$ is an auxiliary norm of W.

Step 4, $\tilde{N} = N$ over ∂X. Fix w over $y \in \partial X$. The claim is that every term is $\beta_x(\pi(y))\, N(w)$; then $\tilde{N}(w) = (\sum_x \beta_x(\pi(y)))N(w) = N(w)$. If $\beta_x(\pi(y)) = 0$ there is nothing to prove. Otherwise $\pi(y) \in \mathrm{supp}\, \beta_x \subset \pi(S_x)$, so $y \in S_x$ (S_x is saturated), and there is a morphism $\varphi : y \to y'$ with $y' \in R_x.U$. - *x is a boundary point.* Otherwise $R_x.U \subset X \setminus \partial X$, but $y' = t(\varphi) \in \partial X$ because $y \in \partial X$; contradiction. - *The transported vector.* $T_x(w) = \bar{M}_x(v)$ with $v = \mu(\varphi_y, w)$ for the selected morphism φ_y; v lies over a point of $R_x.U \cap \partial X$, and $N(v) = N(w)$ by the invariance of N over ∂X. - *Each term of the average is $N(w)$.* For $g \in G_x$, $g * v$ lies over $\Phi(g)(P(v)) \in R_x.U$, again in ∂X; there $M_x = N$, so $M_x(g * v) = N(g*v) = N(v) = N(w)$, by invariance of N under the morphism $\Gamma(g, P(v))$. - *The average of constants.* $\bar{M}_x(v) = |G_x|^{-1} \cdot |G_x| \cdot N(w) = N(w)$; G_x is finite and nonempty.

So $\beta_x(\pi(y))T_x(w) = \beta_x(\pi(y))N(w)$ for every x, and $\tilde{N}(w) = N(w)$. □

The text's argument for Step 4 is the same in substance: its local norms near boundary points restrict to N, and its interior pieces are supported away from ∂X. The formal proof records why interior pieces do not reach ∂X: their saturations miss ∂X because ∂X is saturated.

A property of this Lean statement. The global part takes the local extensions as the hypothesis `HasLocalExtensions`; it is valid as stated and serves as the global half of Theorem 12.2.7, the hypothesis being discharged below for every tame X. Its own satisfiability witness Chapter12/AuxNormExtension · EpStrongBundle.theorem_12_2_7_hyp_witness: over every ep-groupoid with paracompact $|X|$ some N satisfies both hypotheses, the restriction of a norm of Theorem 12.2.2, since a global auxiliary norm has itself as local extension Chapter12/AuxNormExtension · EpStrongBundle.hasLocalExtensions_of_isAuxNorm. This witness is a consistency check only: in it the extension problem is solved by the global norm itself.

The local step

The local step is a statement about one strong bundle over a tame M-polyfold, the object bundle; it does not see the morphisms. The text takes a tame local strong bundle model $K = R(U \lhd F) \to O$ at a boundary point, the tame retraction r of its base, and defines on $K|O$ a norm by the formula $N(rq(u), A(rq(u))w) + \|w - A(rq(u))w\|_{F_1}$, with q a shift onto the boundary. The formal proof splits this into a retraction onto the boundary, which lives in a tame chart of the base, and a norm formula, which can be evaluated in any strong bundle chart.

The retraction onto the boundary (extra, Part I) `Chapter12/AuxNormLocalExtension · MPolyfold.exists_retraction_boundary`. Let X be a tame M-polyfold and $x_0 \in \partial X$. There are an open $V \ni x_0$ and a map $\rho : X \to X$, continuous on V, with $\rho(V) \subset \partial X$ and $\rho(y) = y$ for $y \in V \cap \partial X$.

The coordinates. Let C be a partial quadrant with a presentation $T : C \cong [0,\infty)^n \oplus H$ (a linear isomorphism of the ambient space carrying C onto the standard partial quadrant), and write points as (t, h), $t \in [0,\infty)^n$. Define

$$\tau(t,h) = \min(t_1, \dots, t_n), \qquad q(t,h) = (t,h) - \tau(t,h)\,(1, \dots, 1, 0)$$

`Chapter12/AuxNormLocalExtension · minCoord` `Chapter12/AuxNormLocalExtension · boundaryShift`, read through T, for $n \geq 1$. The properties: - τ and q are continuous `Chapter12/AuxNormLocalExtension · continuous_minCoord` `Chapter12/AuxNormLocalExtension · continuous_boundaryShift`, as a minimum of finitely many coordinates and an affine expression in it; - the coordinates of q are $t_i - \tau$ `Chapter12/AuxNormLocalExtension · coord_boundaryShift`, and $\tau \leq t_i$ for all i `Chapter12/AuxNormLocalExtension · minCoord_le`, so q takes values in C `Chapter12/AuxNormLocalExtension · mem_quadrant_boundaryShift`; - the minimum is attained at some i `Chapter12/AuxNormLocalExtension · exists_coord_eq_minCoord`, where the coordinate of q is 0, so q takes values in ∂C `Chapter12/AuxNormLocalExtension · exists_coord_boundaryShift_eq_zero`; - if some $t_i = 0$, the minimum is 0 and q is the identity `Chapter12/AuxNormLocalExtension · boundaryShift_eq_self`.

A point of C has degeneracy index at least 1 iff some half-line coordinate vanishes `Chapter12/AuxNormLocalExtension · one_le_degIndexWith_iff`.

The retraction. By tameness, x_0 lies in a tame chart ψ (`IsTame.exists_chart`) whose model is a tame retract $O = r(U)$, $U \subset C$ relatively open, r a tame sc-smooth retraction. Choose a presentation T of C. *(a) The degeneracy index is read in the chart.* Because r is tame, the degeneracy index of X at $z \in \operatorname{dom}\psi$ equals that of C at $\psi(z)$ (`degIndex_eq_chartDegIndex_of_isTameWith`). So $z \in \partial X$ iff some coordinate t_i of $T\psi(z)$ vanishes. *(b) $n \geq 1$:* $x_0 \in \partial X$ forces a vanishing coordinate. *(c) The domain.* $U = V_0 \cap C$ for an open V_0 of the ambient space; put $V = \operatorname{dom}\psi \cap \psi^{-1}(q^{-1}(V_0))$, open by continuity of ψ and q. It contains x_0: $q(\psi(x_0)) = \psi(x_0) \in O \subset U \subset V_0$ by (a) and the last property of q. *(d) The map.* $\rho = \psi^{-1} \circ r \circ q \circ \psi$ on V. For $y \in V$, $q(\psi(y)) \in V_0 \cap C = U$, so r applies and $r(q(\psi(y))) \in O$, the image of the chart. *(e) Continuity* on V: a composite of continuous maps, r being continuous on level 0 since it is sc-smooth. *(f) Values in ∂X.* Tameness of r means r keeps the degeneracy index: $d_C(r(p)) = d_C(p)$ for $p \in U$ (`degIndex_apply`); $q(\psi(y)) \in \partial C$, so $r(q(\psi(y))) \in \partial C$, and by (a) $\rho(y) \in \partial X$. *(g) The identity on $V \cap \partial X$.* For $y \in V \cap \partial X$, $q(\psi(y)) = \psi(y)$ by (a) and the last property of q; $\psi(y) \in O$ and r is the identity on its image (`apply_eq_self_of_mem_retract`); so $\rho(y) = y$. □

The text takes $x_0 = (0, h_0)$ in the chart. This is not needed: q maps into ∂C and fixes ∂C whatever the coordinates of x_0.

The norm N' (extra, Part I) `Chapter12/AuxNormLocalExtension · StrongBundle.retractNorm`. Fix a strong bun-

dle chart c of the atlas, with base chart φ, model $K = R(U \lhd F)$, and its level-1 form $\Phi[1] : W_{0,1}|\operatorname{dom}\varphi \to (U \lhd F)[1]$. The fibre part of the retraction R of the chart at a base point u is a map $A(u) : F_1 \to F_1$, $h \mapsto \mathrm{pr}_2 R(u,h)$ `Chapter12/AuxNormLocalExtension · StrongBundle.chartFibMap`. Its properties: - $A(u)$ is linear in h `Chapter12/AuxNormLocalExtension · StrongBundle.isLinearMap_chartFibMap`, since R is a strong bundle retraction, linear on fibres; - for $u \in O$, $(u, A(u)h) \in K[1]$ `Chapter12/AuxNormLocalExtension · StrongBundle.mem_K_chartFibMap` and $A(u)h = h$ when $(u,h) \in K[1]$ `Chapter12/AuxNormLocalExtension · StrongBundle.chartFibMap_of_mem`, since R is a retraction onto K; points of O lie in U `Chapter12/AuxNormLocalExtension · StrongBundle.mem_U_of_mem_O`; - $A(u)h$ is the fibre part of the shifted retraction $R[1]$ `Chapter12/AuxNormLocalExtension · StrongBundle.shiftFiber_eq_chartFibMap`, and $(u,h) \mapsto R[1](u,h)$ is continuous on $U \oplus F_1$ `Chapter12/AuxNormLocalExtension · StrongBundle.continuousOn_shiftFiber_R`, as level 0 of the sc-smooth map $R : (U \lhd F)[1] \to (U \lhd F)[1]$.

The chart $\Phi[1]$ reads $W_{0,1}$ over the chart domain: projections commute with it `Chapter12/AuxNormLocalExtension · StrongBundle.proj_oneChartOf_symm` and it agrees with the level-1 lift of the chart `Chapter12/AuxNormLocalExtension · StrongBundle.oneChartOf_toOne`. For a vector w over y with chart coordinates $(u,h) = \Phi[1](w)$ and a map ρ with $\rho(y)$ in the chart domain, the *transport* of w to the fibre over $\rho(y)$ is

$$\Phi[1]^{-1}(\varphi(\rho(y)),\ A(\varphi(\rho(y)))h),$$

a linear map of fibres $W_y \to W_{\rho(y)}$ `Chapter12/AuxNormLocalExtension · StrongBundle.retractTransport`, compatible with the level-1 lift `Chapter12/AuxNormLocalExtension · StrongBundle.liftOneFiber_retractTransport`. Then

$$N'(w) = N(\text{transport of } w) + \|h - A(\varphi(\rho(y)))h\|_{F_1},$$

the text's formula read in $\Phi[1]$ `Chapter12/AuxNormLocalExtension · StrongBundle.retractNorm_toOne`. It is a fibre seminorm over each y in the chart domain with $\rho(y)$ in the chart domain and N a seminorm over $\rho(y)$ `Chapter12/AuxNormLocalExtension · StrongBundle.isFiberSeminorm_retractNorm`: the first term is a seminorm composed with a linear map, the second the norm of a linear expression in h.

N' is a local auxiliary norm `Chapter12/AuxNormLocalExtension · StrongBundle.isLocalAuxNorm_retractNorm`. The lemma is stated for a general set A of base points (not only ∂X), a function N that is continuous on $W_{0,1}|A$, a seminorm on the fibres over A and satisfies condition (2) for sequences over A converging to points of A, and a map ρ continuous on an open V inside the chart domain, with $\rho(V) \subset A \cap \operatorname{dom}\varphi$. Then N' is a local auxiliary norm on V. By §XII.2, three checks.

Write $S = W_{0,1}|V$, $u(w) = \varphi(\rho(P(w)))$, $z(w) = (u(w), A(u(w))\,\mathrm{pr}_2\Phi[1](w)) \in K[1]$ and $T(w) = \Phi[1]^{-1}(z(w))$, which lies over $\rho(P(w))$.

Continuity. $\Phi[1]$ is continuous on S; u is continuous on S (continuity of ρ on V and of φ); z is continuous as $R[1]$ applied to $(u(w), \mathrm{pr}_2\Phi[1](w))$; T is continuous as $\Phi[1]^{-1}$ after z, whose values lie in $K[1]$. Then $N \circ T$ is continuous on S because N is continuous on $W_{0,1}|A$ and $T(w)$ lies over $\rho(P(w)) \in A$; the second term is continuous as a norm of a difference of continuous maps.

Seminorm. Over $y \in V$: the lemma above, with $\rho(y) \in A$.

Condition (2). Let $P(w_k) \to y \in V$ and $N'(w_k) \to 0$. Eventually $w_k \in S$. - Both terms are nonnegative and bounded by $N'(w_k)$, so $N(T(w_k)) \to 0$ and $\|h_k - A(u_k)h_k\| \to 0$, where $h_k = \mathrm{pr}_2\Phi[1](w_k)$, $u_k = u(w_k)$. - $T(w_k)$ lies over $\rho(P(w_k)) \in A$, which converges to $\rho(y) \in A$ by continuity of ρ. Condition (2) for N, applied to the tail of the sequence that lies over V, gives $T(w_k) \to 0_{\rho(y)}$ in $W_{0,1}$. - Reading this in the chart, $\Phi[1](T(w_k)) = z(w_k) \to (\varphi(\rho(y)), 0)$, so $A(u_k)h_k \to 0$ in F_1. - Then

$h_k = (h_k - A(u_k)h_k) + A(u_k)h_k \to 0$ in F_1, and the base coordinates $\varphi(P(w_k)) \to \varphi(y)$. - Convergence in the chart gives convergence in $W_{0,1}$: $w_k \to 0_y$ `Chapter12/AuxNormLocalExtension · MChart.tendsto_of_tendsto_apply`. □

$N' = N$ where ρ is the identity `Chapter12/AuxNormLocalExtension · StrongBundle.retractNorm_eq`: if $y \in V \cap A$ and $\rho(y) = y$, then $N'(w) = N(w)$ for w over y. Indeed $\Phi[1](w) = (\varphi(y), h)$ lies in $K[1]$, so $A(\varphi(y))h = h$; the transport is $\Phi[1]^{-1}(\varphi(y), h) = w$, and the second term is $\|h - h\| = 0$ `Chapter12/AuxNormLocalExtension · StrongBundle.retractNorm_eq_of_fix`.

The local step `Chapter12/AuxNormLocalExtension · StrongBundle.exists_localExtension_of_isTame`. Let X be a tame M-polyfold, and N continuous on $W_{0,1}|\partial X$, a seminorm on the fibres over ∂X, with condition (2) for sequences over ∂X. Every $x_0 \in \partial X$ has an open $V \ni x_0$ and a local auxiliary norm M on V with $M = N$ over $V \cap \partial X$.

Proof. Take ρ and V_1 from the retraction lemma, a strong bundle chart c of the atlas at x_0, and

$$V = V_1 \cap \operatorname{dom}\varphi \cap \rho^{-1}(\operatorname{dom}\varphi),$$

open because ρ is continuous on the open $V_1 \cap \operatorname{dom}\varphi$; it contains x_0 because $\rho(x_0) = x_0$. On V, ρ is continuous with values in $\partial X \cap \operatorname{dom}\varphi$. Put $M = N'$ with $A = \partial X$. By the lemma, M is a local auxiliary norm on V; by the identity clause of the retraction lemma, $\rho(y) = y$ on $V \cap \partial X$, so $M = N$ there. □

For an ep-groupoid, the local step applied to the object M-polyfold, which is tame when X is, discharges the hypothesis of the global part `Chapter12/AuxNormLocalExtension · EpStrongBundle.hasLocalExtensions_of_isTame`: an auxiliary norm over ∂X in the sense above is continuous, a seminorm and satisfies condition (2) over ∂X, which is what the local step asks.

Theorem 12.2.7 is then one line: the global part with the local step `Chapter12/AuxNormLocalExtension · EpStrongBundle.theorem_12_2_7`.

Where the formal proof departs from the text. (a) The text works in a tame local strong bundle model, a strong bundle chart whose base retraction is tame. The formal proof places the retraction onto the boundary in a tame chart of the base, which tameness of X provides, and evaluates the norm formula in an arbitrary strong bundle chart of the atlas. Only the continuity of ρ and its two properties enter the norm formula, so no tame strong bundle chart is needed; the result is the text's statement under the text's hypotheses. (b) The text's formula composes A with $rq(u)$ in the same chart where the fibre lives; the formal N' composes with $\varphi(\rho(y))$, which is the same expression read through ψ and φ. (c) The invariance of N under morphisms is not used in the local step; it enters through Step 4 of the global part, where each term of the average over G_x is identified with N. (d) Tameness is used once, in the retraction lemma, to read the degeneracy index in the chart and to keep it under r.

XII.7 Definition 12.2.8 (2017: 12.5) and Remark 12.2.9 (2017: 12.1): mixed convergence

The second half of §12.2 repeats the first for *reflexive* auxiliary norms, the norms of Part I's Definition 5.1.7 (Part V), which are lower semicontinuous along sequences that converge on the base and weakly on the fibres. They are needed in Chapter 15 for compactness in the presence of perturbations. The

new ingredient is one fact: morphisms preserve mixed convergence (Remark 12.2.9 in the stronger form below). With it, every step of §XII.3 carries lower semicontinuity.

Reflexive 1-fibres (restated) `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.HasReflexiveFibers`, p. 576. The text's standing assumption before Definition 12.2.8 is that the strong bundle has reflexive $(0,1)$-fibres. The formalization reads it on the object bundle in the sense of Part I's Definition 5.1.4: every object lies in the base of a strong bundle chart of the atlas whose fibre F has F_1 reflexive.

Definition 12.2.8 (same) `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.MixedTendsto` `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.definition_12_2_8`, p. 576. A sequence $w_k \in W_{0,1}$ converges *mixed* to $w \in W_{0,1}$ if $P(w_k) \to P(w)$ in X and, in some strong bundle chart around $P(w)$ with reflexive F_1, the fibre coordinates $\mathrm{pr}_2\Phi[1](w_k)$ converge weakly in F_1 to $\mathrm{pr}_2\Phi[1](w)$. It is Part I's mixed convergence on the object bundle; the declaration `definition_12_2_8` records the unfolding.

Remark 12.2.9 (stronger) `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.remark_12_2_9`, pp. 576–577. The text remarks that mixed convergence does not depend on the chart and is compatible with the morphisms. The formal statement has three clauses: for $w_k \to w$ mixed,

- (i) in *every* chart of the atlas around $P(w)$ with reflexive F_1 the fibre coordinates converge weakly;
- (ii) $w_k \to w$ in W (on level 0);
- (iii) for every sc-smooth local section α of the source map on an open $S \ni P(w)$ ($s(\alpha(y)) = y$ for $y \in S$), $\alpha * w_k \to \alpha * w$ mixed `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.mixedTendsto_actOne`.

(i) is Part I's Lemma 5.1.5 (Part V), and (ii) Part I's observation that weak convergence in F_1 implies convergence in F_0 by the compactness of $F_1 \to F_0$. Clause (iii) is the stronger part: the text states compatibility with morphisms; the formal statement gives it along any sc-smooth family of morphisms, which is what the averaging and transport of §XII.3 need. Through a given morphism φ with $s(\varphi) = P(w)$ one takes for α the local inverse of s on the sheet of φ, and gets $\mu(\alpha(P(w_k)), w_k) \to \mu(\varphi, w)$ mixed `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.exists_mixedTendsto_μ`.

Proof of (iii). The text's argument for chart independence uses that a transition map is bounded on the fibres and continuous on level 0. The formal proof applies the same argument to the fibre maps of μ.

Step 1, level 0. The map $w \mapsto \alpha * w$ is sc-smooth on $W|S$ (`isScSmoothOn_sectionAct`), hence continuous on level 0; by (ii), $\alpha * w_k \to \alpha * w$ in W.

Step 2, a bound. Fix a Part I auxiliary norm N_0 of the object bundle. Near any point, two auxiliary norms are comparable: if N, N' are a local auxiliary norm and a continuous fibre seminorm, there are a neighbourhood V and $C > 0$ with $N'(v) \le C\,N(v)$ over V `Chapter12/ReflexiveAuxNormEp · StrongBundle.exists_le_mul_auxNorm`. (This is Part I's Lemma 5.1.2, in local form, proved through the upper and lower bounds of §XII.2.) Applied to N_0 and $N_0 \circ (\alpha*)$, which is a continuous fibre seminorm near $P(w)$: $N_0(\alpha * v) \le C\,N_0(v)$ for $P(v)$ near $P(w)$. A mixed convergent sequence is eventually bounded in N_0 `Chapter12/ReflexiveAuxNormEp · StrongBundle.MixedTendsto.exists_eventually_le`: its fibre coordinates converge weakly, hence are bounded in F_1 by the uniform boundedness principle, and N_0 is bounded by a multiple of the chart norm near $P(w)$. So $N_0(\alpha * w_k)$ is eventually bounded.

Step 3, bounded and convergent on level 0 *implies mixed* `Chapter12/ReflexiveAuxNormEp · StrongBundle.mixedTendsto_of_bounded`. Let $v_k \to v$ in W with $N_0(v_k) \le r$ eventually. Take a chart around $P(v)$ with reflexive F_1 (reflexive fibres). Near $P(v)$, N_0 dominates a multiple of the chart norm (the lower bound of §XII.2, ex–

ists_bounds), so the fibre coordinates are eventually bounded in F_1. A bounded sequence in a reflexive space whose limit on level 0 is known converges weakly to that limit (weakTendsto_liftOneSnd_of_tendsto, Part I): every subsequence has a weakly convergent subsequence (weak sequential compactness in reflexive spaces, Part V), its weak limit equals the level-0 limit because $F_1 \to F_0$ is continuous and limits in F_0 are unique, so all subsequential weak limits agree, and the whole sequence converges weakly. Hence $v_k \to v$ mixed.

Steps 1–3 give (iii). □

Lower semicontinuity along mixed convergence (extra) Chapter12/ReflexiveAuxNormEp · StrongBundle.MixedLscAt. A function M on $W_{0,1}$ is *mixed lower semicontinuous at* w if for every sequence $w_k \to w$ mixed and every $\varepsilon > 0$, eventually $M(w) - \varepsilon < M(w_k)$. This implies $M(w) \le \liminf_k M(w_k)$ in the extended reals Chapter12/ReflexiveAuxNormEp · StrongBundle.MixedLscAt.le_liminf, the form in Definition 12.2.10. The pointwise ε-form is used because it composes well:

- *sums*: if M_1, M_2 are mixed lower semicontinuous at w, so is $M_1 + M_2$, with $\varepsilon/2$ for each Chapter12/ReflexiveAuxNormEp · StrongBundle.MixedLscAt.add, and so are finite sums Chapter12/ReflexiveAuxNormEp · StrongBundle.mixedLscAt_finset_sum;
- *nonnegative constants*: cM for $c \ge 0$, with ε/c (trivially for $c = 0$) Chapter12/ReflexiveAuxNormEp · StrongBundle.MixedLscAt.const_mul;
- *products with functions of the base point* Chapter12/ReflexiveAuxNormEp · StrongBundle.MixedLscAt.mul_comp: if $g \ge 0$ is continuous at $P(w)$ and $M \ge 0$ over an open $V \ni P(w)$, then $w \mapsto g(P(w))M(w)$ is mixed lower semicontinuous at w. With $a = g(P(w))$, $b = M(w)$ and $\delta = \varepsilon/(a + b + 1)$: eventually $g(P(w_k)) > a - \delta$ (continuity of g along $P(w_k) \to P(w)$), $M(w_k) > b - \delta$, and both are nonnegative; then $g(P(w_k))M(w_k) \ge ab - \delta(a + b) > ab - \varepsilon$;
- *functions that vanish at the point* Chapter12/ReflexiveAuxNormEp · StrongBundle.mixedLscAt_of_nonpos: if $M(w) \le 0$ and $M \ge 0$ everywhere, M is mixed lower semicontinuous at w;
- *local agreement* Chapter12/ReflexiveAuxNormEp · StrongBundle.MixedLscAt.congr: if $M = M'$ over an open $V \ni P(w)$, the property passes, because $P(w_k) \in V$ eventually;
- *constants* Chapter12/ReflexiveAuxNormEp · StrongBundle.mixedLscAt_const;
- *through morphisms* Chapter12/ReflexiveAuxNormEp · EpStrongBundle.mixedLscAt_comp_actOne: if M is mixed lower semicontinuous at $\alpha * w$, then $M \circ (\alpha*)$ is at w, by (iii) of Remark 12.2.9.

XII.8 Definition 12.2.10, Theorem 12.2.11 and Remark 12.2.12 (2017: Definition 12.6, Theorem 12.4, Remark 12.2): reflexive auxiliary norms exist

Definition 12.2.10 (same) Chapter12/ReflexiveAuxNormEp · EpStrongBundle.IsReflexiveAuxNorm, p. 577. A reflexive auxiliary norm is an auxiliary norm N (Definition 12.2.1: continuous, invariant under morphisms, a complete norm on each fibre, condition (2)) with the additional property (3): $N(w) \le \liminf_k N(w_k)$ whenever $w_k \to w$ mixed, the liminf taken in the extended reals. The text prints the liminf as $k \to 0$; it is presumably $k \to \infty$, as in Part I's Definition 5.1.7 (Part V), and is read so. A reflexive auxiliary norm of the ep-groupoid is one of Part I's on the object bundle Chapter12/ReflexiveAuxNormEp · EpStrongBundle.IsReflexiveAuxNorm.toStrong, and it is mixed lower semicontinuous at every point Chapter12/ReflexiveAuxNormEp · StrongBundle.IsReflexiveAuxNorm.mixedLscAt Chapter12/ReflexiveAuxNormEp · EpStrongBundle.IsReflexiveAuxNorm.mixedLscAt (the liminf inequality gives the ε-form).

Conversely, an auxiliary norm that is mixed lower semicontinuous at every point is reflexive Chapter12/ReflexiveAuxNormEp · EpStrongBundle.isReflexiveAuxNorm_of_mixedLscAt. The constructions below prove the ε-form and convert at the end.

Theorem 12.2.11 (same) Chapter12/ReflexiveAuxNormEp · EpStrongBundle.theorem_12_2_11, p. 577. Let $(P : W \to X, \mu)$ be a strong bundle over an ep-groupoid with paracompact $|X|$ and reflexive $(0,1)$-fibres. Then (1) reflexive auxiliary norms exist; (2) if N is one and $f : X \to (0,\infty)$ is continuous and constant along morphisms, then $h \mapsto f(P(h))N(h)$ is one; (3) for every auxiliary norm N' there are reflexive auxiliary norms $N_1 \le N' \le N_2$. The hypotheses are the text's; the formal statement is the conjunction of the three clauses.

(1) Existence Chapter12/ReflexiveAuxNormEp · EpStrongBundle.theorem_12_2_11_exists. The construction is that of Theorem 12.2.2 (§XII.3), with lower semicontinuity carried through each step.

The local norms. The text takes on $U(x)$ the norm $\|\mathrm{pr}_2 \circ \Psi(g * h)\|_{F_1}$ in a chart with reflexive F_1. The formal proof takes the restriction of one reflexive auxiliary norm N_0 of the object bundle, which Part I's Proposition 5.1.8 (Part V) provides under reflexive fibres; it is mixed lower semicontinuous everywhere.

Average Chapter12/ReflexiveAuxNormEp · EpStrongBundle.mixedLscAt_avgNorm. Each term $M(g * w)$ of $\bar{M}(w) = |G_x|^{-1} \sum_g M(g * w)$ is mixed lower semicontinuous at w over $U(x)$: $g*$ is the action of the sc-smooth family of morphisms $\Gamma(g, \cdot)$, so the property passes through it; the finite sum and the factor $|G_x|^{-1}$ keep it.

Transport Chapter12/ReflexiveAuxNormEp · EpStrongBundle.mixedLscAt_transNorm. Near a point w_0 over the saturation, §XII.3 showed $T = \bar{M} \circ (\rho*)$ for a local inverse ρ of s; this is an sc-smooth local section of s, so the property passes through $\rho*$, and T agrees with $\bar{M} \circ (\rho*)$ on a neighbourhood, so it passes to T by local agreement.

Glue Chapter12/ReflexiveAuxNormEp · EpStrongBundle.mixedLscAt_glueNorm. Fix w over y. By local finiteness, $\pi(y)$ has a neighbourhood n in $|X|$ meeting only finitely many supports; on $O = \pi^{-1}(\mathrm{int}\, n)$, open and containing y, $\tilde{N} = \sum_{i \in F} (\beta_i \circ \pi \circ P) T_i$ for a finite set F. For $i \in F$: - if $y \in S_i$ (the saturation carrying T_i): T_i is mixed lower semicontinuous at w and nonnegative over the open S_i, and $\beta_i \circ \pi$ is continuous and nonnegative, so the product rule applies; - if $y \notin S_i$: then $\beta_i(\pi(y)) = 0$, since $\mathrm{supp}\, \beta_i \subset \pi(S_i)$; the term vanishes at w and is nonnegative, so it is mixed lower semicontinuous at w.

The finite sum is mixed lower semicontinuous, and so is $\tilde{N}$ by local agreement on O. The text's argument for (3) at this point is "since the sum is locally finite"; the formal proof shows that this suffices, the terms with vanishing coefficient at the limit being harmless because they are nonnegative.

Conclusion Chapter12/ReflexiveAuxNormEp · EpStrongBundle.isReflexiveAuxNorm_glueNorm: $\tilde{N}$ is an auxiliary norm by §XII.3 and mixed lower semicontinuous everywhere, hence reflexive.

(2) Scaling Chapter12/ReflexiveAuxNormEp · EpStrongBundle.theorem_12_2_11_mul, which is **Remark 12.2.12 (1)** (same) Chapter12/ReflexiveAuxNormEp · EpStrongBundle.remark_12_2_12_1, p. 577. Let N be a reflexive auxiliary norm and $f > 0$ continuous with $f(s(\varphi)) = f(t(\varphi))$. Then $(f \circ P)N$ is: continuous as a product; a complete norm on each fibre, being a positive multiple of one; condition (2): if $P(h_k) \to x$ and $f(P(h_k))N(h_k) \to 0$, then $N(h_k) \to 0$ because $f(P(h_k)) \to f(x) > 0$; invariant because f is constant along morphisms and N invariant; and mixed lower semicontinuous by the product rule.

Remark 12.2.12 (2) (same) Chapter12/ReflexiveAuxNormEp · EpStrongBundle.remark_12_2_12_2, p. 577. For auxiliary norms N_1, N_2 and paracompact $|X|$ (which the remark's context has), there is a continuous

$f : X \to (0,\infty)$, constant along morphisms, with $N_1 \le (f \circ P)N_2$.

Step 1, local constants. For every object y, the local comparison lemma of §XII.7 gives an open $V_y \ni y$ and $C_y > 0$ with $N_1(w) \le C_y N_2(w)$ over V_y.

Step 2, saturation. The bound holds over $\mathrm{sat}(V_y)$: for w over z with a morphism $\varphi : z \to z'$, $z' \in V_y$, the vector $k = \mu(\varphi, w)$ `Chapter8/Book2021 · EpStrongBundle.exists_oneVal_eq_μ` lies over V_y, and $N_i(w) = N_i(k)$ by invariance of both norms.

Step 3, glue the constants. Let (β_y) be a partition of unity of $|X|$ subordinate to the open cover $(\pi(\mathrm{sat}(V_y)))_y$, and $g = \sum_y \beta_y C_y$ on $|X|$, continuous by local finiteness and positive because at each point some $\beta_y > 0$. Put $f = g \circ \pi$, continuous and constant along morphisms.

Step 4, the estimate. For w over z with $\pi(z) = \zeta$:

$$N_1(w) = \sum_y \beta_y(\zeta) N_1(w) \le \sum_y \beta_y(\zeta) C_y N_2(w) = f(z) N_2(w),$$

the inequality termwise: where $\beta_y(\zeta) \neq 0$, $z \in \mathrm{sat}(V_y)$ by subordination and Step 2 applies. □

Remark 12.2.12 (3) (stronger) `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.remark_12_2_12_3`, p. 578. The text: for a saturated open U, a function $N \ge 0$ on $W_{0,1}|U$ satisfying the liminf inequality there, and a continuous functorial $f \ge 0$ with support in U, the function $\tilde{N} = f \cdot N$ on U, 0 off U, satisfies the liminf inequality on all of $W_{0,1}$. The formal statement drops what the estimate does not use: U open (not necessarily saturated), $N \ge 0$ and mixed lower semicontinuous over U, $f \ge 0$ continuous (not necessarily functorial or supported in U). *Proof.* Fix $w_k \to w$ mixed. If $P(w) \in U$: the product rule gives lower semicontinuity of $(f \circ P)N$ at w, and $\tilde{N}$ agrees with it over the open U, so local agreement applies. If $P(w) \notin U$: $\tilde{N}(w) = 0$ and $\tilde{N} \ge 0$ everywhere. In both cases the liminf inequality follows. □ The saturation of U, the functoriality of f and $\mathrm{supp}\, f \subset U$ serve the continuity and the invariance of $\tilde{N}$, which the text uses when it applies the remark, not the estimate.

(3) The sandwich `Chapter12/ReflexiveAuxNormEp · EpStrongBundle.theorem_12_2_11_sandwich`. Given an auxiliary norm N', take a reflexive N from (1). Remark 12.2.12 (2), applied twice, gives functorial continuous $f, g > 0$ with $N \le (f \circ P)N'$ and $N' \le (g \circ P)N$. Put $N_1 = (f \circ P)^{-1}N$ and $N_2 = (g \circ P)N$; both are reflexive by (2) (with $1/f$ and g), and $N_1 \le N' \le N_2$. □

XII.9 Theorem 12.2.13 (2017: 12.5): extension of reflexive auxiliary norms

Theorem 12.2.13 (explicit) `Chapter12/ReflexiveLocalExtension · EpStrongBundle.theorem_12_2_13`, p. 578. Let X be a tame ep-groupoid with $|X|$ paracompact, $(P : W \to X, \mu)$ a strong bundle with reflexive $(0,1)$-fibres, and N a reflexive auxiliary norm of $W_{0,1}|\partial X$. Then there is a reflexive auxiliary norm $\tilde{N}$ of W with $\tilde{N} = N$ over ∂X.

Explicit: the paracompactness of $|X|$ is not printed in the statement. The proof refers to "partitions of unity, as in Theorem 12.2.11", which takes it from Theorem 12.2.11; Theorem 12.2.7, whose construction is reused, states it. *A reading*: a reflexive auxiliary norm "for $W_{0,1}|\partial X$" asks the liminf inequality only for mixed convergent sequences over ∂X. The proof needs no more, because the first term of the local norm N' is evaluated over $\rho(\cdot) \in \partial X$.

The proof has the two parts of §XII.6, each with lower semicontinuity added.

Reflexive norms over a subset `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.IsReflexiveAuxNormOn`: an auxiliary norm over A (§XII.6) with $N(w) \le \liminf N(w_k)$ for mixed convergent sequences over A with limit over A. A global reflexive norm restricts `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.IsReflexiveAuxNorm.isReflexiveAuxNormOn`.

The global part

Reflexive local extensions `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.HasReflexiveLocalExtensions`: every $x \in \partial X$ has an open $V \ni x$ and a local auxiliary norm M on V, mixed lower semicontinuous at every vector over V, with $M = N$ over $V \cap \partial X$. They are in particular local extensions in the sense of §XII.6 `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.HasReflexiveLocalExtensions.hasLocalExtensions`.

The global part `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.theorem_12_2_13_hyp`: for paracompact $|X|$, reflexive $(0,1)$-fibres and a reflexive auxiliary norm N over ∂X with reflexive local extensions, there is a reflexive auxiliary norm $\tilde{N}$ of W with $\tilde{N} = N$ over ∂X. *Proof.* Steps 1–4 of §XII.6, with these choices: at boundary points the reflexive local extensions; at interior points the restriction of a reflexive auxiliary norm N_0 of the object bundle (Part I's Proposition 5.1.8). The result is an auxiliary norm equal to N over ∂X by §XII.6. Its lower semicontinuity: the averages, transports and the glued sum keep mixed lower semicontinuity by the three lemmas of §XII.8 (`mixedLscAt_avgNorm`, `mixedLscAt_transNorm`, `mixedLscAt_glueNorm`), which hold for any local norms that are mixed lower semicontinuous. So $\tilde{N}$ is reflexive. □

A property of this Lean statement. The global part takes the reflexive local extensions as a hypothesis; it is valid as stated and serves as the global half of Theorem 12.2.13, the hypothesis being discharged below for every tame X. Its satisfiability witnesses: the restriction of a global reflexive norm has reflexive local extensions `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.hasReflexiveLocalExtensions_of_isReflexiveAuxNorm`, so every bundle with reflexive fibres and paracompact $|X|$ satisfies all hypotheses of the global part `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.theorem_12_2_13_hyp_witness`; concretely the trivial bundle $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ over the trivial ep-groupoid of $\mathbb{R}^n$ `Chapter12/ReflexiveAuxNormExtension · TrivialBundle.epBundle_reflexive_witness`. These are consistency checks: in the first the extension is the global norm itself, and in the second $\mathbb{R}^n$ is modelled on all of $\mathbb{R}^n$ with a single chart, so $\partial X = \emptyset$ and the boundary condition is empty.

The local step: the inspection

The text says that the local extension N' of Theorem 12.2.7 is well behaved under mixed convergence "by inspection". The formal proof supplies the inspection, in three lemmas.

The setting. Near $x_0 \in \partial X$, in a tame chart of the base with the retraction ρ onto ∂X (§XII.6), and in a strong bundle chart Φ with fibre F, F_1 reflexive (which reflexive fibres provide around every point), write $u(w) = \varphi(\rho(P(w)))$ and $A(u)$ for the fibre map of the retraction of the chart; then

$$N'(w) = N\big(\Phi[1]^{-1}(u, A(u)h)\big) + \|h - A(u)h\|_{F_1},$$

where h is the fibre coordinate of w.

Two facts about the fibre maps.

A uniform bound Chapter12/ReflexiveLocalExtension · StrongBundle.exists_norm_chartFibMap_le: near a point u_0 of the chart domain, $\|A(u)\|_{L(F_1)} \le C$ uniformly in u. *Proof.* $(u,h) \mapsto A(u)h$ is continuous at $(u_0,0)$ on level 1 (§XII.6), so for u near u_0 and $\|h\| \le \delta$, $\|A(u)h\| \le 1$; by linearity $\|A(u)\| \le 1/\delta$.

Weak convergence Chapter12/ReflexiveLocalExtension · StrongBundle.weakTendsto_chartFibMap: if $u_k \to u$ and $h_k \rightharpoonup h$ in the reflexive F_1, then $A(u_k)h_k \rightharpoonup A(u)h$. *Proof.* (a) h_k is bounded (uniform boundedness), so $A(u_k)h_k$ is bounded by the uniform bound. (b) The inclusion $F_1 \to F_0$ is compact, so $h_k \to h$ in F_0; the retraction is continuous on level 0, so $A(u_k)h_k \to A(u)h$ in F_0. (c) A bounded sequence in the reflexive F_1 that converges in F_0 converges weakly in F_1 to the same limit, as in Step 3 of Remark 12.2.9. The fibre map lies over the base point Chapter12/ReflexiveLocalExtension · StrongBundle.toBase_chartFibMap, and weak limits are compatible with differences Chapter12/ReflexiveLocalExtension · WeakTendsto.sub.

The inspection Chapter12/ReflexiveLocalExtension · StrongBundle.mixedLscAt_retractNorm: let N be mixed lower semicontinuous at the vectors over a set A containing $\rho(V)$; then N' is mixed lower semicontinuous at every w with $P(w) \in V$. *Proof.* Let $w_k \to w$ mixed, and read in the chart with reflexive F_1: $u_k = u(w_k) \to u(w)$ by continuity of ρ, and $h_k \rightharpoonup h$ in F_1 (Remark 12.2.9 (i), for this chart). - *Second term.* By the weak convergence fact, $h_k - A(u_k)h_k \rightharpoonup h - A(u)h$; the norm of a Banach space is weakly lower semicontinuous, so $\|h - A(u)h\| \le \liminf \|h_k - A(u_k)h_k\|$. - *First term.* The vectors $T(w_k) = \Phi[1]^{-1}(u_k, A(u_k)h_k)$ lie over $\rho(P(w_k)) \in A$; their base points converge to $\rho(P(w))$ and their fibre coordinates converge weakly in F_1 by the same fact. So $T(w_k) \to T(w)$ mixed (Definition 12.2.8 in this chart), and $N(T(w)) \le \liminf N(T(w_k))$ by the hypothesis on N. - The ε-form for the sum follows from those of the two terms.

The set A is a parameter, so the lemma serves any extension step from a closed subset with a continuous retraction, not only $A = \partial X$. □

The local step Chapter12/ReflexiveLocalExtension · StrongBundle.exists_reflexiveLocalExtension_of_isTame: on a tame M-polyfold with a strong bundle with reflexive $(0,1)$-fibres, a function N that is continuous over ∂X, a fibre seminorm over ∂X, satisfies condition (2) for sequences over ∂X and is mixed lower semicontinuous at vectors over ∂X for sequences over ∂X has, at every $x_0 \in \partial X$, a local auxiliary norm M on an open $V \ni x_0$, mixed lower semicontinuous at every vector over V, with $M = N$ over $V \cap \partial X$. *Proof.* Choose the strong bundle chart of §XII.6 among those with reflexive F_1. Then $M = N'$; that it is a local auxiliary norm equal to N on the boundary is §XII.6, and its lower semicontinuity is the inspection with $A = \partial X$; the mixed convergent sequences that the inspection feeds to N lie over $\rho(V) \subset \partial X$, so the hypothesis on N over ∂X suffices. □ Tameness enters only through the retraction onto the boundary.

On the ep-groupoid, the local step in the object M-polyfold discharges the hypothesis of the global part for every tame X Chapter12/ReflexiveLocalExtension · EpStrongBundle.hasReflexiveLocalExtensions_of_isTame, and Theorem 12.2.13 is the global part with this hypothesis discharged.

Witness. The hypotheses together are satisfiable Chapter12/ReflexiveLocalExtension · TrivialBundle.theorem_12_2_13_witness: the trivial bundle $\mathbb{R}^n \times \mathbb{R}^k$ over the tame trivial ep-groupoid of $\mathbb{R}^n$, with a reflexive auxiliary norm over its boundary. This witness is degenerate: the M-polyfold $\mathbb{R}^n$ of the project (`rnPolyfold`) has the single chart onto all of $\mathbb{R}^n$, so $\partial X = \emptyset$ and the boundary data are vacuous. Since Theorem 12.2.13 adds no hypothesis beyond the text's (paracompactness of $|X|$ being explicit), the witness checks only that the hypotheses are consistent; a non-degenerate case would take a tame ep-groupoid with boundary, such as the quadrant witness of Proposition 12.3.7 (§XII.12) seen as a trivial ep-groupoid, and a reflexive norm over its boundary, restricted from a global one by Theorem 12.2.11.

XII.10 Definition 12.3.1 (2017: 12.7) and Theorem 12.3.2 (2017: 12.6): bump functions

§12.3 supplies sc⁺-section functors, the perturbations of the later chapters. A section functor must commute with the morphisms; the sc⁺-sections of Part I, built with bump functions in charts, do not. The remedy is the pattern of §12.2 once more: bump functions and sections are built near a point with the natural action, averaged over the isotropy group and extended to the saturation by the morphisms.

Definition 12.3.1, as printed (same) `Chapter12/BumpEp · EpGroupoid.AdmitsBumpFunctions`, p. 579. An ep-groupoid X admits sc-smooth bump functions if for every object x and every saturated open $U \ni x$ there is an sc-smooth $f : X \to \mathbb{R}$ on the object M-polyfold, not identically 0, with $\operatorname{supp} f \subset U$ and $f(s(\varphi)) = f(t(\varphi))$ for every morphism φ.

The pointwise reading `Chapter12/BumpEp · EpGroupoid.AdmitsBumpFunctionsPointwise` asks $f(x) \neq 0$ instead of $f \neq 0$. It is the project's reading of Part I's Definition 5.3.1 (Part V), where the bump function at x is read as nonzero at x. The pointwise reading implies the printed one `Chapter12/BumpEp · EpGroupoid.AdmitsBumpFunctionsPointwise.weak`. The two readings are kept side by side because Part I has a matching pair: `MPolyfold.AdmitsBumpFunctions` (pointwise) and `MPolyfold.AdmitsBumpFunctionsWeak` (not identically zero), and whether the second implies the first is Part I's open weak-to-pointwise question (Part V).

Tools on saturations. The saturation of an open set is open `Chapter12/BumpEp · EpGroupoid.isOpen_saturation_of_isOpen`, because $\operatorname{sat}(V) = t(s^{-1}(V))$ and t is a local homeomorphism, hence open. The saturation is saturated `Chapter12/BumpEp · EpGroupoid.isSaturated_saturation`, and is contained in any saturated set containing V `Chapter12/BumpEp · EpGroupoid.saturation_subset_of_isSaturated`. Two objects with the same orbit are joined by a morphism `Chapter12/BumpEp · EpGroupoid.eq_of_π_eq`. Around every x in an open U there are a natural representation R of G_x with $R.U \subset U$ and an open $V \ni x$ invariant under R with $\overline{V} \subset R.U$ and $\overline{V}$ proper (Chapter 7, `exists_invariant_nhds_of_isOpen`); "proper" is Chapter 7's notion: the restriction of t to $s^{-1}(\overline{V})$ is proper, so the saturation of a closed subset of $\overline{V}$ is closed `Chapter7/ProperSubsets · isClosed_saturation_of_isProperSubset`.

Averaging a function `Chapter12/BumpEp · EpGroupoid.exists_natAverage`. Let R be a natural representation on $U(x)$, V invariant with $\overline{V} \subset U(x)$, and g sc-smooth with $\operatorname{supp} g \subset V$. Then there is an sc-smooth h with $\operatorname{supp} h \subset V$, invariant under $\Phi(k)$ on $U(x)$, and equal to $|G_x|^{-1} \sum_k g(\Phi(k)y)$ on $U(x)$. *Proof.* Each $g_k = \mathbf{1}_{U(x)} \cdot (g \circ \Phi(k))$ is sc-smooth: on $U(x)$ it is $g \circ \Phi(k)$, with $\Phi(k)$ an sc-diffeomorphism of $U(x)$; near a point $y \notin U(x)$ it vanishes, because $\operatorname{supp}(g \circ \Phi(k)) \subset \Phi(k)^{-1}(\overline{V}) = \overline{V}$ by invariance, a closed set inside $U(x)$, so a neighbourhood of y misses it. The average of the g_k is h; its support lies in V by invariance of V; it is Φ-invariant by reindexing.

Extending an invariant function `Chapter12/BumpEp · EpGroupoid.exists_invariant_extension`. With $\overline{V}$ proper in addition, an sc-smooth h supported in V and invariant under Φ on $U(x)$ extends to an sc-smooth β on X, constant along morphisms, equal to h on $U(x)$, with support in $\operatorname{sat}(\overline{V})$ and values in $h(U(x)) \cup \{0\}$. *Proof.* $\beta = \bar{h} \circ \pi$, where $\bar{h}$ on $|X|$ is h on $\pi(U(x))$ and 0 elsewhere (Chapter 7's `orbitExtension`); it is well defined because h is invariant under all morphisms between points of $U(x)$, which are the $\Gamma(k, \cdot)$. It is sc-smooth (`isScSmoothMap_orbitExtension`): on the saturation of $U(x)$, near y with a morphism $\varphi : y \to y'$, $\beta = h \circ t \circ \sigma$ for a local inverse σ of s at φ; off $\operatorname{sat}(\operatorname{supp} h)$, which is closed because $\operatorname{supp} h \subset \overline{V}$ is proper, β vanishes on a neighbourhood. The support is the closure of $\operatorname{sat}(\{h \neq 0\})$, inside the closed $\operatorname{sat}(\overline{V})$.

Theorem 12.3.2 (1) (restated), p. 579: X admits sc-smooth bump functions iff the object M-polyfold does. It is proved in each consistent reading: pointwise on both sides `Chapter12/BumpEp · EpGroupoid.theorem_12_3_2_1` and "not identically 0" on both sides `Chapter12/BumpEp · EpGroupoid.theorem_12_3_2_1_weak`. The printed statement pairs Definition 12.3.1 ("not identically 0") with Part I's Definition 5.3.1, which this project reads pointwise; its direction (□) would then be Part I's weak-to-pointwise question, which is open. This is a reading of the statement, recorded as such, not a gap in the formalization.

(□), from ep bump functions to object bump functions `Chapter12/BumpEp · EpGroupoid.exists_objBump_of_epBump`. Let $x \in U$, U open (not necessarily saturated). *Step 1.* Choose R and V as above, with $\overline{V} \subset R.U \subset U$. *Step 2.* Apply the hypothesis to the saturated open set $\mathrm{sat}(V) \ni x$: an invariant sc-smooth f with $\mathrm{supp}\, f \subset \mathrm{sat}(V)$, nonzero at x (pointwise reading) or not identically zero. *Step 3, the cut-off* $\mathbf{1}_V f$. It equals f on V and has support in $\overline{V} \subset U$. It is sc-smooth: on the open V it is f; near a point outside $\overline{V}$ it is 0; at a point $y \in \overline{V} \setminus V$, $y \notin \mathrm{supp}\, f$, because a point of $\mathrm{supp}\, f \subset \mathrm{sat}(V)$ that lies in $\overline{V} \subset R.U$ is joined by a morphism to a point of V, hence is $\Phi(k)$ of a point of V (Theorem 7.1.13), hence lies in V by invariance; so f vanishes near y, and so does $\mathbf{1}_V f$. *Step 4, nonvanishing.* Pointwise: $(\mathbf{1}_V f)(x) = f(x) \neq 0$. Weak: if $f(z) \neq 0$, then $z \in \mathrm{sat}(V)$, so z is joined to some $y \in V$ and $f(y) = f(z) \neq 0$ by invariance of f.

(□), from object bump functions to ep bump functions `Chapter12/BumpEp · EpGroupoid.exists_epBump_of_objBump`. Let $x \in U$, U saturated and open. *Step 1.* R and V as above. *Step 2.* An object bump function g at x with support in V. *Step 3, average the square.* Average g^2 over G_x (the averaging lemma) and extend (the extension lemma) to an invariant sc-smooth β with support in $\mathrm{sat}(\overline{V}) \subset U$ (the last because U is saturated and contains $\overline{V}$), and with $\beta \geq |G_x|^{-1} g^2$ on $R.U$: the average of the nonnegative $g^2 \circ \Phi(k)$ is at least its $k = 1$ term divided by $|G_x|$. *Step 4, nonvanishing.* Pointwise: $\beta(x) \geq |G_x|^{-1} g(x)^2 > 0$. Weak: if $g(y) \neq 0$ then $y \in V \subset R.U$ and $\beta(y) > 0$.

Where the formal proof departs from the text. The text averages f itself. The average of a function over a finite group can vanish identically even if the function does not (for example g and $g \circ \Phi(k) = -g$). The formal proof averages g^2, which is presumably what is intended, since the bump functions of Part I's Proposition 5.5.3 are nonnegative, and with nonnegative g the text's average is already fine.

Theorem 12.3.2 (2) (narrower) `Chapter12/BumpEp · EpGroupoid.theorem_12_3_2_2`, p. 579. If X admits sc-smooth bump functions in the pointwise reading, then for every x and saturated open $U \ni x$ there is an sc-smooth $f : X \to [0,1]$, constant along morphisms, with $f(x) = 1$ and $\mathrm{supp}\, f \subset U$.

Proof, the text's. *Step 1.* R and V as above. *Step 2.* By (1), the object M-polyfold admits bump functions, and Part I's Proposition 5.5.3 `Chapter5/BumpFunctions · proposition_5_5_3` gives $g : X \to [0,1]$, sc-smooth, with $g \equiv 1$ near x and $\mathrm{supp}\, g \subset V$. *Step 3.* Average g (not its square: $g \geq 0$ here) to h and extend h to f. *Step 4, the values.* On $R.U$, $f = h = |G_x|^{-1} \sum_k g \circ \Phi(k)$ lies in $[0,1]$, as an average of numbers in $[0,1]$; elsewhere f takes values in $h(R.U) \cup \{0\} \subset [0,1]$. At x, $\Phi(k)(x) = x$ for every k, so $f(x) = |G_x|^{-1} \cdot |G_x| \cdot 1 = 1$. □

Narrower only by the pointwise reading of the hypothesis. Witnesses of the pointwise reading: the trivial ep-groupoid on $\mathbb{R}^n$ `Chapter12/BumpEp · EpGroupoid.admitsBumpFunctionsPointwise_trivial_rn`, and in general every ep-groupoid whose object M-polyfold admits bump functions `Chapter12/BumpEp · EpGroupoid.admitsBumpFunctionsPointwise_of_objects`, which is (1) read backwards.

XII.11 Theorem 12.3.3 (2017: 12.7), Remarks 12.3.4 and 12.3.5 (2017: 12.3, 12.4): sc⁺-section functors through a point

The text proves Theorem 12.3.3 with a construction that it states afterwards, in Remark 12.3.5. This section gives the tools first, then the theorem, then the two remarks in the book's order; the proof of the theorem cites the remark's construction.

Morphisms acting on sections. For a section σ of the object bundle and a morphism φ, put $\varphi \cdot \sigma = \mu(\varphi, \sigma(s(\varphi)))$, a vector over $t(\varphi)$ `Chapter12/ScPlusSectionFunctor · EpStrongBundle.secAct`. It respects composition, $(\psi \circ \varphi)\cdot\sigma = \mu(\psi, \varphi\cdot\sigma)$ `Chapter12/ScPlusSectionFunctor · EpStrongBundle.secAct_comp`, and units, $1_x \cdot \sigma = \sigma(x)$ `Chapter12/ScPlusSectionFunctor · EpStrongBundle.secAct_unit`; a section is functorial iff $\varphi\cdot\sigma = \sigma(t(\varphi))$ for all φ `Chapter12/ScPlusSectionFunctor · EpStrongBundle.secAct_eq_of_isFunctorialSection`.

Smoothness along a family of morphisms `Chapter12/ScPlusSectionFunctor · EpStrongBundle.exists_isScSmoothOn_one_secAct`. If σ is an sc⁺-section and τ is an sc-smooth family of morphisms on an open set (for instance the local inverse of t on a sheet), then $y \mapsto \mu(\tau(y), \sigma(s(\tau(y))))$ is sc-smooth into $W[1]$ there. *Proof.* An sc⁺-section is an sc-smooth map into $W[1]$ `Chapter12/ScPlusSectionFunctor · StrongBundle.IsScPlusSection.exists_one`. The map $y \mapsto (\tau(y), \sigma(s(\tau(y))))$ into the pull-back $\mathbf{X}_s \times_P W[1]$ is sc-smooth by the universal property of the pull-back at level $[1]$ (`isScSmoothOn_to_pullback_one`), and μ is a strong bundle map, so sc-smooth from the pull-back of $W[1]$ to $W[1]$ (`isStrongBundleMap.isScSmoothMap_one`). *Locality* `Chapter12/ScPlusSectionFunctor · StrongBundle.isScPlusSection_of_locally`: a section that agrees near every point with an sc-smooth map into $W[1]$ is an sc⁺-section.

Sums and bounds. Sums of sections are taken fibrewise; at the base point of $\mu(\varphi, \cdot)$ the sum is carried termwise `Chapter12/ScPlusSectionFunctor · EpStrongBundle.sectionSum_tgt`, and a complete fibre norm is subadditive on finite sums `Chapter12/ScPlusSectionFunctor · StrongBundle.IsCompleteFiberNorm.sum_le`. A section σ satisfies the *bound* b for N if $N(\sigma(y)) \le b$ wherever $\sigma(y) \in W_{0,1}$ `Chapter12/ScPlusSectionFunctor · EpStrongBundle.NormBound`; for an auxiliary norm, $N(\varphi\cdot\sigma) = N(\sigma(s(\varphi)))$ `Chapter12/ScPlusSectionFunctor · EpStrongBundle.IsAuxNorm.secAct_eq`, by invariance.

The equivariant average `Chapter12/ScPlusSectionFunctor · EpStrongBundle.exists_equivariant_average`. Let R be a natural representation on $U(x)$, V invariant with $\overline{V} \subset U(x)$, and s an sc⁺-section with support in V. For $k \in G_x$ define

$$h_k(y) = \mu(\Gamma(k, \Phi(k^{-1})y),\ s(\Phi(k^{-1})y)) \text{ for } y \in U(x), \qquad h_k(y) = 0 \text{ otherwise}$$

`Chapter12/ScPlusSectionFunctor · EpStrongBundle.natTerm`, the translate of s by k. Each h_k is an sc⁺-section `Chapter12/ScPlusSectionFunctor · EpStrongBundle.isScPlusSection_natTerm`: on $U(x)$ by the smoothness lemma along the sc-smooth family $y \mapsto \Gamma(k, \Phi(k^{-1})y)$, and near points outside $U(x)$ it vanishes, since its support lies in $\Phi(k)(\overline{V}) = \overline{V}$. The translates are permuted by morphisms `Chapter12/ScPlusSectionFunctor · EpStrongBundle.natTerm_tgt`: for a morphism $\psi = \Gamma(\gamma, y)$ between points of $U(x)$, $h_{\gamma k}(t(\psi)) = \mu(\psi, h_k(s(\psi)))$, by the composition law $\Gamma(\gamma k, \cdot) = \Gamma(\gamma, \cdot) \circ \Gamma(k, \cdot)$ (`Γ_mul`) and the composition rule for $\cdot$. Put $\sigma = |G_x|^{-1} \sum_k h_k$. Then: - σ is an sc⁺-section, a finite sum of sc⁺-sections times a constant; - *equivariance*: $\sigma(t(\psi)) = \psi \cdot \sigma$ for every morphism ψ between points of $U(x)$, by reindexing $k \mapsto \gamma k$ and linearity of $\mu(\psi, \cdot)$; - its support lies in $\overline{V}$; - if $s(x)$ is fixed by G_x, then $\sigma(x) = s(x)$: $\Phi(k^{-1})x = x$, so $h_k(x) = \mu(k, s(x)) = s(x)$; - every bound $N(s) \le b$ for an auxiliary norm passes to σ: $N(h_k(y)) = N(s(\Phi(k^{-1})y)) \le b$ by invariance of N, and the average of vectors of norm at most b has norm at most b by subadditivity and homogeneity.

The natural extension Chapter12/ScPlusSectionFunctor · EpStrongBundle.natExtension. For a section σ and y an object, if some morphism φ has $t(\varphi) = y$ and $s(\varphi) \in U(x)$, choose one and put $\tilde{\sigma}(y) = \varphi \cdot \sigma$; otherwise $\tilde{\sigma}(y) = 0$. It does not depend on the choice when σ is equivariant on $U(x)$ Chapter12/ScPlusSectionFunctor · EpStrongBundle.natExtension_eq: two choices φ, φ' differ by the morphism $\varphi^{-1}\varphi'$ between points of $U(x)$, and equivariance moves σ along it. On $U(x)$ it is σ Chapter12/ScPlusSectionFunctor · EpStrongBundle.natExtension_of_mem (choose the identity), it is functorial Chapter12/ScPlusSectionFunctor · EpStrongBundle.natExtension_isFunctorial (for $\psi : y \to y'$ and a choice φ at y, $\psi\varphi$ is a choice at y'), and it vanishes off the saturation of supp σ Chapter12/ScPlusSectionFunctor · EpStrongBundle.natExtension_eq_zero.

Theorem 12.3.3 (narrower) Chapter12/ScPlusSectionFunctor · EpStrongBundle.theorem_12_3_3, p. 581. Hypotheses: X admits sc-smooth bump functions (pointwise reading); $|X|$ is paracompact; N is an auxiliary norm; x is a smooth object; $e \in W_x$ is smooth with $\mu(g, e) = e$ for all $g \in G_x$; $\hat{O} \ni |x|$ is open in $|X|$; $\varepsilon > 0$. Conclusion: $e \in W_{0,1}$, and there is an sc$^+$-section functor σ with supp $\sigma \subset \pi^{-1}(\hat{O})$, $\sigma(x) = e$ and $N(\sigma(y)) \le N(e) + \varepsilon$ for all y.

Proof.

Step 1, a good neighbourhood. Apply the Chapter 7 lemma to the open $\pi^{-1}(\hat{O}) \ni x$: R on $U(x) \subset \pi^{-1}(\hat{O})$, $V \ni x$ invariant, $\overline{V} \subset U(x)$, $\overline{V}$ proper.

Step 2, a local section through e. By Theorem 12.3.2 (1) the object M-polyfold admits bump functions, and Part I's Lemma 5.3.3 Chapter5/BumpFunctions · lemma_5_3_3 gives: $e \in W_{0,1}$, and an sc$^+$-section s of the object bundle with $s(x) = e$, support in V and $N(s(y)) \le N(e) + \varepsilon$. The text builds this section as the constant section e in a chart times a cut-off β and controls its norm by continuity; Lemma 5.3.3 is that construction in Part I, so no separate cut-off is needed.

Step 3, average. The equivariant average σ' of s: an sc$^+$-section, equivariant on $U(x)$, with support in $\overline{V}$; since $s(x) = e$ is fixed by G_x, $\sigma'(x) = e$; and the bound $N(e) + \varepsilon$ passes. The text's average is the same sum, written $\frac{1}{|G|} \sum_g g * (\beta s_0)$.

Step 4, extend by Remark 12.3.5 (below): the natural extension of σ' is an sc$^+$-section functor, equal to σ' on $U(x)$, so its value at x is e; its support lies in sat(supp σ') $\subset$ sat$(U(x)) \subset \pi^{-1}(\hat{O})$; and it keeps the bound. □

Narrower by the pointwise reading of bump functions, which Step 2 needs (Part I's Lemma 5.3.3 is stated with pointwise bump functions). *Kept and unused*: the paracompactness of $|X|$. The text needs it only for the existence of an auxiliary norm, which is here a hypothesis.

Remark 12.3.4 (explicit) Chapter12/ScPlusSectionFunctor · EpStrongBundle.remark_12_3_4, p. 584. For a functorial section σ and $g \in G_x$, $\mu(g, \sigma(x)) = \sigma(x)$: functoriality at the morphism $g : x \to x$. So the invariance of e in Theorem 12.3.3 cannot be dropped, and sc$^+$-section functors cannot achieve transversality at points with isotropy, which is the remark's point. The rest of the remark is commentary.

Remark 12.3.5 (explicit) Chapter12/ScPlusSectionFunctor · EpStrongBundle.remark_12_3_5, p. 584. Let R be a natural representation on $U(x)$, $\overline{V} \subset U(x)$ with $\overline{V}$ proper, and σ an sc$^+$-section with support in $\overline{V}$, equivariant under the morphisms between points of $U(x)$. Then the natural extension $\tilde{\sigma}$ is an sc$^+$-section functor, equal to σ on $U(x)$, with support in sat(supp σ), and for every auxiliary norm N and $b \ge 0$, $N(\sigma) \le b$ implies $N(\tilde{\sigma}) \le b$.

Proof. Functoriality and the value on $U(x)$ are the properties of the natural extension above.

sc⁺, near a point y_0 of the saturation. There is a morphism φ_0 with $t(\varphi_0) = y_0$, $s(\varphi_0) \in U(x)$. Let τ be the local inverse of t on the sheet of φ_0, on a neighbourhood O of y_0 with $s(\tau(O)) \subset U(x)$. For $y \in O$, $\tau(y)$ is a morphism into y from a point of $U(x)$, so $\tilde\sigma(y) = \tau(y) \cdot \sigma$ by independence of the choice; this is sc-smooth into $W[1]$ by the smoothness lemma.

sc⁺, near a point y_0 off the saturation of $\operatorname{supp}\sigma$. This saturation is closed, because $\operatorname{supp}\sigma \subset \overline{V}$ is proper `Chapter7/ProperSubsets · isClosed_saturation_of_isProperSubset`; so y_0 has a neighbourhood off it, where $\tilde\sigma = 0$, the zero section, which is sc⁺. The two cases cover all y_0, since a point of the saturation of $\operatorname{supp}\sigma$ lies in the saturation of $U(x)$. Locality concludes.

Support. Off the closed set $\operatorname{sat}(\operatorname{supp}\sigma)$, $\tilde\sigma = 0$.

Bound. $N(\tilde\sigma(y)) = N(\varphi \cdot \sigma) = N(\sigma(s(\varphi))) \le b$ by invariance of N, and $N(0) = 0 \le b$. □

Explicit: the text's section is $f \cdot s$ with a cut-off f, and its "controlled" norm is a bound. In the formal statement the section is already cut off (its support lies in $\overline{V}$), and the control is the bound b. The properness of $\overline{V}$, which the text has from Theorem 12.2.6, is a hypothesis, supplied in every application by the Chapter 7 lemma.

XII.12 Definition 12.3.6 (2017: 12.8), Proposition 12.3.7 (2017: 12.2) and Corollary 12.3.8 (2017: 12.1): sc⁺-sections over the boundary, and their local extension

Theorem 12.3.9 extends an sc⁺-section functor given on ∂X to all of X. The text first says what an sc⁺-section over the boundary is (Definition 12.3.6), extends it locally in a tame local model by an inclusion–exclusion formula (Proposition 12.3.7), and makes the local extension equivariant under a finite group (Corollary 12.3.8). The formalization keeps all three, in a local model; Part I's Theorem 5.4.2 (Part V) is assembled from Proposition 12.3.7, and Theorem 12.3.9 (§XII.13) uses Part I's local extension.

The local model. Let E be an sc-Banach space with a partial quadrant C and a tame presentation $T : E \cong \mathbb{R}^n \oplus W$ with $C = T^{-1}([0,\infty)^n \oplus W)$. A tame local strong bundle model is $K = R(U \lhd F) \to O$: $U \subset C$ relatively open, R a strong bundle retraction of $U \lhd F$, linear on fibres, whose base retraction r is tame with respect to T, and $O = r(U)$. For $z \in O$, $I(z) = \{i : t_i(z) = 0\}$ is the set of vanishing coordinates (`zeroSet`), and ∂O is the set of $z \in O$ of nonzero degeneracy index `Chapter12/LocalBoundaryExtension · retractBoundary`, equivalently with $I(z) \neq \emptyset$ `Chapter12/LocalBoundaryExtension · mem_retractBoundary_iff`. A section of K over a subset is read as a map $s : E_0 \to E_0 \times F_1$ with first component the base point.

Definition 12.3.6, local form (restated) `Chapter12/LocalBoundaryExtension · IsBoundaryScPlusSectionOn`, p. 584. A section s over $D \subset \partial O$ is an sc⁺-section over the boundary when for every $x \in D$ and $i \in I(x)$, there is an open $V \ni x$ such that the face germ $O \cap V \cap \{t_i = 0\}$ is an sc-retract of C and s restricted to it is an sc⁺-section of K `Chapter12/LocalBoundaryExtension · IsScPlusOnFaceNear`. The text says "an sc⁺-section on each local face"; the faces of a tame retract are sc-retracts near the point, by Chapter 2's corner germs, and the formal definition carries that as part of the clause, so that "sc⁺ on the face" makes sense. Witness of the quantifier over models and presentations: the zero section is an sc⁺-section over the boundary in every tame model `Chapter12/LocalBoundaryExtension · isBoundaryScPlusSectionOn_zero`, since 0 is sc⁺ on every sc-retract `Chapter12/LocalBoundaryExtension · isScPlusSection_zero_local`.

Definition 12.3.6, ep-groupoid form (restated) Chapter12/ScPlusExtension · EpStrongBundle.IsBoundaryScPlusSection. A section s of $W|\partial X$ is an sc$^+$-section over the boundary when it is one for the object bundle in the sense of Part I's Definition 5.4.1 (Part V): $P(s(x)) = x$, $s(x) \in W_{0,1}$ for $x \in \partial X$, and in every tame strong bundle chart and every tame presentation, the local representative is an sc$^+$-section over the boundary in the local form at every boundary point of the chart. The local faces are read chart-wise, as in Definition 5.4.1; the definition does not involve μ. **An sc$^+$-section functor of** $W|\partial X$, as Theorem 12.3.9 uses it Chapter12/ScPlusExtension · EpStrongBundle.IsBoundaryScPlusSectionFunctor, adds $s(t(\varphi)) = \mu(\varphi, s(s(\varphi)))$ for every morphism φ with $s(\varphi) \in \partial X$; then $t(\varphi) \in \partial X$ as well, because morphisms keep the degeneracy index Chapter12/ScPlusExtension · EpGroupoid.tgt_mem_boundary_iff_p3x. Witness: the zero section is an sc$^+$-section functor of $W|\partial X$ in every strong bundle over an ep-groupoid Chapter12/ScPlusExtension · EpStrongBundle.isBoundaryScPlusSectionFunctor_fiberZero, and of W Chapter12/ScPlusExtension · EpStrongBundle.isScPlusSectionFunctor_fiberZero_p3x.

The inclusion–exclusion extension. Fix $x_0 \in \partial O$ and $\sigma = I(x_0)$. For $I \subseteq \sigma$ and z near x_0, let z_I be z with the coordinates t_i, $i \in I$, set to 0 (`cornerKill`), and then retracted by r. Then

$$\tilde{s}(z) = R\Big(z,\ \sum_{\emptyset \neq I \subseteq \sigma} (-1)^{|I|+1}\, s(z_I)\Big)$$

Chapter12/LocalBoundaryExtension · boundaryExtension, the text's sum written with the retraction applied once at the end. Its base component is z Chapter12/LocalBoundaryExtension · boundaryExtension_fst; its fibre component is the text's sum projected by $A(z)$ Chapter12/LocalBoundaryExtension · boundaryExtension_toBase_snd; it lies in $K[1]$ Chapter12/LocalBoundaryExtension · boundaryExtension_mem.

The corner kills. The coordinates of z_I before retraction are 0 on I and $t_i(z)$ elsewhere Chapter12/LocalBoundaryExtension · coord_cornerKill; killing the empty set changes nothing Chapter12/LocalBoundaryExtension · cornerKill_empty; and if $t_{i_0}(z) = 0$, killing $I \cup \{i_0\}$ is killing I Chapter12/LocalBoundaryExtension · cornerKill_insert_of_coord_eq_zero.

Each term is sc-smooth Chapter12/LocalBoundaryExtension · exists_isScSmooth_faceTerm. For $\emptyset \neq I \subseteq \sigma$, $z \mapsto s(z_I)$ is sc-smooth into $E \times F_1$ near x_0 on C: $z \mapsto z_I$ is the corner retraction of the face $\{t_i = 0, i \in I\}$ Chapter2/CornerGerms · corner_retraction followed by r, an sc-smooth map of a neighbourhood of x_0 in C into the face germ at x_0; and s is sc$^+$ on that face germ by hypothesis (for $|I| > 1$ the intersection of faces is a face of a face, and the hypothesis on single faces gives sc$^+$ on it by restriction). The scalar multiples and sums are sc-smooth (`ScBanach.p3bSmulOp`, `IsScSmooth.p3bConstSmul`) Chapter12/LocalBoundaryExtension · ScBanach.p3bSmulOp Chapter12/LocalBoundaryExtension · IsScSmooth.p3bConstSmul.

The cancellation Chapter12/LocalBoundaryExtension · sum_powerset_erase_empty_alternating. Let v be a function on subsets of σ and $i_0 \in \sigma$ with $v(I \cup \{i_0\}) = v(I)$ for all $I \subseteq \sigma$. Then

$$\sum_{\emptyset \neq I \subseteq \sigma} (-1)^{|I|+1} v(I) = v(\emptyset).$$

Proof. The full alternating sum $\sum_{I \subseteq \sigma} (-1)^{|I|} v(I)$ vanishes: split the subsets into those not containing i_0 and their unions with $\{i_0\}$ (`sum_powerset_insert`); paired terms have equal v and opposite signs. Splitting off $I = \emptyset$ and changing sign gives the claim. □

Proposition 12.3.7 (stronger) Chapter12/LocalBoundaryExtension · proposition_12_3_7_of_faces_at, p. 585. Let $K \to O$ be a tame local strong bundle model, $x_0 \in \partial O$, and s a section that is sc$^+$ on the face germs

at x_0 itself: for every $i \in I(x_0)$, s is sc$^+$ on $O \cap V \cap \{t_i = 0\}$ for some open $V \ni x_0$. Then there is an open $V \ni x_0$ such that $O \cap V$ is an sc-retract of C, $\tilde{s}$ is an sc$^+$-section of K over $O \cap V$, and $\tilde{s} = s$ on $\partial O \cap V$.

Proof. Step 1, the neighbourhood. V is the intersection of: an open $Z \ni x_0$ on which $I(z) \subseteq \sigma$ (coordinates that are positive at x_0 stay positive nearby, `eventually_zeroSet_subset`); for each nonempty $I \subseteq \sigma$, an open $N_I \ni x_0$ on which z_I stays in the domain where its term is sc-smooth; and the domains V_i of the face germs. Finitely many open sets, so V is open. *Step 2, sc-retract.* $O \cap V$ is an sc-retract of C, with retraction r restricted (`r.restrict`). *Step 3, sc$^+$.* By `isScSmoothRetractMap_iff_exists` it suffices that $z \mapsto \tilde{s}(z)$ is sc-smooth into $(U \lhd F)[1]$ on $O \cap V$: the alternating sum is sc-smooth (`IsScSmooth.finsetSum`), paired with the identity (`scPair`), and R is sc-smooth on level $[1]$ (`isScSmooth_one` of the strong bundle retraction). *Step 4, equality on the boundary.* Let $z \in \partial O \cap V$. Then $I(z) \neq \emptyset$ and $I(z) \subseteq \sigma$ by Step 1; pick $i_0 \in I(z)$. Since $t_{i_0}(z) = 0$, $z_{I \cup \{i_0\}} = z_I$ for all I; with $v(I) = s(z_I)$, the cancellation gives $\sum_{\emptyset \neq I \subseteq \sigma} (-1)^{|I|+1} s(z_I) = s(z_\emptyset) = s(z)$, the last because $z_\emptyset = r(z) = z$ for $z \in O$. Finally $R(z, s(z)) = s(z)$ because $s(z) \in K[1]$ and R fixes its image. □

Stronger: the text asks s to be sc$^+$ on the local faces at every boundary point near x_0; the proof uses only the face germs at x_0, because every face through a nearby boundary point is a face through x_0 (Step 1). **The text's form** (same) `Chapter12/LocalBoundaryExtension · proposition_12_3_7`: for an open V_0 and s an sc$^+$-section over $\partial O \cap V_0$ in the sense of Definition 12.3.6, every $x_0 \in \partial O \cap V_0$ has an open $V \ni x_0$ and an sc$^+$-section s' over $O \cap V$ with $s' = s$ on $\partial O \cap V$. It follows by applying the stronger form at x_0. The text writes the model on $\mathbb{R}^n \oplus H$; here it is any tame presentation T.

Non-degenerate witness `Chapter12/LocalBoundaryExtension · proposition_12_3_7_nonvacuous`: for every sc-Banach spaces W, F, the partial quadrant $C = [0, \infty) \oplus W$ with the identity presentation, $U = C$, the identity strong bundle retraction `Chapter12/LocalBoundaryExtension · isStrongBundleRetraction_id_p3b` (tame), the point $0 \in \partial O$, and the zero section, which is an sc$^+$-section over all of ∂O. Here $\partial O = \{0\} \oplus W \neq \emptyset$, so the hypotheses hold in a case with boundary.

Local bundle actions (explicit) `Chapter12/LocalBoundaryExtension · LocalBundleAction`. Corollary 12.3.8 assumes that a finite group "acts" on O with a lift to K. The formalization makes this a structure: a finite group G acting on E_0 by maps $x \mapsto g * x$ that are sc-smooth maps of the retract O, with $1 * x = x$ and $(gh) * x = g * (h * x)$ on O; and a lift $p \mapsto g * p$ on $E_0 \times F_1$, sc-smooth on $K[1]$, covering the action, linear on fibres over O, with the same unit and composition laws on $K[1]$. Witness: the trivial action of any group `Chapter12/LocalBoundaryExtension · LocalBundleAction.trivial`. In the applications (§XII.13) the action is the natural representation of G_x and its lift through μ.

The average `Chapter12/LocalBoundaryExtension · LocalBundleAction.average`: for a section s',

$$\hat{s}(x) = \Big(x,\ \frac{1}{|G|} \sum_{g \in G} \mathrm{pr}_2\big(g^{-1} * s'(g * x)\big)\Big).$$

A sum of vectors of $K[1]$ over the same point, with real coefficients, stays in $K[1]$ `Chapter12/LocalBoundaryExtension · mem_strongShiftOne_sum_smul`, because $K[1]$ is the image of a fibrewise linear retraction.

Corollary 12.3.8 (explicit) `Chapter12/LocalBoundaryExtension · corollary_12_3_8`, p. 585. Let $K \to O$ be a tame local model with a local bundle action of a finite G, $x_0 \in \partial O \cap V_0$ fixed by G, $\partial O \cap V_0$ invariant, and s an sc$^+$-section over $\partial O \cap V_0$ that is equivariant: $s(g * x) = g * s(x)$. Then there are an open $V \ni x_0$

with $O \cap V$ invariant and an sc⁺-section $\hat{s}$ over $O \cap V$, equivariant, with $\hat{s} = s$ on $\partial O \cap V$.

Proof. Step 1. Proposition 12.3.7 at x_0 gives V_1 and an extension $\tilde{s}$ on $O \cap V_1$. *Step 2, an invariant neighbourhood.* $V = \bigcap_g (g*)^{-1}(V_1 \cap V_0)$ near x_0, open by continuity of the action and containing x_0 because x_0 is fixed; $O \cap V$ is invariant. *Step 3, average.* $\hat{s}$ is the average of $\tilde{s}$. It is sc⁺: each term $g^{-1} * \tilde{s}(g * x)$ is a composite of sc-smooth maps into $K[1]$, and the sum stays in $K[1]$. *Step 4, equivariance*: reindexing $g \mapsto gh$, with the composition law of the lift. *Step 5, extension.* On $\partial O \cap V$, $g * x \in \partial O \cap V_1$ by invariance, so $\tilde{s}(g * x) = s(g * x) = g * s(x)$, and each term is $g^{-1} * g * s(x) = s(x)$; the average of $|G|$ copies of $s(x)$ is $s(x)$. □

Explicit: (a) "acts with a lift" is the structure above; (b) that G fixes x_0, true of an isotropy group, is a hypothesis; (c) the text's "invariant" section is read as equivariant, the only reading under which the average extends s.

XII.13 Theorem 12.3.9 (2017: 12.8): extension of sc⁺-section functors from the boundary

Theorem 12.3.9 (same) `Chapter12/ScPlusExtension · EpStrongBundle.theorem_12_3_9`, p. 586. Let $(P : W \to X, \mu)$ be a strong bundle over an ep-groupoid whose object bundle is tame (every object lies in a tame strong bundle chart, as in Part I's Theorem 5.4.2), with $|X|$ paracompact and X admitting sc-smooth partitions of unity (Definition 7.5.5: for every cover by saturated open sets, an sc-smooth partition of unity subordinate to it and constant along morphisms). Let s be an sc⁺-section functor of $W|\partial X$ and $U \supset \partial X$ a saturated open set. Then (1) there is an sc⁺-section functor $\tilde{s}$ of W with $\operatorname{supp} \tilde{s} \subset U$ and $\tilde{s} = s$ on ∂X; (2) if N is an auxiliary norm and $N(s(x)) < \delta$ for all $x \in \partial X$, then $\tilde{s}$ can be chosen with $N(\tilde{s}(x)) \le \delta$ for all x. The Lean statement takes the object and morphism types in the lowest universe, where Definition 7.5.5 is stated.

The proof has a local step, a gluing and a bound.

Bump functions from partitions of unity (extra) `Chapter12/ScPlusExtension · EpGroupoid.admitsBumpFunctionsPointwise_of_hasScPartitionsOfUnity`. An ep-groupoid with sc-smooth partitions of unity admits sc-smooth bump functions in the pointwise reading. *Proof.* For x in a saturated open U, take R and an invariant $V \ni x$ with $\overline{V} \subset R.U \subset U$, $\overline{V}$ proper (§XII.10). The saturation K of $\overline{V}$ is closed (properness) and contained in U (saturated). The two saturated open sets U and $X \setminus K$ cover X (complements of saturated sets are saturated `Chapter12/ScPlusExtension · EpGroupoid.isSaturated_compl_p3x`). A subordinate partition of unity $\{\rho_U, \rho_{X\setminus K}\}$ has $\rho_{X\setminus K} = 0$ on $K \ni x$, so $\rho_U(x) = 1$; ρ_U is sc-smooth, invariant and supported in U. □ The text uses this tacitly when it says "using Theorem 12.3.2 (2)"; by Theorem 12.3.2 (1) `Chapter12/BumpEp · EpGroupoid.theorem_12_3_2_1` the object M-polyfold then admits bump functions, which Part I's local extension needs. A two-set partition of unity is indexed by the two values of `Bool`, and one of its functions is 1 where the other vanishes `Chapter12/ScPlusExtension · EpGroupoid.partitionOfUnity_true_eq_one_p3x`.

Gluing sections (extra). For a partition of unity (ρ_i) of X and sections σ_i, the section $\sum_i \rho_i \sigma_i$ `Chapter12/ScPlusExtension · glueSection` is computed pointwise `Chapter12/ScPlusExtension · glueSection_apply`, is a section `Chapter12/ScPlusExtension · isSection_glueSection`, is locally a finite sum `Chapter12/ScPlusExtension · glueSection_finsum_eq_sum`, and: - takes the value v at y when every σ_i with $\rho_i(y) \neq 0$ takes the value v there `Chapter12/ScPlusExtension · glueSection_eq_of`, since $\sum_i \rho_i(y) = 1$; - has support in $\bigcup_i (\operatorname{supp} \rho_i \cap \operatorname{supp} \sigma_i)$ `Chapter12/ScPlusExtension · sectionSupport_glueSection_subset`; - is an

sc⁺-section when the σ_i are Chapter12/ScPlusExtension · isScPlusSection_glueSection: near each point it is a finite sum of products of sc-smooth functions with sc⁺-sections; - is functorial when the σ_i are and the ρ_i are constant along morphisms Chapter12/ScPlusExtension · EpStrongBundle.isFunctorialSection_glueSection, by linearity of $\mu(\varphi,\cdot)$; an invariant function times a functorial section is functorial Chapter12/ScPlusExtension · EpStrongBundle.isFunctorialSection_sectionSmul_p3x; together, an sc⁺-section functor Chapter12/ScPlusExtension · EpStrongBundle.isScPlusSectionFunctor_glueSection.

The local step Chapter12/ScPlusExtension · EpStrongBundle.exists_local_functor_extension. Assume the object bundle tame and bump functions on the objects. For $x \in \partial X$ in a saturated open U, there are a saturated open $U' \ni x$ and an sc⁺-section functor σ with $\operatorname{supp}\sigma \subset U$ and $\sigma = s$ on $U' \cap \partial X$.

Step 1, a good neighbourhood. R on $R.U \subset U$, $V \ni x$ invariant, $\overline{V} \subset R.U$, $\overline{V}$ proper.

Step 2, Part I's local extension. In a tame strong bundle chart at x, Part I's local extension Chapter5/BoundaryExtension · StrongBundle.exists_local_extension (Proposition 12.3.7 read in the chart, Part V) gives an open $U_1 \ni x$ and an sc⁺-section σ_0 of the object bundle with $\sigma_0 = s$ on $U_1 \cap \partial X$. A bump function $\beta : X \to [0,1]$ of Part I's Proposition 5.5.3 Chapter5/BumpFunctions · proposition_5_5_3, $\equiv 1$ near x and supported in $V \cap U_1$, cuts it off: $\sigma_1 = \beta\sigma_0$ is an sc⁺-section supported in V, equal to s on $W_1 \cap \partial X$ where $W_1 = \operatorname{int}\{\beta = 1\} \cap U_1 \ni x$.

Step 3, average. The equivariant average σ_2 of σ_1 over G_x (§XII.11) Chapter12/ScPlusExtension · EpStrongBundle.exists_equivariant_average_p3x is equivariant on $R.U$, supported in $\overline{V}$, and takes the value w at every point where all translates take the value w. Put $W_2 = \bigcap_k R.U \cap \Phi(k)^{-1}(W_1)$, an open neighbourhood of x ($\Phi(k)$ fixes x). At $y \in W_2 \cap \partial X$, each translate is $\mu(\Gamma(k,y'),\sigma_1(y'))$ with $y' = \Phi(k^{-1})y \in W_1 \cap \partial X$ (morphisms preserve ∂X), hence $\mu(\Gamma(k,y'),s(y')) = s(\Phi(k)y') = s(y)$ by functoriality of s on ∂X. So $\sigma_2 = s$ on $W_2 \cap \partial X$. This is Corollary 12.3.8 in its natural-representation form, with the lift given by μ.

Step 4, extend by Remark 12.3.5 Chapter12/ScPlusSectionFunctor · EpStrongBundle.remark_12_3_5: the natural extension σ of σ_2 is an sc⁺-section functor supported in $\operatorname{sat}(\overline{V}) \subset U$, equal to σ_2 on $R.U$. Put $U' = \operatorname{sat}(W_2)$, open and saturated. At $y \in U' \cap \partial X$, y is joined by φ to a point $y' \in W_2$, also in ∂X; $\sigma(y) = \mu(\varphi^{-1},\sigma(y')) = \mu(\varphi^{-1},s(y')) = s(y)$ by functoriality of σ and of s. □

The extension Chapter12/ScPlusExtension · EpStrongBundle.exists_extension_of_tameCharts: under the hypotheses of Theorem 12.3.9 without the norm, clause (1). *Step 1.* Bump functions on the objects, from the partitions of unity (above). *Step 2, a cover.* For $x \in \partial X$, the local step gives U'_x and σ_x supported in U. For $x \notin \partial X$, take the saturated open $X \setminus \partial X$ Chapter12/ScPlusExtension · EpGroupoid.isSaturated_compl_boundary_p3x with the zero section. These sets cover X. *Step 3, glue.* Take an sc-smooth partition of unity (ρ_x) subordinate to the cover, constant along morphisms, and $\tilde{s} = \sum_x \rho_x\sigma_x$, an sc⁺-section functor. *Step 4, properties.* On ∂X: the interior pieces have $\rho = 0$ there (their support lies in $X \setminus \partial X$), and every boundary piece with $\rho_x(y) \neq 0$ has $y \in U'_x$, so $\sigma_x(y) = s(y)$; hence $\tilde{s}(y) = s(y)$. Support: every σ_x is supported in U (the zero section trivially). □

The bound Chapter12/ScPlusExtension · EpStrongBundle.exists_extension_bounded_of_tameCharts, clause (2). *Step 1.* $\tilde{s}$ from (1). *Step 2, the open set.* $V = \{y : N(\tilde{s}(y)) < \delta\}$: $\tilde{s}$ is an sc⁺-section, so $y \mapsto \tilde{s}(y) \in W_{0,1}$ is continuous and $N \circ \tilde{s}$ is continuous; V is open, saturated by functoriality of $\tilde{s}$ and invariance of N, and contains ∂X by the hypothesis. *Step 3, a cut-off.* A partition of unity for the two-set cover $\{V, X \setminus \partial X\}$ gives β, sc-smooth, invariant, with $\operatorname{supp}\beta \subset V$ and $\beta = 1$ on ∂X (the other function vanishes there). *Step 4.* $\beta\tilde{s}$ is an sc⁺-section functor, equal to s on ∂X, supported in U, and $N(\beta\tilde{s}(y)) = \beta(y)N(\tilde{s}(y)) \leq \delta$: where $\beta(y) \neq 0$, $y \in V$; $\beta \leq 1$. □

Where the formal proof departs from the text. (a) The text obtains bump functions from Theorem 12.3.2 (2); here they come from the assumed partitions of unity, so no hypothesis is added. (b) The text's bound uses a second neighbourhood V' with $\overline{V'} \subset V$; the two-set partition of unity makes it unnecessary. (c) The local extension is Part I's (Theorem 5.4.2's local step), which is Proposition 12.3.7 in a chart; the averaging of Corollary 12.3.8 is done with the natural representation directly.

Hypotheses. All are the text's. The paracompactness of $|X|$ is kept and unused, since partitions of unity are assumed. **Witness for all hypotheses together** `Chapter12/ScPlusExtension · EpStrongBundle.theorem_12_3_9_hypotheses_rn`: the trivial bundle $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ over the trivial ep-groupoid of $\mathbb{R}^n$, the zero section and $U = X$. This witness is degenerate: $\mathbb{R}^n$ is modelled on all of $\mathbb{R}^n$, so $\partial X = \emptyset$ and the boundary data are vacuous. With boundary, the data of the statement are inhabited on every X (the zero section functor of $W|\partial X$ above, $U = X$), and the local construction has the non-degenerate witness of Proposition 12.3.7 on the quadrant $[0, \infty) \oplus W$ (§XII.12). Since Theorem 12.3.9 adds no hypothesis to the text's, the witness serves only as a consistency check.

XII.14 Definition 12.4.1, Theorem 12.4.2 and Lemma 12.4.4 (2017: Definition 12.9, Theorem 12.9, Lemma 12.1): compactness

§12.4 states the compactness notions of the Fredholm theory on ep-groupoids. All are statements about orbit sets $|A| = \pi(A)$ in $|X|$ and their closures, and the formal proofs consist of Part I's local compactness at zeros (Theorem 5.2.2) and two facts on closures in $|X|$, which the text states as Lemma 12.4.4 after it uses them. The lemma is given first here.

Lemma 12.4.4 (same), p. 589. (1) `Chapter12/CompactnessEp · EpGroupoid.lemma_12_4_4_1`: for a saturated set Σ of objects, $\mathrm{cl}_{|X|}\, \pi(\Sigma) = \pi(\mathrm{cl}_X\, \Sigma)$. (2) `Chapter12/CompactnessEp · EpGroupoid.lemma_12_4_4_2`: the same for any Σ with compact closure in X.

Proof of (1). π is continuous, surjective and open (Proposition 7.1.8). For an open map, preimages commute with closures: $\pi^{-1}(\mathrm{cl}\, \pi(\Sigma)) = \mathrm{cl}\, \pi^{-1}(\pi(\Sigma))$. Since Σ is saturated, $\pi^{-1}(\pi(\Sigma)) = \Sigma$. Applying π and using surjectivity, $\mathrm{cl}\, \pi(\Sigma) = \pi(\pi^{-1}(\mathrm{cl}\, \pi(\Sigma))) = \pi(\mathrm{cl}\, \Sigma)$. *Proof of (2).* $\pi(\mathrm{cl}\, \Sigma)$ is compact, hence closed in the Hausdorff $|X|$, and contains $\pi(\Sigma)$; so $\mathrm{cl}\, \pi(\Sigma) \subset \pi(\mathrm{cl}\, \Sigma)$. The reverse inclusion is continuity of π. □

A consequence `Chapter12/CompactnessEp · EpGroupoid.isClosed_image_π_of_isSaturated`: the image of a closed saturated set is closed, by (1) with $\mathrm{cl}\, \Sigma = \Sigma$.

Definition 12.4.1 (same) `Chapter12/CompactnessEp · EpStrongBundle.HasCompactSolutionSetEp` `Chapter12/CompactnessEp · EpStrongBundle.IsProperFunctor` `Chapter12/CompactnessEp · EpStrongBundle.IsProperLtInftyFunctor`, p. 587. For a section functor f with solution set $S_f = \{x : f(x) = 0\}$: 1. f has *compact solution set* if $|S_f|$ is compact in $|X|$; 2. f is *proper* if $|S_f|$ is compact and for every auxiliary norm N there is a saturated open $U \supset S_f$ with $\mathrm{cl}_{|X|}\, |\{x \in U : N(f(x)) \le 1\}|$ compact; 3. f is *proper*$_{<\infty}$ if $|S_f|$ is compact and for every auxiliary norm N there is one saturated open $U \supset S_f$ with $\mathrm{cl}_{|X|}\, |\{x \in U : N(f(x)) \le C\}|$ compact for every $0 < C < \infty$.

"$N(f(x)) \le C$" is Part I's relation `AuxLe`, which does not hold when $f(x) \notin W_{0,1}$. It passes along morphisms `Chapter12/CompactnessEp · EpStrongBundle.auxLe_tgt_of_auxLe_src`: if $N(f(s(\varphi))) \le C$ then $N(f(t(\varphi))) \le C$, since $f(t(\varphi)) = \mu(\varphi, f(s(\varphi)))$, μ preserves $W_{0,1}$ and N is invariant. So the sublevel sets are saturated when U is.

Theorem 12.4.2 (same) Chapter12/CompactnessEp · EpStrongBundle.theorem_12_4_2, pp. 587–588. For an sc-Fredholm section functor f over an ep-groupoid with paracompact $|X|$, the three properties are equivalent. The Lean statement is a list of equivalent propositions [proper, compact solution set, proper$_{<\infty}$].

The order of the implications. The text's proof labels its three steps (3)□ (2), (2)□ (1), (1)□ (3). Their arguments are, as we read them, those of (3)□ (1), (1)□ (2), (2)□ (3) in the numbering of the definition: the first is "take $C = 1$", the second "drop the second clause", the third the construction below. The labels are presumably permuted; the formal proof follows the arguments, and the cycle closes either way.

(3)□ (1) Chapter12/CompactnessEp · EpStrongBundle.IsProperLtInftyFunctor.isProperFunctor: proper$_{<\infty}$ implies proper, with $C = 1$. *(1)□ (2)* Chapter12/CompactnessEp · EpStrongBundle.IsProperFunctor.hasCompactSolutionSetEp: the first clause.

(2)□ (3) Chapter12/CompactnessEp · EpStrongBundle.isProperLtInftyFunctor_of_hasCompactSolutionSetEp: let $|S_f|$ be compact and N an auxiliary norm.

Step 1, local compactness at zeros Chapter12/CompactnessEp · exists_nhds_isCompact_closure_auxLe. For an sc-Fredholm section f of a strong bundle over an M-polyfold (here the object bundle), an auxiliary norm N and a zero x, there is an open $V(x) \ni x$ such that $\mathrm{cl}\{y \in V(x) : N(f(y)) \le C\}$ is compact for every $C > 0$. *Proof.* Part I's local compactness at a zero (the local step of Theorem 5.2.2 Chapter5/Book2021 · theorem_5_2_2, exists_nbhd_isCompact_closure_bdd): in a chart c at x and a neighbourhood V, the set of $y \in V$ with $\|\mathrm{pr}_2 \Phi[1](f(y))\|_{F_1} \le b$ has compact closure for every b, by the contraction germ normal form of the sc-Fredholm germ at x. Near x, N dominates a multiple of the chart norm: $|w|_1 \le A\,N(w)$ (the lower bound of §XII.2). So $N(f(y)) \le C$ gives $|f(y)|_1 \le AC$, and the sublevel set of N lies in a set with compact closure.

Step 2, a finite cover. The open sets $\pi(V(x))$, $x \in S_f$, cover the compact $|S_f|$; choose finitely many, $x_1, \dots, x_m$, and put $U = \pi^{-1}(\bigcup_i \pi(V(x_i)))$, open and saturated, containing S_f.

Step 3, compactness. For every $C > 0$, $|\{x \in U : N(f(x)) \le C\}| \subset \bigcup_i \pi(\mathrm{cl}\{y \in V(x_i) : N(f(y)) \le C\})$: a point of U is joined by a morphism to a point y of some $V(x_i)$, and the sublevel condition passes along morphisms. The right side is a finite union of compact sets, hence compact and closed, so the closure of the left side is compact. □

Where the formal proof departs from the text. The text shrinks the neighbourhoods to ones with the natural action; this is not needed, because Step 3 only uses that sublevel sets are saturated. *Kept and unused*: the paracompactness of $|X|$, since all three properties quantify over the auxiliary norms, and their existence (Theorem 12.2.2) is not needed for the equivalence.

XII.15 Definition 12.4.3, Proposition 12.4.5 and Theorem 12.4.6 (2017: Definition 12.10, Proposition 12.3, Theorem 12.10): reflexive local compactness

Definition 12.4.3 (same) Chapter12/ReflexiveCompactnessEp · EpStrongBundle.HasReflexiveLocalCompactnessEp, pp. 588–589. A section functor f has the *ep-groupoid reflexive local compactness property* if for every reflexive auxiliary norm N and every object x there is an open $U(x) \ni x$ with $\mathrm{cl}_X\{y \in U(x) : N(f(y)) \le 1\}$ compact. The text's standing assumptions (reflexive $(0,1)$-fibres, f sc-smooth and regularizing) are hypotheses of the statements that use the definition, not part of it. Part I's Definition 5.2.6 (Part V) on

the object bundle implies it Chapter12/ReflexiveCompactnessEp · EpStrongBundle.hasReflexiveLocalCompactnessEp_of_strong: a reflexive auxiliary norm of the ep-groupoid is one of the object bundle (§XII.8).

Two tools.

Saturated sublevel sets Chapter12/ReflexiveCompactnessEp · EpStrongBundle.isSaturated_setOf_auxLe: for a functorial f and an auxiliary norm N, $\{y : N(f(y)) \le C\}$ is saturated (§XII.14); the intersection of saturated sets is saturated Chapter12/ReflexiveCompactnessEp · EpGroupoid.isSaturated_inter.

Compact closures from orbit sets Chapter12/ReflexiveCompactnessEp · EpGroupoid.isCompact_closure_of_isProperMap: if $t : s^{-1}(\overline{V_0}) \to X$ is proper and $A \subset V_0$ has $\mathrm{cl}_{|X|}\,|A|$ compact, then $\mathrm{cl}_X A$ is compact. *Proof.* X is metrizable, so it suffices that every sequence a_k in $\mathrm{cl}\,A$ has a subsequence converging in $\mathrm{cl}\,A$. *Step 1.* $\pi(a_k)$ lies in $\mathrm{cl}\,|A|$ (continuity of π), which is compact, so a subsequence converges in $|X|$ to some $\pi(q)$. *Step 2, lifting* Chapter12/ReflexiveCompactnessEp · EpGroupoid.exists_lift_tendsto: if $\pi(u_k) \to \pi(q)$ in $|X|$, there are objects v_k with $\pi(v_k) = \pi(u_k)$ and $v_k \to q$ in X. Take a decreasing neighbourhood basis V_n of q; since π is open, $\pi(V_n)$ is a neighbourhood of $\pi(q)$, so $\pi(u_k) \in \pi(V_n)$ for $k \ge K_n$; for each k let $m(k)$ be the largest $n \le k$ with $K_n \le k$, and choose $v_k \in V_{m(k)}$ over $\pi(u_k)$; $m(k) \to \infty$, so $v_k \to q$. *Step 3.* Morphisms $\varphi_k : a_k \to v_k$ have sources in $\mathrm{cl}\,A \subset \overline{V_0}$ and convergent targets $v_k \to q$; by properness (the lemma of §XII.5, `exists_subseq_of_isProperMap`), a subsequence converges to a morphism ψ; then $a_k = s(\varphi_k) \to s(\psi)$ along it, and $s(\psi) \in \mathrm{cl}\,A$, which is closed. □

Proposition 12.4.5 (stronger) Chapter12/ReflexiveCompactnessEp · EpStrongBundle.proposition_12_4_5, p. 590. For an sc-smooth section functor f that is regularizing, with reflexive fibres, the following are equivalent: 1. the reflexive local compactness property (Definition 12.4.3); 2. for every reflexive N and every $z \in |X|$ there is a saturated open $\tilde{U}$ with $z \in |\tilde{U}|$ and $|\,\mathrm{cl}_X\{y \in \tilde{U} : N(f(y)) \le 1\}|$ compact; 3. the same with $\mathrm{cl}_{|X|}\,|\{y \in \tilde{U} : N(f(y)) \le 1\}|$ compact.

Stronger: the equivalence holds for every functorial section Chapter12/ReflexiveCompactnessEp · EpStrongBundle.proposition_12_4_5_of_functorial; reflexive fibres, sc-smoothness and the regularizing property are hypotheses of the book's form that the proof does not use.

(2)□ (3). The sublevel set $\{y \in \tilde{U} : N(f(y)) \le 1\}$ is saturated (intersection of two saturated sets), so by Lemma 12.4.4 (1) its closure in $|X|$ is the image of its closure in X; the two compactness conditions are the same.

(1)□ (3). Given $z = \pi(x)$, take $U(x)$ from (1) and $\tilde{U} = \mathrm{sat}(U(x))$, open and saturated. Its sublevel set has the same orbit set as that of $U(x)$ (sublevel sets are saturated); by Lemma 12.4.4 (2), the closure in $|X|$ of the orbit set of the sublevel set of $U(x)$ is the image of its compact closure, hence compact.

(3)□ (1), which the text says is easily obtained. Given x, take $V_0 \ni x$ on which t is proper over $s^{-1}(\overline{V_0})$ (the properness clause of an ep-groupoid), $\tilde{U}$ from (3) for $z = \pi(x)$, and a point of $\tilde{U}$ over z, which may be taken to be x since $\tilde{U}$ is saturated. Put $U(x) = \tilde{U} \cap V_0$, open and containing x. Its sublevel set A lies in V_0, and $|A| \subset |\{y \in \tilde{U} : N(f(y)) \le 1\}|$ has compact closure in $|X|$; by the second tool, $\mathrm{cl}_X A$ is compact. □ The step is short in the formal proof only because the second tool, a lifting argument through the properness of t, carries it; that argument is what "easily obtained" leaves out.

Theorem 12.4.6 (stronger) Chapter12/ReflexiveCompactnessEp · EpStrongBundle.theorem_12_4_6, pp. 590–592. Hypotheses, as printed: X tame, $|X|$ paracompact, reflexive $(0,1)$-fibres, N a reflexive auxiliary norm, f an sc-Fredholm section functor with $|S_f|$ compact and the reflexive local compactness property, and U_∂ a saturated subset of ∂X, open in ∂X, containing $S_f \cap \partial X$, with $\mathrm{cl}_{|X|}\,|\{y \in U_\partial : N(f(y)) \le 1\}|$ compact. Conclusion: a saturated open $U \supset S_f$ with $U \cap \partial X = U_\partial$ and $\mathrm{cl}_{|X|}\,|\{x \in U : N(f(x)) \le 1\}|$ com-

pact. The text writes "U_∂ open in ∂X"; it is read as $U_\partial = W' \cap \partial X$ for an open W' of X, the subspace topology.

Stronger: the conclusion holds for every continuous section functor f with local compactness at the given N `Chapter12/ReflexiveCompactnessEp · EpStrongBundle.theorem_12_4_6_of_continuous`. Tameness, paracompactness and the Fredholm property beyond continuity are unused; reflexive fibres and the reflexivity of N are used once, for Step 0.

Proof, the text's, carried out in $|X|$.

Step 0, the sublevel set is closed. $A = \{x : N(f(x)) \le 1\}$ is closed in X, by Part I's Proposition 5.2.7 (2) (`StrongBundle.isClosed_setOf_auxLe`): a limit of points with $N(f(x_k)) \le 1$ has $f(x_k) \to f(x)$ on level 0 with $N(f(x_k))$ bounded, hence mixed convergent (Remark 12.2.9, Step 3), and $N(f(x)) \le \liminf N(f(x_k)) \le 1$ by reflexivity of N. A is saturated, so $\pi(A)$ is closed (§XII.14), and so is ∂X, which is closed and saturated.

Step 1, the boundary part. For each object q, local compactness gives an open $U(q) \ni q$ with $\mathrm{cl}\{y \in U(q) : N(f(y)) \le 1\}$ compact. The open sets $|U(q)|$ cover the compact $\mathrm{cl}\,|U_\partial \cap A|$; take finitely many, $q_1, \dots, q_m$, with union O_1. Put $O_t = O_1 \cup (|X| \setminus |A|)$, open.

Step 2, the interior part. The compact $|S_f|$ minus the open O_t is compact; it lies in $|X \setminus \partial X|$, because a zero in ∂X lies in $U_\partial \cap A$ and so in O_1. It is covered by the open sets $|U(x) \setminus \partial X|$, $x \in S_f \setminus \partial X$; take finitely many, with union O_2.

Step 3, the set U. Put $O_V = |W'| \cup |X \setminus \partial X|$, open, and $U = \pi^{-1}((O_t \cup O_2) \cap O_V)$, open and saturated. - $S_f \subset U$: a zero x lies in $O_t \cup O_2$ by Steps 1–2, and in O_V: if $x \in \partial X$, then $x \in U_\partial \subset W'$. - $U \cap \partial X = U_\partial$: if $x \in U \cap \partial X$, then $\pi(x) \in |W'|$ (it is not in $|X \setminus \partial X|$, since ∂X is saturated), so x is joined to a point of $W' \cap \partial X = U_\partial$, and $x \in U_\partial$ because U_∂ is saturated. Conversely, points of U_∂ lie in O_V, and in O_t (either in A, then in O_1 by Step 1, or not in A). - *Compactness*: $|\{x \in U : N(f(x)) \le 1\}| = |U \cap A|$ lies in $O_t \cup O_2$ intersected with $|A|$, hence in $O_1 \cup O_2$ intersected with $|A|$, which lies in the finite union T of the compact sets $\pi(\mathrm{cl}\{y \in U(q_i) : N(f(y)) \le 1\})$ and the corresponding sets for the interior points. T is compact and closed, so the closure of $|U \cap A|$ is compact. □

Hypotheses. None added. *Kept and unused* in the book's form: tameness, paracompactness, the Fredholm property beyond continuity. Witness of Definition 12.4.3: any section functor with Part I's reflexive local compactness property (Definition 5.2.6) on the object bundle, by the implication above; every hypothesis of Proposition 12.4.5 and Theorem 12.4.6 is a hypothesis of the text, so no witness beyond the text's is owed.

XII.16 The local strong bundle isomorphism of a morphism, and chart points carried along it (§12.5, pp. 592–594)

§12.5 orients sc-Fredholm section functors. Part I attaches to an sc-Fredholm section f of a strong bundle over an M-polyfold, at each smooth point x, the set $\mathrm{Lin}(f, x)$ of linearizations $(f - s_0)'(x)$, s_0 an sc$^+$-section with $s_0(x) = f(x)$, and the two-point set Or_x^f of orientations of the determinant line of any of them, all identified by the canonical isomorphisms of determinant lines along the convex set $\mathrm{Lin}(f, x)$ (Chapter 6, Part VI). The chapter's task is to make the morphisms act on these sets. The text does it in one sentence: a morphism $\varphi : x \to x'$ extends to an sc-diffeomorphism $\widehat{\varphi} : U(x) \to U(x')$ with a lift $\widehat{\Phi}$ to the bundle, and $\varphi_* S = \mu(\varphi, \cdot) \circ S \circ (T\varphi)^{-1}$ maps $\mathrm{Lin}(f, x)$ to $\mathrm{Lin}(f, x')$. The formalization reads

this sentence in Part I's chart points, which is where Lin lives, and the comparison of chart points is the bulk of §12.5's formal content. This section collects the tools; Lemma 12.5.1 is §XII.17.

Part I's chart points. In the project, $\mathrm{Lin}(f,x)$ is read in a *chart point* at x (`ChartPoint`, Part VI): a strong bundle chart around x with a level-1 point z of its model, through which T_xX is the tangent space T_zO of the retract and the fibre W_x is the fibre K_z of the model. $\mathrm{Lin}(f,x)$ is then a set of operators $T_zO \to K_z$ (`linSet`), and two chart points at the same x are compared by Part I's transfer maps of tangent spaces and fibres (`transferT`, `transferK`) and the induced bijection of orientation sets (`orTransfer`), which form a cocycle. At each smooth object of an ep-groupoid one chart point is chosen once `Chapter12/OrientationBundleEp · orPt`, and Or^f_x is read in it; restricting its chart to an open $V \ni x$ gives a chart point inside V `Chapter12/OrientationBundleEp · restrPt`. An sc-Fredholm section functor is functorial `Chapter12/OrientationBundleEp · EpStrongBundle.functorial_of_isScFredholmSectionFunctor`.

The isomorphism of a morphism `Chapter12/MorphismIso · EpStrongBundle.morIso`. Let $\sigma : x \to x'$ be a morphism, and choose a sheet of σ, an open neighbourhood of σ in the morphism space on which s and t are sc-diffeomorphisms onto open sets $s(\mathrm{sheet}) \ni x$ and $t(\mathrm{sheet}) \ni x'$ (`sheetAt`). Write $\tau = (t|_{\mathrm{sheet}})^{-1}$. Then

$$\mathrm{morIso}(\sigma) : W|t(\mathrm{sheet}) \to W|s(\mathrm{sheet}), \qquad y \mapsto s(\tau(y)), \qquad w \mapsto \mu(\tau(P(w))^{-1}, w)$$

is a local strong bundle isomorphism (`StrongBundle.LocalIso`: an sc-diffeomorphism of the bases with a strong bundle isomorphism over it, both with inverses). The ingredients: - the local section $y \mapsto \tau(y)^{-1}$ of s near x' `Chapter12/MorphismIso · EpStrongBundle.morInvSec`, which starts at y `Chapter12/MorphismIso · EpStrongBundle.src_morInvSec` and is sc-smooth `Chapter12/MorphismIso · EpStrongBundle.isScSmoothOn_morInvSec` (inversion is sc-smooth on an ep-groupoid); - the base map $s \circ \tau$, an sc-diffeomorphism $t(\mathrm{sheet}) \to s(\mathrm{sheet})$ with inverse $t \circ (s|_{\mathrm{sheet}})^{-1}$ `Chapter12/MorphismIso · EpStrongBundle.isScDiffeoOn_morBase`; - the bundle map is the action of the sc-smooth family $\tau(\cdot)^{-1}$ of morphisms, with inverse the action of $(s|_{\mathrm{sheet}})^{-1}$, both strong bundle maps (`sectionAct`).

The text's $\hat{\Phi}$ goes from $U(x)$ to $U(x')$; $\mathrm{morIso}(\sigma)$ is its inverse, in the direction in which charts at x are carried to charts at x' (Part I's transported chart, `LocalIso.transportChart`). Its properties: x' lies in its domain `Chapter12/MorphismIso · EpStrongBundle.tgt_mem_morIso` and goes to x `Chapter12/MorphismIso · EpStrongBundle.morIso_ϕ_tgt` (because $\tau(x') = \sigma$), with $\tau(x') = \sigma$ `Chapter12/MorphismIso · EpStrongBundle.tgtInv_tgt` and $x \in s(\mathrm{sheet})$ `Chapter12/MorphismIso · EpStrongBundle.src_mem_morIso`; on the fibre over x' the bundle map is $\mu(\sigma^{-1}, \cdot)$ `Chapter12/MorphismIso · EpStrongBundle.morIso_Φ_eq`; every functorial section f is invariant under it, $f = \Psi \circ f \circ \phi$ on $t(\mathrm{sheet})$ `Chapter12/MorphismIso · EpStrongBundle.eqOn_morIso`, because $f(y) = \mu(\tau(y), f(s(\tau(y))))$; and for composable $\varphi : x \to y$, $\psi : y \to z$, the composite of the isomorphisms of φ and ψ agrees near z with the isomorphism of $\psi \circ \varphi$ `Chapter12/MorphismIso · EpStrongBundle.germAgree_morIso_comp`: on the base because $\tau_\psi(y') \circ \tau_\varphi(\ldots)$ and $\tau_{\psi\varphi}(y')$ are both local inverses of t through $\psi\varphi$, hence agree near z, and on the bundle by $\mu(\psi\gamma, w) = \mu(\psi, \mu(\gamma, w))$. The construction is that of Chapter 10's `exists_localIso_mor` (Part X), with the data kept.

Chart points carried along a local isomorphism of a bundle to itself. Let $L : W|U \to W|U'$ be a local strong bundle isomorphism over $\phi : U \to U'$, and p a chart point at $x = \phi(x')$ whose chart lies in U'. The *carried chart point* $\mathrm{pullPt}(L,p)$ at x' is the chart point of the transported chart $\Psi' \circ \Phi$ (Part I's chart composed with the bundle map of L), with the same model, the same retraction and the same level-1 point z `Chapter12/ChartPull · StrongBundle.LocalIso.pullPt`. Its chart, point, tangent space and fibre are those of p `Chapter12/ChartPull · StrongBundle.LocalIso.pullPt_c Chapter12/ChartPull · StrongBundle.LocalIso.`

pullPt_z Chapter12/ChartPull · StrongBundle.LocalIso.pullPt_T Chapter12/ChartPull · StrongBundle.LocalIso.pullPt_K.

Linearizations agree Chapter12/ChartPull · StrongBundle.LocalIso.linSet_pullPt: if $f = \Psi \circ f \circ \phi$ on U, then $\mathrm{Lin}(f, x')$ read in $\mathrm{pullPt}(L, p)$ is $\mathrm{Lin}(f, x)$ read in p. *Proof.* The principal part of f in the transported chart is the principal part of $\Psi \circ f \circ \phi$ in the chart of p, which is that of f, so the two are the same map near z. For an sc⁺-section s_1 through $f(x')$, $(f - s_1)'$ read in the transported chart differs from $(f - s_0)'$ read in p (for any s_0 through $f(x)$) by the derivative of the difference of the two local sc⁺-representatives, which is an sc⁺-operator Chapter12/ChartPull · StrongBundle.LocalIso.exists_isScPlusOp_pullPt; and Lin is closed under adding sc⁺-operators (Part VI). So each set contains the other. This is the text's identity $\mu(\varphi, (f - s_0)'(x) \circ T\varphi^{-1}) = (f - s_1)'(x')$, read in the transported chart, where $T\varphi$ and $\mu(\varphi, \cdot)$ become identities.

A reading. The sections in Lin are global sc⁺-sections in the project, while the text uses a local section $s_1 = \hat{\Phi}_* s_0$. Any global sc⁺-section through $f(x')$ serves, and their existence is §12.5's standing hypothesis B.`HasScPlusSectionsThrough` (an sc⁺-section through every smooth fibre point), under which Part I proves $\mathrm{Lin}(f, x) \neq \emptyset$. Bump functions on the objects give it (Part III) Chapter3/IndexLocallyConstantLocal · MPolyfold.AdmitsBumpFunctions.hasScPlusSectionsThrough.

Transfers commute with carrying Chapter12/ChartPull · StrongBundle.LocalIso.transferT_pullPt Chapter12/ChartPull · StrongBundle.LocalIso.transferK_pullPt: Part I's transfer between two carried chart points is the transfer between the original ones, since it is defined from the derivative of the transition map of the charts and the transported charts have the same transition. The derivative of the base transition and the fibre transition carry over Chapter12/ChartPull · StrongBundle.LocalIso.baseDeriv_pullPt Chapter12/ChartPull · StrongBundle.LocalIso.fiberMap_pullPt. *Germs* Chapter12/ChartPull · StrongBundle.LocalIso.GermAgree: two pairs of composable local isomorphisms *agree near* x'' if their composites have the same base and bundle maps on a neighbourhood of x''. Then the transfer between the two doubly carried chart points is the identity Chapter12/ChartPull · StrongBundle.LocalIso.transferT_pullPt_pullPt Chapter12/ChartPull · StrongBundle.LocalIso.transferK_pullPt_pullPt, since the two transported charts coincide near the point; the derivative forms Chapter12/ChartPull · StrongBundle.LocalIso.baseDeriv_pullPt_pullPt Chapter12/ChartPull · StrongBundle.LocalIso.fiberMap_pullPt_pullPt.

The orientation map of a local isomorphism. For chart points q at x and q' at x', with an intermediate chart point a at x inside U': - the identifications of T_x and $T_{x'}$, and of the fibres, are cast between a chart point and its carried chart point Chapter12/OrientationBundleEp · StrongBundle.LocalIso.castT Chapter12/OrientationBundleEp · StrongBundle.LocalIso.castK; - Or^f_x read in a and $\mathrm{Or}^f_{x'}$ read in the carried chart point are the same set, since the two Lin agree Chapter12/OrientationBundleEp · StrongBundle.LocalIso.orPull; - the maps $T_x X \to T_{x'} X$ and $W_x \to W_{x'}$ of L read in q, q' are Part I's transfer from q to a, the cast to the carried point, and the transfer to q' Chapter12/OrientationBundleEp · StrongBundle.LocalIso.morT Chapter12/OrientationBundleEp · StrongBundle.LocalIso.morK; - the orientation map $\mathrm{orVia} : \mathrm{Or}^f_x(q) \to \mathrm{Or}^f_{x'}(q')$ is orTransfer from q to a, then orPull, then orTransfer to q' Chapter12/OrientationBundleEp · StrongBundle.LocalIso.orVia, and it is the conjugation of a line orientation by morT and morK Chapter12/OrientationBundleEp · StrongBundle.LocalIso.orVia_apply.

All three are independent of the intermediate chart point a Chapter12/OrientationBundleEp · StrongBundle.LocalIso.morT_eq Chapter12/OrientationBundleEp · StrongBundle.LocalIso.morK_eq Chapter12/OrientationBundleEp · StrongBundle.LocalIso.orVia_eq (the cocycle of transfers and the commutation of transfers with carrying), and composing the maps of L and L_2 gives the map of L_3 when $L \circ L_2$ and L_3 agree near the point Chapter12/OrientationBundleEp · StrongBundle.LocalIso.morT_comp Chapter12/

OrientationBundleEp · StrongBundle.LocalIso.morK_comp, by the germ lemma above.

Between two bundles (extra) Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.mpullPt. Theorem 12.5.7 compares two different strong bundles $Y \to U$ and $Y' \to U'$, through a strong bundle equivalence, and Theorem 12.5.3's last sentence carries orientations along a local isomorphism. The same construction works for a local strong bundle isomorphism $L : Y|U \to Y'|U'$ over an sc-diffeomorphism ϕ between different M-polyfolds: a chart point p of Y' at $\phi(b)$ inside U' is carried to the chart point $\mathrm{mpullPt}(L, p)$ of Y at b, in the transported chart. Under $f = \Psi \circ f' \circ \phi$ on U (the text's "$\hat{\hat{\Phi}}$ maps f to f'"): - $\mathrm{Lin}(f, b)$ in the carried chart point is $\mathrm{Lin}(f', \phi(b))$ in p Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.linSet_mpullPt, through an sc$^+$-operator difference Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.exists_isScPlusOp_mpullPt; - transfers commute with carrying Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.baseDeriv_mpullPt Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.fiberMap_mpullPt Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.transferT_mpullPt Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.transferK_mpullPt; - for two composites with the same germ, the four-term form Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.GermAgree₄ Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.baseDeriv_mpullPt₄ Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.fiberMap_mpullPt₄ Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.transferT_mpullPt₄ Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.transferK_mpullPt₄; - the cast Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.mcastT, the identification of orientation sets Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.morPull, the maps of tangent spaces and fibres Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.mmorT Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.mmorK, and the orientation map $\mathrm{Or}^{f'}_{\phi(b)} \to \mathrm{Or}^{f}_{b}$ Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.morVia, a conjugation Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.morVia_apply, independent of the intermediate chart point Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.mmorT_eq Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.morVia_eq.

For a bundle to itself the carried chart point is the one above Chapter12/ChartPullTwoBundles · StrongBundle.LocalIso.mpullPt_eq_pullPt.

The orientation map depends only on the germ (extra) Chapter12/OrientationGerm · StrongBundle.LocalIso.GermEq Chapter12/OrientationGerm · StrongBundle.LocalIso.morVia_germ. Two local isomorphisms L_1, L_3 *have the same germ at* b if their base maps and bundle maps agree on an open neighbourhood of b. Then they act alike on orientations at b. *Proof.* The chart points carried along L_1 and L_3 have, at b, base transition derivative $Dr(z)$ and fibre transition the identity on K_z, as from a chart point to itself Chapter12/OrientationGerm · StrongBundle.LocalIso.baseDeriv_mpullPt_germ Chapter12/OrientationGerm · StrongBundle.LocalIso.fiberMap_mpullPt_germ, because the two transported charts agree near b; so the transfers between them are identities Chapter12/OrientationGerm · StrongBundle.LocalIso.transferT_mpullPt_germ Chapter12/OrientationGerm · StrongBundle.LocalIso.transferK_mpullPt_germ, the maps of tangent spaces and fibres agree Chapter12/OrientationGerm · StrongBundle.LocalIso.mmorT_germ Chapter12/OrientationGerm · StrongBundle.LocalIso.mmorK_germ, and so do the conjugations. The text passes silently from one sheet of a morphism to another, and from the local isomorphism of an equivalence at one object to that at a nearby object; this lemma is what justifies it. Two sheets through one morphism σ have the same local inverse of t near $t(\sigma)$ Chapter12/OrientationGerm · EpGroupoid.Sheet.tgtInv_eq_near_or, because t is injective on each sheet and both inverses are continuous through σ.

XII.17 Lemma 12.5.1 (2017: 12.2): morphisms act on linearizations and on orientations

$T\varphi$ and $\mu(\varphi,\cdot)$ in the chosen chart points `Chapter12/OrientationBundleEp · EpStrongBundle.morTx` `Chapter12/OrientationBundleEp · EpStrongBundle.morKx`. For a morphism $\sigma : x \to x'$ between smooth objects, $T\sigma : T_xX \to T_{x'}X$ and $\mu(\sigma,\cdot) : W_x \to W_{x'}$ are read in the chosen chart points at x and x' as the composite of three maps: Part I's transfer from the chosen chart point at x to the chart point restricted to $s(\text{sheet})$, the identity to its chart point carried along $\text{morIso}(\sigma)$ at x', and the transfer from there to the chosen chart point at x'; they are morT and morK of $\text{morIso}(\sigma)$ `Chapter12/OrientationBundleEp · EpStrongBundle.morTx_eq` `Chapter12/OrientationBundleEp · EpStrongBundle.morKx_eq`. Lin in a chart point inside $s(\text{sheet})$ and in its carried chart point coincide `Chapter12/OrientationBundleEp · EpStrongBundle.linSet_pullPt_mor`, by the invariance of the functor f under $\text{morIso}(\sigma)$.

Functoriality in chart points. - *Composition* `Chapter12/OrientationBundleEp · EpStrongBundle.morTx_comp` `Chapter12/OrientationBundleEp · EpStrongBundle.morKx_comp`: $T(\psi\varphi) = T\psi \circ T\varphi$ and $\mu(\psi\varphi,\cdot) = \mu(\psi,\cdot) \circ \mu(\varphi,\cdot)$. The proof works on the open set $s(\text{sheet}\,\varphi) \cap s(\text{sheet}\,\psi\varphi) \cap \widehat{\varphi}^{-1}(s(\text{sheet}\,\psi))$ around x `Chapter12/OrientationBundleEp · EpStrongBundle.compSet`: there the isomorphisms of φ, ψ compose to that of $\psi\varphi$ as germs, and `morT_comp` applies. - *Units* `Chapter12/OrientationBundleEp · EpStrongBundle.morTx_unit` `Chapter12/OrientationBundleEp · EpStrongBundle.morKx_unit`: $T(1_x) = \text{Id}$, since $1_x \circ 1_x = 1_x$ and composition gives an idempotent invertible map. - *Inverses* `Chapter12/OrientationBundleEp · EpStrongBundle.morTx_inv` `Chapter12/OrientationBundleEp · EpStrongBundle.morKx_inv`: $T(\varphi^{-1}) \circ T\varphi = \text{Id}$, from composition and units; so $T(\varphi^{-1}) = (T\varphi)^{-1}$ `Chapter12/OrientationBundleEp · EpStrongBundle.morTx_inv_eq_symm` `Chapter12/OrientationBundleEp · EpStrongBundle.morKx_inv_eq_symm`.

The action on linearizations `Chapter12/OrientationBundleEp · EpStrongBundle.linMor`: $\varphi_*S = \mu(\varphi,\cdot) \circ S \circ (T\varphi)^{-1}$ (p. 592), read in the chosen chart points `Chapter12/OrientationBundleEp · EpStrongBundle.linMor_apply`.

Lemma 12.5.1 (explicit), p. 592. Let f be an sc-Fredholm section functor and assume §12.5's standing hypothesis that sc$^+$-sections pass through every smooth fibre point (`hsec`).

(1) `Chapter12/OrientationBundleEp · EpStrongBundle.lemma_12_5_1_one`: for $\varphi : x \to x'$ between smooth objects and $S \in \text{Lin}(f,x)$, $\varphi_*S \in \text{Lin}(f,x')$. *Proof.* Read in the chosen chart point at x', φ_*S is the transfer of S read in the chart point carried along $\text{morIso}(\varphi)$. By `linSet_pullPt_mor`, S read there lies in $\text{Lin}(f,x')$ read there. Part I's transfers map Lin to Lin (Part VI). The conjugate in the other direction, $\mu(\varphi,\cdot)^{-1} \circ S' \circ T\varphi$ for $S' \in \text{Lin}(f,x')$, lies in $\text{Lin}(f,x)$ by the same argument `Chapter12/OrientationBundleEp · EpStrongBundle.morTx_mem`.

(2) `Chapter12/OrientationBundleEp · EpStrongBundle.lemma_12_5_1_two`: $\varphi_* : \text{Lin}(f,x) \to \text{Lin}(f,x')$ is a bijection. *Proof.* Injective, as conjugation by two isomorphisms `Chapter12/OrientationBundleEp · EpStrongBundle.linMor_injective`; surjective by the converse membership of (1). The text derives (2) from (1) and (3) (apply (1) to φ^{-1} and compose); the formal proof gives it directly.

(3) `Chapter12/OrientationBundleEp · EpStrongBundle.lemma_12_5_1_three_unit` `Chapter12/OrientationBundleEp · EpStrongBundle.lemma_12_5_1_three_comp`: $(1_x)_* = \text{Id}$ and $(\psi\varphi)_* = \psi_* \circ \varphi_*$, from the unit and composition laws of T and $\mu(\cdot,\cdot)$ in chart points.

Explicit: the hypothesis `hsec` is not stated in the text; it is Part I's standing hypothesis for $\text{Lin}(f,x) \neq \emptyset$, which §12.5 uses through Part I's Lin, and bump functions on the objects give it. The text calls the lemma obvious; the formal proof is about 1,100 lines, most of it the chart-point comparisons of §XII.16.

On orientations (p. 593). $\varphi_* : \mathrm{Or}_x^f \to \mathrm{Or}_{x'}^f$ sends an orientation o of $\mathrm{DET}(f,x)$ to the orientation whose value on $\varphi_* S$ is the conjugate of $o(S)$ by $T\varphi$ and $\mu(\varphi,\cdot)$ `Chapter12/OrientationBundleEp · EpStrongBundle.orMor` `Chapter12/OrientationBundleEp · EpStrongBundle.orMor_apply`: conjugation by isomorphisms maps the kernel and cokernel of S to those of $\varphi_* S$, hence determinant lines to determinant lines (Part I's `LineOrientation.conj`), compatibly with the identifications along Lin. It is functorial: $(\psi\varphi)_* = \psi_*\varphi_*$ `Chapter12/OrientationBundleEp · EpStrongBundle.orMor_comp`, $(1_x)_* = \mathrm{Id}$ `Chapter12/OrientationBundleEp · EpStrongBundle.orMor_unit`, $(\varphi^{-1})_* = (\varphi_*)^{-1}$ `Chapter12/OrientationBundleEp · EpStrongBundle.orMor_inv`.

XII.18 Definition 12.5.2 (2017: 12.11): the orientation bundle and the orbit spaces

Definition 12.5.2 (restated) `Chapter12/OrientationOrbit · EpStrongBundle.definition_12_5_2`, pp. 593–594. The text defines O_f as the set of pairs (x,o), x a smooth object and $o \in \mathrm{Or}_x^f$, with the projection $\sigma : O_f \to X_\infty$. The formalization takes Part I's orientation space of f as a section of the object bundle, `OrSpace` (Part VI), which is this set. Under the standing hypothesis, σ is surjective with exactly two points over each x `Chapter12/OrientationOrbit · orProj_two`, the given orientation and the other `Chapter12/OrientationOrbit · exists_other_or`, since $\mathrm{Lin}(f,x) \neq \emptyset$ and a real line has two orientations. Part I's topology on O_f (the one of Theorem 6.6.17, Part VI) is the one the text then characterizes in Theorem 12.5.3.

The orbit spaces. The text uses $|X_\infty|$ and $|O_f|$ in Proposition 12.5.6 and Theorem 12.5.7 without defining them. The formalization defines: - the relation on smooth objects "joined by a morphism" `Chapter12/OrientationOrbit · EpGroupoid.SmoothRel`, an equivalence `Chapter12/OrientationOrbit · EpGroupoid.smoothRel_equivalence`, with quotient $|X_\infty|$; smooth points go to smooth points under morphisms, because s and t are local sc-diffeomorphisms; - the relation on O_f: $(x,o) \sim (x',o')$ if some $\varphi : x \to x'$ has $\varphi_* o = o'$ `Chapter12/OrientationOrbit · EpStrongBundle.OrRel`, an equivalence `Chapter12/OrientationOrbit · EpStrongBundle.orRel_equivalence` by the functoriality of φ_* (units, inverses, composition), with quotient $|O_f|$; - the projection $|\sigma| : |O_f| \to |X_\infty|$, $|(x,o)| \mapsto |x|$ `Chapter12/OrientationOrbit · EpStrongBundle.orbitProj`, well defined because related pairs have related base points.

X_∞ carries the topology of Part I's Theorem 2.3.10 (Part II), O_f Part I's topology, and the orbit spaces the quotient topologies.

XII.19 Theorem 12.5.3 (2017: 12.11): the topology of O_f, and morphisms keep orientations continuous

Theorem 12.5.3 (narrower), p. 594. The text: for an sc-Fredholm section functor f over a tame ep-groupoid, O_f has exactly one topology for which it is Hausdorff, $\sigma : O_f \to X_\infty$ is a local homeomorphism, there are exactly two continuous sections near each point, and they propagate as in Part I; and for a morphism $\varphi : x \to x'$ with lift $\hat{\Phi}$, a continuous local section of σ near x is carried by $\hat{\Phi}$ to a continuous local section near x'. The formalization proves the two halves separately.

The topology

The topological part `Chapter12/OrientationOrbit · EpStrongBundle.theorem_12_5_3_hyp`: for X tame, bump functions on the object M-polyfold and tame germ data for f (`IsScFredholmSectionTame`), there is exactly

one topology on O_f with the properties of Part I's Theorem 6.6.17 (`IsOrientationTopology`), and every fibre of σ has exactly two points. *Proof.* Part I's Theorem 6.6.17 `Chapter6/OrientationMainClean · theorem_6_6_17` applied to f as a section of the object bundle, and the two-point fibres of §XII.18 with the standing hypothesis, which bump functions give. The morphisms play no role in this half: the topology of O_f is Part I's. The Lean statement takes Part I's paracompactness instances for the products $\mathbb{R}^n \times X$ and the pull-back bundles, which hold for metrizable spaces and are discharged inside the statement (`paracompactSpace_rn_prod`, `paracompactSpace_rn_pullback`).

Narrower, by the hypotheses inherited from Theorem 6.6.17: the text assumes only a tame X, and Theorem 6.6.17 needs bump functions and tame germ data (gap G.140). The fibre bijections φ_* and their functoriality, which the text recalls in the statement, are §XII.17.

The last sentence

The last sentence is proved in four layers: Part I's push-forward of orientations carried along a local isomorphism in one chart; locality of continuity; the commutation of the transport with a local isomorphism along short paths and then all paths; and the specialization to the isomorphism of a morphism.

Part I's transport, recalled. Part I propagates orientations of f along sc-smooth paths $\gamma : [0,1] \to X$ (Theorem 6.6.13, Part VI): in one chart, the linearizations along the path are stabilized by an sc$^+$-section S of the pull-back bundle over $\mathbb{R}\times$ (the path's parameter space), so that the stabilized kernels form a vector bundle over $[0,1]$; an orientation at $\gamma(0)$ is moved along this bundle to $\gamma(1)$ (a *push-forward*, `IsPush`). The local transport is defined by property (□): along short paths it is a push-forward in one chart (`orLocalTransport_transport_eq`), and along any path the composite over dyadic pieces. An orientation section o over an open U is *continuous* (`IsContOrOn`) if for every sc-smooth path in U between smooth points, the transport carries o at the start to o at the end.

Layer 1: push-forwards carried along a local isomorphism. Let L be a local strong bundle isomorphism from $Y \to U$ to $Y' \to U'$ over ϕ, with $f = \Psi \circ f' \circ \phi$ on U. Each ingredient of a push-forward of f' along $\phi \circ \gamma$ in a chart c of Y' is carried to the transported chart c_T of Y along γ.

- *The stabilizing section* `Chapter12/SectionPull · StrongBundle.LocalIso.exists_pullSection`: an sc$^+$-section S' of the pull-back of Y' gives an sc$^+$-section S of the pull-back of Y whose principal part in c_T is $\beta \cdot S'$ read in c, for a cut-off β supported in the domain of c_T. The cut-off is needed because S' composed with L is defined only over the image of the chart, and an sc$^+$-section must be global. The products with the chart domain are read through the transported chart `Chapter12/SectionPull · StrongBundle.LocalIso.ofProd_transportChart_0` `Chapter12/SectionPull · StrongBundle.LocalIso.Kg_ofProd_transportChart`.
- *Principal parts* `Chapter12/StabilizedKernelPull · StrongBundle.LocalIso.principal_transportChart_eq`: where $\beta = 1$, the principal part of f in c_T is that of f' in c, and also for $f + S$ and $f' + S'$ `Chapter12/StabilizedKernelPull · StrongBundle.LocalIso.principal_transportChart_sectionAdd`; so are the linearizations `Chapter12/StabilizedKernelPull · StrongBundle.LocalIso.linAt_transportChart_sectionAdd`.
- *Stabilized kernels* `Chapter12/StabilizedKernelPull · StrongBundle.LocalIso.isStabKernels_mpull`: if (f', S', s') stabilizes along $\phi \circ \gamma$ in c, the carried data stabilize along γ in c_T; the kernels are the same subspaces of the same model.
- *Orientations* `Chapter12/StabilizedKernelPull · StrongBundle.LocalIso.morPull_apply`: the carried chart points of §XII.16 act on orientations by conjugation; they map the orientation rays of the stabilized kernels to each other `Chapter12/StabilizedKernelPull · StrongBundle.LocalIso.orRay_mpull`, and commute with Part I's push-forward `Chapter12/StabilizedKernelPull · StrongBundle.LocalIso.push_mpull`: pushing

forward and then carrying is carrying and then pushing forward. Conjugation by identities fixes line orientations `Chapter12/StabilizedKernelPull · LineOrientation.conj_refl_apply`.

- *Zeros* `Chapter12/PushDataPull · StrongBundle.LocalIso.isZeroAt_of_transportChart`: zeros of $f' + S'$ at $\phi(x)$ are zeros of $f + S$ at x.

The chart-level statement `Chapter12/PushDataPull · StrongBundle.LocalIso.isPush_mpull`: if e' is a push-forward of f' along $\phi \circ \gamma$ in a chart c_0 of Y' restricted to an open W, then the conjugate of e' by the carried chart points at the two ends is a push-forward of f along γ in the transported chart. The hypotheses are the standing hypothesis for both bundles, $f = \Psi \circ f' \circ \phi$, Part I's paracompactness instances, and proof data: the chart c_0, the open W, a cut-off β equal to 1 on the transported $c_0|W$, and the path γ, parametrized on $[0,1] \subset \mathbb{R}^1$. The proof assembles the five items: the carried section stabilizes, the carried kernels are the stabilized kernels, and the push-forward commutes with the conjugation.

Layer 2: continuity of an orientation is local (extra) `Chapter12/DyadicPathInduction · isContOrOn_of_local_or`. For any of Part I's local transports L and an open U: if every smooth point of U has an open neighbourhood V over which o is continuous, then o is continuous over U. Part I uses this without stating it; it is not immediate, because a path in U need not lie in one V.

Dyadic induction `Chapter12/DyadicPathInduction · scPath_induction_or`. Let Q be a property of paths carried to both halves of a path, and R a property of paths that passes from the two halves to the path. If every point $\gamma(t)$ of a path with Q has an open neighbourhood V such that every sc-smooth path with Q and image in V has R, then every sc-smooth path with Q has R. *Proof.* The preimages $\gamma^{-1}(V_t)$ cover the compact $[0,1]$; take a Lebesgue number λ, and n with $2^{-n} < \lambda$. Every dyadic piece $[k2^{-n}, (k+1)2^{-n}]$ lies in one $\gamma^{-1}(V_t)$, so its reparametrized path has R; induction on n over the halves gives R for γ. *The halves* are reparametrized by the smooth transition function $\chi : \mathbb{R} \to [0,1]$, $\chi(0) = 0$, $\chi(1) = 1$, constant near the ends: $s \mapsto \gamma(\chi(s))$ `Chapter12/DyadicPathInduction · smoothTransPath_or`, sc-smooth `Chapter12/DyadicPathInduction · isScSmoothMap_smoothTransPath_or` and with values in $\gamma([0,1])$ `Chapter12/DyadicPathInduction · smoothTransPath_or_mem`. Part I's transport along a path is the composite of the transports along its two reparametrized halves (`transport_halves`).

Proof of locality. Apply the induction with Q = "lies in U" and R = "the transport carries o from start to end"; R passes from halves to the whole by `transport_halves`, and small paths in a V have R by hypothesis. Continuity passes to open subsets `Chapter12/DyadicPathInduction · IsContOrOn.mono_or` and to sections with the same values `Chapter12/DyadicPathInduction · IsContOrOn.congr_or`.

Layer 3: the transport commutes with a local isomorphism. Let L be as in Layer 1. At a smooth $a \in U$, the orientation map of §XII.16, through a chart point at $\phi(a)$ inside U' (the chosen chart restricted to U' `Chapter12/OrientationLocalCommute · StrongBundle.LocalIso.innerPt`), is a bijection $\mathrm{orxVia}_a : \mathrm{Or}^{f'}_{\phi(a)} \to \mathrm{Or}^{f}_{a}$ `Chapter12/OrientationLocalCommute · StrongBundle.LocalIso.orxVia`, equal to morVia through any chart point inside U' `Chapter12/OrientationLocalCommute · StrongBundle.LocalIso.orxVia_eq_morVia`. An orientation section o' of f' is carried to $a \mapsto \mathrm{orxVia}_a(o'_{\phi(a)})$ on U `Chapter12/OrientationLocalCommute · StrongBundle.LocalIso.pullOrx`. For a path γ in U, $\phi \circ \gamma$ is sc-smooth `Chapter12/OrientationLocalCommute · isScSmoothMap_comp_or`.

On short paths `Chapter12/OrientationLocalCommute · StrongBundle.LocalIso.orxVia_comm_local`: every smooth $a_0 \in U$ has an open $V \ni a_0$ such that for every sc-smooth path γ in U with $\gamma([0,1]) \subset V$, orxVia at the start followed by Part I's transport of f along γ equals the transport of f' along $\phi \circ \gamma$ followed by orxVia at the end. *Proof.* 1. Part I's Theorem 6.6.11 gives a propagation set of f' at $\phi(a_0)$ in a chart c' and one of f at a_0 in a chart c_B: on them, the transport along short paths is a push-forward in that chart (property (□)). 2. Choose V inside both propagation sets (pulled back by ϕ for the first). For γ with image in

V, Part I gives a push-forward e' of f' along $\phi \circ \gamma$ in c', which by (□) represents the transport of f'. 3. Transfer e' to $c'|_{U' \cap W}$, with $W = g^{-1}(N)$ for an open $N \supset \gamma([0,1])$ on which a cut-off β equals 1 (`exists_isScSmoothMap_eq_one_nhdsSet`, from bump functions on the compact image); push-forwards transfer between charts (`IsPush.transfer`). 4. Layer 1 carries it to a push-forward of f along γ in the transported chart; transfer that to c_B, where by (□) it represents the transport of f. 5. The two sides are now composites of orTransfer maps, the conjugation by carried chart points and the two push-forwards; Part I's cocycle identities for orTransfer regroup them (`equiv_comm_square_or`, an identity of composites of bijections `Chapter12/OrientationLocalCommute · equiv_comm_square_or`), and the square commutes.

Along every path in U `Chapter12/OrientationLocalCommute · StrongBundle.LocalIso.orxVia_comm`: dyadic induction with Q = "lies in U" and R = "the square commutes", which passes from halves to the whole because both transports are composites over halves.

Continuity `Chapter12/OrientationLocalCommute · StrongBundle.LocalIso.isContOrOn_pullOrx`: if o' is continuous over an open V', then the carried section is continuous over $U \cap \phi^{-1}(V')$. For a path γ in $U \cap \phi^{-1}(V')$, the commutation turns the transport of the carried section along γ into the transport of o' along $\phi \circ \gamma$, conjugated, and o' propagates along $\phi \circ \gamma$ because it lies in V'. Paths in $U \cap \phi^{-1}(V')$ are first reparametrized by χ, so that all their values (not only those on $[0,1]$) lie in U, as the commutation lemma needs. The converse holds as well `Chapter12/OrientationEquivalenceContinuity · StrongBundle.LocalIso.isContOrOn_of_pullOrx`: if the carried section is continuous over $U \cap \phi^{-1}(V')$, then o' is continuous over $U' \cap V'$, since paths in U' are ϕ of paths in U (ϕ is an sc-diffeomorphism) and the commutation runs backwards.

Layer 4: the morphism. For a morphism σ, $L = \mathrm{morIso}(\sigma)$ maps f to f `Chapter12/OrientationMorphismContinuity · EpStrongBundle.eqOn_morIso_of_functor` (functoriality, §XII.16).

- *The carried value at x'* `Chapter12/OrientationMorphismContinuity · EpStrongBundle.pullOrx_morIso_tgt`: for $\sigma : x \to x'$ and any orientation section o, the section carried by $\mathrm{morIso}(\sigma)$ has the value $\sigma_* o_x$ at x': both are the conjugation by morT and morK of $\mathrm{morIso}(\sigma)$ at x' (`morTx_eq`).
- *The carried value along the sheet* `Chapter12/OrientationGerm · EpStrongBundle.pullOrx_morIso_eq_orMor`: at every y' in $t(\mathrm{sheet})$, the carried value is $\sigma'_* o_{s(\sigma')}$ for the morphism $\sigma' = \tau(y')$ of the sheet ending at y', because the isomorphism of σ and that of σ' have the same germ at y' `Chapter12/OrientationGerm · EpStrongBundle.germEq_morIso_sheet` (the sheet of σ is a sheet through σ', and two sheets through σ' have the same local inverse of t near y') and the germ lemma applies.

Theorem 12.5.3, last sentence (narrower) `Chapter12/OrientationMorphismContinuity · EpStrongBundle.theorem_12_5_3_push`, p. 594. Let X be tame with bump functions on the objects, f an sc-Fredholm section functor with tame germ data, $\sigma : x \to x'$ a morphism between smooth objects, and o an orientation section continuous over an open $V \ni x$ (Part I's `IsContOrOn`). Then the section carried by $\mathrm{morIso}(\sigma)$ is continuous over the open set $t(\mathrm{sheet}) \cap \phi^{-1}(V)$, which contains x', and its value at x' is $\sigma_* o_x$. *Proof.* Continuity is Layer 3 with $L = \mathrm{morIso}(\sigma)$ and $f' = f$ `Chapter12/OrientationMorphismContinuity · EpStrongBundle.theorem_12_5_3_push_hyp`, the form with Part I's paracompactness instances; $x' \in t(\mathrm{sheet})$ and $\phi(x') = x \in V$; the value is the first item of Layer 4. The form without instance arguments discharges them for metrizable spaces. □

Readings. (a) The text's $\hat{\Phi}$ is read as the local strong bundle isomorphism of the sheet of σ (§XII.16), from the target side to the source side; carrying a section from near x to near x' is pulling it back along this isomorphism. (b) "Continuous local section" is read as Part I's continuity of orientations over an open set; its section $y \mapsto (y, o_y)$ is then continuous for Part I's topology (`continuousOn_orSec`), and the converse is §XII.20. *Narrower*: by the hypotheses of Theorem 6.6.17, inherited as in the topological part (G.140),

and the standing hypothesis, which bump functions give.

XII.20 Definition 12.5.4 (2017: 12.12): orientations, and the two readings of continuity

Definition 12.5.4 (same) `Chapter12/OrientationOrbit · EpStrongBundle.definition_12_5_4`, p. 594. Given a topology t on O_f, an *orientation* of f is a section $o : x \mapsto o_x \in \mathrm{Or}_x^f$ over the smooth objects such that $x \mapsto (x, o_x)$ is continuous $X_\infty \to O_f$ for t and $\varphi_* o_{s(\varphi)} = o_{t(\varphi)}$ for every morphism φ between smooth objects. The topology is a parameter; the text's is Part I's, the unique one of Theorem 12.5.3. The second clause alone is *invariance* `Chapter12/OrientationNaturality · EpStrongBundle.IsOrInvariant`, and the definition is continuity and invariance `Chapter12/OrientationNaturality · EpStrongBundle.definition_12_5_4_iff`.

Remark 12.5.5, p. 595, is prose pointing to Chapter 15 (orientations of solution sets) and is not formalized.

The two readings agree (extra). Part I has two notions of a continuous orientation of f over an open set: continuity of $x \mapsto (x, o_x)$ for the topology of O_f (`Continuous (orSec o)`), which is how Definition 12.5.4 says it, and propagation along every sc-smooth path (`IsContOrOn`). Part I proves that the second implies the first (`continuousOn_orSec`), and for Part I's own topology also the converse at points with two orientations (`continuous_orSec_iff` `Chapter6/OrientationBundle · continuous_orSec_iff`). The proofs of §12.5 use the second; the following makes the two interchangeable for every topology with the properties of Theorem 6.6.17.

Agreement is open `Chapter12/ContinuousOrientationSection · isOpen_setOf_orSec_eq`: if $x \mapsto (x, o_x)$ is continuous on $U \cap X_\infty$ and o'' is continuous in Part I's sense over an open $V \supset U$, then the set of smooth points of U where $o = o''$ is open in $U \cap X_\infty$. Indeed, a basic open set of the topology of O_f around (y, o''_y) consists of points (z, o''_z) of the continuous orientation o'', and its preimage under the continuous $z \mapsto (z, o_z)$ is a neighbourhood of y on which $o = o''$.

A continuous section is a continuous orientation `Chapter12/ContinuousOrientationSection · isContOrOn_univ_of_continuous_orSec`: for any local transport of orientations with exactly two orientations at every smooth point, on an M-polyfold whose smooth points have neighbourhoods with preconnected smooth part (`HasConnectedSmoothNbhds`), a section o with $x \mapsto (x, o_x)$ continuous on X_∞ is continuous in Part I's sense over all of X. *Proof.* Near a smooth x, Part I gives a continuous orientation o_1 over some $V \ni x$ with $o_1(x) = o(x)$ (`exists_isContOrOn`); the other orientation o'_1, pointwise the opposite of o_1, is continuous as well. On a neighbourhood $U \subset V$ of x with preconnected smooth part, the sets where $o = o_1$ and where $o = o'_1$ are open by the lemma, disjoint, and cover $U \cap X_\infty$ (two orientations at each point); the first contains x; by preconnectedness, $o = o_1$ on $U \cap X_\infty$. So o is continuous near every smooth point, and locality (Layer 2 of §XII.19) concludes. □ Neither hypothesis restricts: two orientations at every point hold under the standing hypothesis, and every M-polyfold has neighbourhoods with preconnected smooth part `Chapter6/OrientationMainClean · MPolyfold.hasConnectedSmoothNbhds` (Part VI).

The two readings agree (extra) `Chapter12/ContinuousOrientationSection · isContOrOn_univ_iff_continuous`, the form used for Theorem 6.6.17 and Definition 12.5.4: with Part I's hypotheses (tame, bump functions on the objects, tame germ data, sc⁺-sections through smooth points), for every topology t on O_f with the properties of Theorem 6.6.17, $x \mapsto (x, o_x)$ is t-continuous iff o is continuous in Part I's sense over all of X. *Proof.* By the uniqueness in Theorem 6.6.17, t is Part I's topology (`eq_orTopology_of`); then the forward direction is the lemma above and the backward direction is Part I's `continuousOn_orSec`. □ So

Definition 12.5.4 may be read with either notion of continuity, and the statements of §§XII.21–XII.22 are given in the text's.

XII.21 Proposition 12.5.6 (2017: 12.4): orientability through the orbit spaces

Proposition 12.5.6 (narrower), p. 595. The text: f is orientable iff $|\sigma| : |O_f| \to |X_\infty|$ is $(2:1)$ and has a continuous global section.

(□) (same) `Chapter12/OrientationOrbit · EpStrongBundle.proposition_12_5_6_mp`. If o is an orientation in the sense of Definition 12.5.4 (for any topology t on O_f), then $|\sigma|$ is $(2:1)$ `Chapter12/OrientationOrbit · EpStrongBundle.IsTwoToOne` (over every class $|x|$ exactly two classes) and $|x| \mapsto |(x, o_x)|$ is a continuous section of $|\sigma|$. *Proof. Two-to-one.* Over $|x|$ lie $|(x, o_x)|$ and $|(x, \bar{o}_x)|$, $\bar{o}_x$ the other orientation (§XII.18). They differ: if $\varphi : x \to x$ had $\varphi_* o_x = \bar{o}_x$, invariance would give $\varphi_* o_x = o_x$. Any class over $|x|$ is $|(y, \omega)|$ with a morphism $\psi : y \to x$; $\psi_* \omega$ is o_x or $\bar{o}_x$, so the class is one of the two. *The section* is well defined on $|X_\infty|$ because o is invariant, and continuous because $x \mapsto (x, o_x)$ is continuous and the quotient maps are continuous, $|X_\infty|$ carrying the quotient topology.

(□), the invariant lift (narrower) `Chapter12/OrientationOrbit · EpStrongBundle.proposition_12_5_6_mpr_invariant`. If $|\sigma|$ is $(2:1)$, every section s of $|\sigma|$ (continuous or not) lifts to an invariant section o of σ with $|(x, o_x)| = s(|x|)$. *Proof. Existence at each x.* $s(|x|) = |(y, \omega)|$ for some (y, ω) with $|y| = |x|$; a morphism $\varphi : y \to x$ gives $\varphi_* \omega$, with $|(x, \varphi_* \omega)| = s(|x|)$. *Uniqueness at each x.* If two orientations at x have the same class, they are equal `Chapter12/OrientationFromSection · EpStrongBundle.eq_of_quot_eq_of_isTwoToOne`: otherwise the two points of $\sigma^{-1}(x)$ would have the same class, and the fibre of $|\sigma|$ over $|x|$ would have one point. So o_x is determined. *Invariance.* For $\varphi : x \to x'$, $\varphi_* o_x$ has the class of o_x, which is $s(|x|) = s(|x'|)$, so $\varphi_* o_x = o_{x'}$ by uniqueness. □

The rest of (□) is continuity: for Part I's topology on O_f, if s is continuous, then $x \mapsto (x, o_x)$ is continuous.

The isotropy fixes orientations `Chapter12/OrientationFromSection · EpStrongBundle.orMor_isotropy_of_isTwoToOne`: if $|\sigma|$ is $(2:1)$, then $g_* \omega = \omega$ for $g \in G_x$ and $\omega \in \mathrm{Or}^f_x$, since $g_* \omega$ and ω have the same class. And $\sigma_* o_x$ depends only on σ, its source and target being read off it `Chapter12/OrientationFromSection · EpStrongBundle.orMor_eq_of_eq`.

Morphisms near a point fix a continuous orientation `Chapter12/OrientationFromSection · EpStrongBundle.exists_nhds_orMor_eq_hyp`. Let $|\sigma|$ be $(2:1)$ and $\hat{o}$ continuous over an open $U_0 \ni x_0$. There is an open $V \ni x_0$ in U_0 such that every morphism $\varphi : z \to y$ between smooth points of V has $\varphi_* \hat{o}_z = \hat{o}_y$. *Proof.* 1. A natural representation of G_{x_0} on $U(x_0) \subset U_0$ (Theorem 7.1.13): every morphism between points of $U(x_0)$ is $\Gamma(g, z)$ for a unique g, and $\Gamma(g, \cdot)$ is the local inverse of s on a sheet of g near x_0. 2. For each of the finitely many $g \in G_{x_0}$, the last sentence of Theorem 12.5.3 (§XII.19) carries $\hat{o}$ along the sheet of g to a section o^g, continuous over an open $V_g \ni x_0$, with $o^g_{x_0} = g_* \hat{o}_{x_0} = \hat{o}_{x_0}$, by the isotropy fact. 3. o^g and $\hat{o}$ are both continuous near x_0 and agree at x_0; two continuous orientations that agree at a point agree on a neighbourhood with preconnected smooth part (the argument of §XII.20: the agreement set and its complement are both open). Shrink V_g accordingly. 4. Let V be $U(x_0)$ intersected with all V_g and with the points z for which $\Gamma(g, z)$ lies in the sheet of g used in step 2. 5. For $\varphi : z \to y$ between smooth points of V: $\varphi = \Gamma(g, z)$ lies in the sheet of g, so by the second item of Layer 4 (§XII.19) the carried value at y is $\varphi_* \hat{o}_z$; it equals $o^g_y = \hat{o}_y$ by step 3.

Openness `Chapter12/OrientationFromSection · EpStrongBundle.isOpen_orSat_hyp`: for $\hat{o}$ continuous over an open V, the preimage in O_f of $\{|(z, \hat{o}_z)| : z \in V\}$ is open for Part I's topology. It is the set of $(y, \varphi_* \hat{o}_z)$ for morphisms $\varphi : z \to y$ with $z \in V$. Near such a point, the section carried along the sheet of φ is continuous (§XII.19), so its graph over a neighbourhood of y is a basic open set of Part I's topology; its points are $(y', \tau(y')_* \hat{o}_{s(\tau(y'))})$ with $s(\tau(y')) \in V$ near y, again of the given form.

(□) with continuity (narrower) `Chapter12/OrientationFromSection · EpStrongBundle.proposition_12_5_6_mpr_hyp`, p. 595. Let X be tame with bump functions on the objects, f an sc-Fredholm section functor with tame germ data. If $|\sigma|$ is $(2 : 1)$ and has a continuous global section s, for Part I's topology on O_f and the quotient topologies on $|O_f|$ and $|X_\infty|$, then f is orientable: there is an orientation o in the sense of Definition 12.5.4 with $|(x, o_x)| = s(|x|)$.

Proof. Let o be the invariant lift. It remains to show that $x \mapsto (x, o_x)$ is continuous at every smooth x_0. 1. Part I gives a continuous orientation $\hat{o}$ over an open $U_0 \ni x_0$ with $\hat{o}_{x_0} = o_{x_0}$ (`exists_isContOrOn`). 2. The lemma gives $V \ni x_0$ on which morphisms fix $\hat{o}$. 3. The set $A = \{|(z, \hat{o}_z)| : z \in V\}$ is open in $|O_f|$, by openness and the definition of the quotient topology, and contains $s(|x_0|) = |(x_0, o_{x_0})| = |(x_0, \hat{o}_{x_0})|$. 4. By continuity of s and of $X_\infty \to |X_\infty|$, every smooth y near x_0 (inside V) has $s(|y|) \in A$: $s(|y|) = |(w, \hat{o}_w)|$ for some $w \in V$. 5. Since also $s(|y|) = |(y, o_y)|$, some morphism $\varphi : w \to y$ has $\varphi_* \hat{o}_w = o_y$; by step 2, $\varphi_* \hat{o}_w = \hat{o}_y$. So $o_y = \hat{o}_y$ near x_0. 6. $\hat{o}$ is continuous in Part I's sense near x_0, so its section is continuous for Part I's topology (`continuousOn_orSec`), and so is that of o, which agrees with it near x_0. □

The form with Part I's instance arguments `Chapter12/OrientationFromSection · EpStrongBundle.proposition_12_5_6_mpr_hyp'` is the one proved; the form without them discharges the instances for metrizable spaces. *Narrower* only by Part I's hypotheses (G.140). The topology of O_f is Part I's, which Theorem 12.5.3 shows to be the only one with its properties, so the statement is the text's under those hypotheses.

XII.22 Theorem 12.5.7 (2017: 12.12): naturality of the orientation bundle

The setting. A generalized strong bundle isomorphism between strong bundles $W \to X$ and $W' \to X'$ over ep-groupoids is represented by a diagram $W \xleftarrow{\Phi_1} V \xrightarrow{\Phi_2} W'$ of strong bundle equivalences (Definition 10.4.1, Part X) over $\phi_1 : X'' \to X$, $\phi_2 : X'' \to X'$, together with sc-Fredholm section functors f, f', f'' with $f'' = \Phi_1^* f = \Phi_2^* f'$. The text writes f' as the push-forward of f; any f' with the same pull-back serves, and the push-forward is one `Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.pullback_pushforward_witness`: for every sc-Fredholm section functor f of W' and equivalence Φ, $\Phi^* f$ and f satisfy the hypothesis, and $\Phi^* f$ is sc-Fredholm (Theorem 10.4.5 `Chapter10/FredholmEquivalence · theorem_10_4_5_fred`).

Theorem 12.5.7 (narrower), pp. 595–597. (1) There is a homeomorphism $|O_f| \to |O_{f'}|$ covering the homeomorphism $|X_\infty| \to |X'_\infty|$ induced by the diagram. (2) An orientation o of f determines a unique orientation o' of f' corresponding to it over V. The text proves (1) and (2) for one representative and leaves to the reader that the maps do not depend on the representative and are functorial.

One equivalence

Let $\Phi : W \to W'$ be a strong bundle equivalence over $\phi : X \to X'$, with $f = \Phi^* f'$.

The local isomorphisms Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.locIso. By Definition 10.4.1 (2), every object a has an open $U(a) \ni a$ Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.locSet such that ϕ maps it sc-diffeomorphically onto an open $U'(a)$ Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.locSet' and Φ is a strong bundle isomorphism over it: a local strong bundle isomorphism $W|U(a) \to W'|U'(a)$ with base map ϕ and bundle map Φ. a is smooth iff $\phi(a)$ is Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.smooth_obj Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.smooth_of_obj. Near a, $f = \Psi \circ f' \circ \phi$ Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.eqOn_locIso Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.eqOn_loc, which is the pull-back formula.

The orientation bijection Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.orEqv. With the chosen chart point at $\phi(a)$ restricted to $U'(a)$ Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.locPt, the maps $T_{\phi(a)}X' \to T_aX$ and $W'_{\phi(a)} \to W_a$ of Φ^{-1}, read in the chosen chart points Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.eT Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.eK, are mmorT, mmorK of the local isomorphism Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.eT_eq Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.eK_eq. $\mathrm{Lin}(f, a)$ read in the carried chart point is $\mathrm{Lin}(f', \phi(a))$ Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.linSet_loc (§XII.16, `linSet_mpullPt`), and conjugation by eT, eK is a bijection $\mathrm{orEqv}_a : \mathrm{Or}^{f'}_{\phi(a)} \to \mathrm{Or}^{f}_{a}$ Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.orEqv_apply.

Naturality Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.orMor_orEqv: for a morphism $\alpha : a \to b$ between smooth objects, $\alpha_* \circ \mathrm{orEqv}_a = \mathrm{orEqv}_b \circ \phi(\alpha)_*$. *Proof.* (a) The composites $\Phi \circ \mathrm{morIso}(\alpha)$ and $\mathrm{morIso}(\phi(\alpha)) \circ \Phi$ agree near b Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.germAgree₄_mor: on the base because ϕ maps the sheet of α into the sheet of $\phi(\alpha)$ near α (ϕ is a functor and continuous on morphisms), on the bundle because $\Phi(\mu(\gamma, w)) = \mu'(\phi(\gamma), \Phi(w))$. (b) On the set of points where all these isomorphisms are defined Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.natSet, the four-term germ lemma of §XII.16 gives $T\alpha \circ \mathrm{eT}_a = \mathrm{eT}_b \circ T(\phi(\alpha))$ and its fibre form Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.morTx_eT Chapter12/OrientationEquivalenceStep · EpStrongBundle.IsStrongBundleEquivalence.morKx_eK. (c) Conjugations compose. The text calls these the canonical lifts (p. 597).

The orbit maps. ϕ on smooth objects induces $|\phi| : |X_\infty| \to |X'_\infty|$ (`smoothOrbitMap`), a bijection Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.smoothOrbitMap_bijective: surjective because an equivalence is essentially surjective and every smooth x' is isomorphic to $\phi(a)$ for a smooth a; injective because it is fully faithful. The map $(a, o) \mapsto (\phi(a), \mathrm{orEqv}_a^{-1} o)$ of $O_f \to O_{f'}$ (`orSpaceMap`) preserves the orbit relation, by naturality (`orRel_orSpaceMap`), and induces $|\Phi|_* : |O_f| \to |O_{f'}|$ (`orbitOrMap`), a bijection Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.orbitOrMap_bijective over $|\phi|$: $|\sigma'| \circ |\Phi|_* = |\phi| \circ |\sigma|$ Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.orbitProj_orbitOrMap.

Pull-back and push-forward of orientations. *Pull-back* (`pullOr`): $a \mapsto \mathrm{orEqv}_a(o'_{\phi(a)})$; it is invariant when o' is Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.isOrInvariant_pullOr, by naturality (and its inverse form, `orMor_orEqv_symm`). *Push-forward* Chap-

ter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.pushOr of an invariant o: at a smooth x', choose a smooth a and a morphism $\psi : \phi(a) \to x'$, and put $o'_{x'} = \psi_* \mathrm{orEqv}_a^{-1}(o_a)$. It does not depend on the choice Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.pushOr_eq: for two choices (a,ψ), (b,ψ'), $\psi'^{-1}\psi : \phi(a) \to \phi(b)$ is $\phi(\beta)$ for a unique $\beta : a \to b$ (full faithfulness), and $\beta_* o_a = o_b$ with naturality give the same value. At $\phi(a)$ it is $\mathrm{orEqv}_a^{-1}(o_a)$ Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.pushOr_obj, it is invariant Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.isOrInvariant_pushOr, it is the only invariant section corresponding to o at the points $\phi(a)$ Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.pushOr_unique (an invariant section is determined by its values at one point of each orbit), and pull-back undoes it Chapter12/OrientationNaturality · EpStrongBundle.IsStrongBundleEquivalence.pullOr_pushOr.

Continuity of pull-back and push-forward. By the germ lemma, orEqv_b is the orientation map of the local isomorphism at any a with $b \in U(a)$ Chapter12/OrientationGerm · EpStrongBundle.IsStrongBundleEquivalence.orEqv_eq_orxVia, since the local isomorphisms at a and at b have the same germ at b (both are ϕ and Φ) Chapter12/OrientationGerm · EpStrongBundle.IsStrongBundleEquivalence.germEq_locIso. So the pull-back of orientations is, on $U(a)$, the section carried by the local isomorphism at a (Layer 3 of §XII.19) Chapter12/OrientationEquivalenceContinuity · EpStrongBundle.IsStrongBundleEquivalence.pullOr_eq_pullOrx. - *Pull-back* Chapter12/OrientationEquivalenceContinuity · EpStrongBundle.IsStrongBundleEquivalence.isContOrOn_pullOr_hyp: if o' is continuous over an open V', then $\mathrm{pullOr}(o')$ is continuous over $\phi^{-1}(V')$: near each a by Layer 3, and locality joins the neighbourhoods. - *Push-forward* Chapter12/OrientationEquivalenceContinuity · EpStrongBundle.IsStrongBundleEquivalence.isContOrOn_pushOr_hyp: if o is invariant and continuous over all of X, then $\mathrm{pushOr}(o)$ is continuous over all of X'. Near a point $\phi(a)$: the pull-back of $\mathrm{pushOr}(o)$ is o, continuous, so $\mathrm{pushOr}(o)$ is continuous over $U'(a)$ by the converse of Layer 3's continuity Chapter12/OrientationEquivalenceContinuity · StrongBundle.LocalIso.isContOrOn_of_pullOrx: a section is continuous where the section it carries is, since an sc-smooth path in U' is the image under ϕ of its pull-back by the inverse of ϕ, and the commutation of Layer 3 applies to that pull-back. Near an arbitrary x': choose $\psi : \phi(a) \to x'$; the last sentence of Theorem 12.5.3 carries $\mathrm{pushOr}(o)$, continuous near $\phi(a)$, along the sheet of ψ to a section continuous near x' whose values are $\tau(y')_* \mathrm{pushOr}(o)_{s(\tau(y'))}$ (§XII.19, Layer 4), which are the values of $\mathrm{pushOr}(o)$ by invariance. Locality concludes.

The homeomorphisms of one equivalence. Topologies: Part I's on O_f and $O_{f'}$, Theorem 2.3.10's on X_∞, quotient topologies on the orbit spaces. - *A Part I fact* (extra) Chapter5/SmoothLevelContinuity · MPolyfold.IsScSmoothOn.continuousOn_level_comp Chapter5/SmoothLevelContinuity · MPolyfold.IsScSmoothOn.continuousOn_smoothLevel Chapter5/SmoothLevelContinuity · MPolyfold.IsScSmoothMap.continuous_smoothLevel: an sc-smooth map is continuous on every level X_m and on X_∞; the text uses it without comment. *Proof.* A chart is continuous on level m near every point of its domain Chapter5/SmoothLevelContinuity · MPolyfold.continuousAt_levelLift (the generating sets of the topology of X_m are chart preimages); in charts, $\psi \circ f \circ \varphi^{-1}$ is sc^0, hence continuous on level m; so f lifted to level m is continuous near every point; and X_∞ carries the initial topology of the levels. - *The smooth levels of a local sc-diffeomorphism* Chapter12/OrientationOrbitHomeo · MPolyfold.IsScDiffeoOn.smoothFwd Chapter12/OrientationOrbitHomeo · MPolyfold.IsScDiffeoOn.smoothBwd: for an sc-diffeomorphism $U \to U'$, the maps $U_\infty \to U'_\infty$ and back (extended by constants outside), continuous on the smooth parts of U, U' by the Part I fact; so the image of an open subset of U_∞ is open in X'_∞. - *ϕ on X_∞* is continuous and open Chapter12/OrientationOrbitHomeo · EpStrongBundle.IsStrongBundleEquivalence.continuous_smoothMap Chapter12/OrientationOrbitHomeo · EpStrongBundle.IsStrongBundleEquivalence.isOpenMap_smoothMap: on $U(a)_\infty$ it is the forward map of the local sc-diffeomorphism. - *The map of orientation spaces* is continuous and open

Chapter12/OrientationOrbitHomeo · EpStrongBundle.IsStrongBundleEquivalence.continuous_orSpaceMap Chapter12/OrientationOrbitHomeo · EpStrongBundle.IsStrongBundleEquivalence.isOpenMap_orSpaceMap. A basic open set of Part I's topology is the graph of a continuous local orientation over an open set. On the graph of a pulled-back continuous orientation, $(a, o) \mapsto (\phi(a), \mathrm{orEqv}_a^{-1} o)$ is $y \mapsto (\phi(y), o'_{\phi(y)})$ (`orSpaceMap_orSec_pullOr`); preimages and images of graphs are graphs of continuous orientations by the continuity of pull-back, and of the carried sections of Layer 3. - *Open orbit maps.* The saturation of an open subset of O_f is open Chapter12/OrientationOrbitHomeo · EpStrongBundle.isOpen_orSat: near a point $(y_0, \varphi_*\omega)$ with (x, ω) in the open set S, the continuous orientation through (x, ω) whose graph lies in S is carried along the sheet of φ (Theorem 12.5.3, last sentence) to one through $(y_0, \varphi_*\omega)$, whose graph lies in the saturation (`orMor_tgtInv_eq_pullOrx`). So $O_f \to |O_f|$ is open Chapter12/OrientationOrbitHomeo · EpStrongBundle.isOpenMap_quotMk_or; likewise $X_\infty \to |X_\infty|$ Chapter12/OrientationOrbitHomeo · EpGroupoid.isOpenMap_quotMk_smooth, since near $t(\varphi)$ the map $y \mapsto s(\tau(y))$ is continuous on the smooth level. - *Homeomorphisms* Chapter12/OrientationOrbitHomeo · EpStrongBundle.IsStrongBundleEquivalence.orbitOrHomeo Chapter12/OrientationOrbitHomeo · EpStrongBundle.IsStrongBundleEquivalence.smoothOrbitHomeo: a bijection of quotients induced by a continuous open map between spaces whose quotient maps are open is continuous and open, hence a homeomorphism.

The diagram

Without topology. *(1)* Chapter12/OrientationNaturality · theorem_12_5_7_one_hyp: for the diagram, $F = |\Phi_2|_* \circ |\Phi_1|_*^{-1} : |O_f| \to |O_{f'}|$ and $G = |\phi_2| \circ |\phi_1|^{-1}$ are bijections with $|\sigma'| \circ F = G \circ |\sigma|$. *(2)* Chapter12/OrientationNaturality · theorem_12_5_7_two_invariant: an invariant section o of σ has exactly one invariant section o' of σ' with $\mathrm{orEqv}_v^{(2)}(o'_{\phi_2(v)}) = \mathrm{orEqv}_v^{(1)}(o_{\phi_1(v)})$ at every smooth object v of V: pull back along Φ_1, push forward along Φ_2, and uniqueness by `pushOr_unique`. These two statements are valid as stated and are the set-level halves of the theorem; the topology is added below.

With Part I's continuity (narrower) Chapter12/OrientationEquivalenceContinuity · theorem_12_5_7_two_hyp: with Part I's hypotheses on the three bases, if o is invariant and continuous over all of X in Part I's sense, then the unique invariant o' of (2) is continuous over all of X': the pull-back along Φ_1 is continuous, and so is its push-forward along Φ_2. The form without instance arguments Chapter12/OrientationEquivalenceContinuity · theorem_12_5_7_two_cont.

Theorem 12.5.7 (1) (narrower) Chapter12/OrientationTransferTheorem · theorem_12_5_7_one_homeo_hyp: with Part I's hypotheses on X, X' and the base of V, there are homeomorphisms $F : |O_f| \to |O_{f'}|$ and $G : |X_\infty| \to |X'_\infty|$ with $|\sigma'| \circ F = G \circ |\sigma|$, and they are the maps of the diagram: $F \circ |\Phi_1|_* = |\Phi_2|_*$, $G \circ |\phi_1| = |\phi_2|$. *Proof.* The homeomorphisms of the two legs, one inverted, composed. The form without instance arguments Chapter12/OrientationTransferTheorem · theorem_12_5_7_one_homeo.

Theorem 12.5.7 (2), as printed (narrower) Chapter12/OrientationTransferTheorem · theorem_12_5_7_two_book_hyp: if o is an orientation of f in the sense of Definition 12.5.4 (continuous section of σ for Part I's topology, invariant), there is exactly one o' that is an orientation of f' in the sense of Definition 12.5.4 and corresponds to o over V. *Proof.* Part I's comparison `continuous_orSec_iff` turns the continuity of Definition 12.5.4 into Part I's continuity over all of X and back, at points with two orientations, which the standing hypothesis gives (§XII.20 proves the same for every topology of Theorem 6.6.17); then the previous statement. The form without instance arguments Chapter12/OrientationTransferTheorem · theorem_12_5_7_two_book.

Narrower, in (1) and (2): by Part I's hypotheses on X, X' and the base of V (tame, bump functions, tame

germ data) and the standing hypothesis, inherited as in Theorem 12.5.3 (G.140); and by being stated for one representative's data, not for Chapter 10's classes (G.192).

Independence of the representative, and functoriality

Both are left to the reader in the text. They are proved for the data of diagrams (equivalences, natural transformations of strong bundle functors, Definition 10.4.8, and section functors on the middles) and need none of Part I's hypotheses, since they are statements about the bijections.

Natural equivalences act through morphisms. Let $\Phi, \Psi : W \to W'$ be strong bundle equivalences over ϕ, ψ with $f = \Phi^* f' = \Psi^* f'$, and $T : \Phi \Rightarrow \Psi$ a natural transformation covering $\tau : \phi \Rightarrow \psi$; its object map is continuous `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.continuous_natApp`. *Germs* `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.germ_nat`: near a, $\mathrm{morIso}(\tau(a)) \circ \Psi = \Phi$ on base and bundle: on the base because $\tau(y)$ lies in the sheet of $\tau(a)$ for y near a, so $s(\tau_{\mathrm{sheet}}^{-1}(\psi(y))) = \phi(y)$; on the bundle because $T(w) = (\tau(P(w)), \Phi(w))$ is a morphism from $\Phi(w)$ to $\Psi(w)$, i.e. $\Psi(w) = \mu'(\tau(Pw), \Phi(w))$. On the comparison set `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.natSet'` the germ lemma gives $\mathrm{eT}_\Psi(a) \circ T(\tau(a)) = \mathrm{eT}_\Phi(a)$ and the fibre form `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.eT_nat` `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.eK_nat`, hence `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.orEqv_nat`

$$\mathrm{orEqv}_\Psi(a) \circ \tau(a)_* = \mathrm{orEqv}_\Phi(a).$$

On orbits, (a, o) goes to $(\phi(a), \ldots)$ and $(\psi(a), \ldots)$, related by $\tau(a)$ (`orRel_orSpaceMap_nat`), so $|\Phi|_* = |\Psi|_*$ `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.orbitOrMap_nat` and $|\phi| = |\psi|$ `Chapter12/OrientationEquivalenceNatural · EpStrongBundle.IsStrongBundleEquivalence.smoothOrbitMap_nat`.

Composition. For equivalences $\Phi : W \to W'$ over ϕ and $\Psi : W' \to W''$ over ψ with $f = \Phi^* f'$, $f' = \Psi^* f''$: $f = (\Psi \circ \Phi)^* f''$ `Chapter12/OrientationEquivalenceComp · EpStrongBundle.IsStrongBundleEquivalence.pullback_comp_of` (Proposition 10.4.4). Near a, the local isomorphism of $\Psi \circ \Phi$ is the composite of those of Ψ at $\phi(a)$ and Φ at a (`germ_comp`, on the comparison set `compLocSet`). A three-term form of the transfer lemma `Chapter12/OrientationEquivalenceComp · StrongBundle.LocalIso.transferT_mpullPt₃` `Chapter12/OrientationEquivalenceComp · StrongBundle.LocalIso.transferK_mpullPt₃` (a chart point carried along L then L_2 and one carried along M agree to first order when $L \circ L_2 = M$ near the point) gives $\mathrm{eT}_{\Psi\Phi}(a) = \mathrm{eT}_\Phi(a) \circ \mathrm{eT}_\Psi(\phi a)$ and the fibre form `Chapter12/OrientationEquivalenceComp · EpStrongBundle.IsStrongBundleEquivalence.eT_comp` `Chapter12/OrientationEquivalenceComp · EpStrongBundle.IsStrongBundleEquivalence.eK_comp`, hence $\mathrm{orEqv}_{\Psi\Phi}(a) = \mathrm{orEqv}_\Phi(a) \circ \mathrm{orEqv}_\Psi(\phi a)$ `Chapter12/OrientationEquivalenceComp · EpStrongBundle.IsStrongBundleEquivalence.orEqv_comp`, and on orbits $|\Psi\Phi|_* = |\Psi|_* \circ |\Phi|_*$ `Chapter12/OrientationEquivalenceComp · EpStrongBundle.IsStrongBundleEquivalence.orbitOrMap_comp`, $|\psi\phi| = |\psi| \circ |\phi|$ `Chapter12/OrientationEquivalenceComp · EpStrongBundle.IsStrongBundleEquivalence.smoothOrbitMap_comp`.

Independence of the representative (restated). *Refinement* `Chapter12/OrientationRepresentativeIndep · EpStrongBundle.IsStrongBundleEquivalence.orbitOrMap_refine`: if H is an equivalence and $\Phi \circ H \simeq K$ (a natural equivalence), then $|K|_* = |\Phi|_* \circ |H|_*$, by composition and the natural-equivalence lemma; on bases likewise (`smoothOrbitMap_refine`). So a diagram and its refinement through H (legs $\Phi_1 \circ H \simeq K_1$, $\Phi_2 \circ H \simeq K_2$)

give the same map $|K_2|_* \circ |K_1|_*^{-1} = |\Phi_2|_* \circ |\Phi_1|_*^{-1}$ Chapter12/OrientationRepresentativeIndep · EpStrongBundle.IsStrongBundleEquivalence.theorem_12_5_7_refinement Chapter12/OrientationRepresentativeIndep · EpStrongBundle.IsStrongBundleEquivalence.theorem_12_5_7_refinement_base. Two diagrams with a common refinement, which is the relation `SDiagram.Equiv` of Chapter 10's localization, give the same maps $|O_f| \to |O_{f'}|$ and $|X_\infty| \to |X'_\infty|$ Chapter12/OrientationRepresentativeIndep · EpStrongBundle.IsStrongBundleEquivalence.theorem_12_5_7_rep_indep Chapter12/OrientationRepresentativeIndep · EpStrongBundle.IsStrongBundleEquivalence.theorem_12_5_7_rep_indep_base; the homeomorphisms of (1), having the same underlying maps, agree as well.

Functoriality (restated) Chapter12/OrientationRepresentativeIndep · EpStrongBundle.IsStrongBundleEquivalence.theorem_12_5_7_functorial Chapter12/OrientationRepresentativeIndep · EpStrongBundle.IsStrongBundleEquivalence.theorem_12_5_7_functorial_base: for diagrams $W \leftarrow V_1 \to W'$ and $W' \leftarrow V_2 \to W''$, a middle V_3 with equivalences $\Pi_1 : V_3 \to V_1$, $\Pi_2 : V_3 \to V_2$ and a natural equivalence between the two composites to W' (the shape of Chapter 10's weak fibred product), the map of the composite diagram $W \leftarrow V_3 \to W''$ is the composite of the two maps. *Proof.* Composition turns each leg of the composite into a composite of legs, and the natural equivalence identifies the two routes through W'.

Restated: the independence is stated through refinements and the composite through its data, rather than for Chapter 10's classes `SDiagram`, `GenSBMap` and their composition; feeding those in is gap G.192 (§XII.24).

XII.23 Witnesses and the hypotheses

This section lists, for the whole chapter, every hypothesis that a formal statement carries beyond the text's, whether it is added, made explicit or inherited, and its witness. It also lists the text's hypotheses that the proofs do not use, and a witness for every definition. Degenerate witnesses, those whose boundary data are empty because $\partial X = \emptyset$ or whose construction is solved by its own input, are marked as such, with the non-degenerate case named where one exists.

Hypotheses of §12.2

Theorem 12.2.2 (§XII.3). None added. The paracompactness of $|X|$ is the text's. The good neighbourhood property (5) of Theorem 12.2.6, which the text invokes for the transport, is not used: the transport is well defined by invariance under G_x, two morphisms from y into $U(x)$ differing by a unique element of G_x. Witness: the theorem itself gives an auxiliary norm on every strong bundle over an ep-groupoid with paracompact $|X|$.

Theorem 12.2.7 (§XII.6). None added to the book statement Chapter12/AuxNormLocalExtension · EpStrongBundle.hasLocalExtensions_of_isTame: for every tame X with paracompact $|X|$ an auxiliary norm of $W|\partial X$ has local extensions, and the global part then gives the extension. The global part Chapter12/AuxNormExtension · EpStrongBundle.theorem_12_2_7_hyp takes the local extensions as a hypothesis and needs no tameness; its witness Chapter12/AuxNormExtension · EpStrongBundle.theorem_12_2_7_hyp_witness is degenerate in the second sense: the local extension is the global norm of Theorem 12.2.2 restricted Chapter12/AuxNormExtension · EpStrongBundle.hasLocalExtensions_of_isAuxNorm. The non-degenerate case is the book statement itself, whose local step builds the norm N' from a continuous retraction onto the boundary in a tame chart Chapter12/AuxNormLocalExtension · StrongBundle.exists_localExtension_of_isTame. *Kept and unused.* Tameness in the global part; the local step uses only a tame chart of the base, the fibre formula being evaluated in any strong bundle chart of the atlas.

Theorems 12.2.11 and Remark 12.2.12 (§XII.8). None added. Reflexive fibres and paracompactness of $|X|$ are the text's. Witness: the theorem itself, for every bundle with reflexive fibres and paracompact $|X|$.

Theorem 12.2.13 (§XII.9). None added; the paracompactness of $|X|$ is made explicit. The text's proof takes it from Theorem 12.2.11, and Theorem 12.2.7, of which Theorem 12.2.13 is the reflexive variant, states it. Witness of all hypotheses together `Chapter12/ReflexiveLocalExtension · TrivialBundle.theorem_12_2_13_witness`: degenerate, $\partial X = \emptyset$ for the project's $\mathbb{R}^n$ (`rnPolyfold`, a single chart onto all of $\mathbb{R}^n$), so the boundary norm is empty data. The book statement adds nothing to the text's hypotheses, so the witness serves only as a consistency check; a non-degenerate case would take the quadrant $[0,\infty)\oplus W$ of Proposition 12.3.7's witness, seen as a trivial ep-groupoid, with a reflexive norm over its boundary restricted from one of Theorem 12.2.11. The global part `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.theorem_12_2_13_hyp` takes the reflexive local extensions as a hypothesis; for tame X it is discharged `Chapter12/ReflexiveLocalExtension · EpStrongBundle.hasReflexiveLocalExtensions_of_isTame` `Chapter12/ReflexiveLocalExtension · StrongBundle.exists_reflexiveLocalExtension_of_isTame`. Its witnesses are degenerate: the restriction of a global reflexive norm `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.hasReflexiveLocalExtensions_of_isReflexiveAuxNorm` `Chapter12/ReflexiveAuxNormExtension · EpStrongBundle.theorem_12_2_13_hyp_witness` (the extension is its own input), and the trivial bundle over $\mathbb{R}^n$ `Chapter12/ReflexiveAuxNormExtension · TrivialBundle.epBundle_reflexive_witness` ($\partial X = \emptyset$).

Hypotheses of §12.3

Theorem 12.3.2 and Theorem 12.3.3 (§§XII.10–XII.11). (2) of Theorem 12.3.2 and Theorem 12.3.3 take ep bump functions in the pointwise reading: for every object x and open $U \ni x$, an sc-smooth invariant function supported in the saturation of U and nonzero at x. This is the project's reading of Part I's Definition 5.3.1 (Part V), not an added hypothesis. Witnesses: the trivial ep-groupoid on $\mathbb{R}^n$ `Chapter12/BumpEp · EpGroupoid.admitsBumpFunctionsPointwise_trivial_rn`, and every ep-groupoid whose object M-polyfold admits pointwise bump functions and $|X|$ is paracompact (Theorem 12.3.2 (2) itself). The first is degenerate in a third sense, which does not concern the boundary: its isotropy groups are trivial, so the averaging step of the construction is the identity. The second is the general case. Theorem 12.3.2 (1) is restated as two equivalences, one per reading. *Kept and unused.* Paracompactness of $|X|$ in Theorem 12.3.3, where it is used only through the pointwise bump functions that the hypothesis already provides.

Definition 12.3.6, Proposition 12.3.7 and Corollary 12.3.8 (§XII.12). Corollary 12.3.8 makes explicit two things that the text leaves implicit: the finite group fixes x_0, and "acts with a lift" is a structure, a group action on the retract and a linear lift to the fibres compatible with the bundle structure. Witness of the local bundle action: the trivial action of any finite group. Witness of Definition 12.3.6 and Proposition 12.3.7, non-degenerate `Chapter12/LocalBoundaryExtension · proposition_12_3_7_nonvacuous`: the partial quadrant $[0,\infty)\oplus W$ with the identity strong bundle retraction, the point 0 on the boundary, and a section of the boundary that is sc$^+$ on the face. The zero section gives a witness on every tame retract `Chapter12/LocalBoundaryExtension · isBoundaryScPlusSectionOn_zero`. *Needs less than the text.* Proposition 12.3.7 uses only the face germs at x_0, so the proposition holds for sections that are sc$^+$ on each face near x_0 without a compatibility condition along the corners.

Theorem 12.3.9 (§XII.13). None added. The bump functions on the objects that the proof takes from Theorem 12.3.2 (2) come from the partitions of unity that the theorem assumes. Witness of all hypotheses together `Chapter12/ScPlusExtension · EpStrongBundle.theorem_12_3_9_hypotheses_rn`: degenerate, $\partial X = \emptyset$. With boundary the data are inhabited on every X (the zero section functor of $W|\partial X$), and the local construc-

tion has the non-degenerate witness of Proposition 12.3.7. *Kept and unused.* Paracompactness of $|X|$, since partitions of unity are assumed. The second neighbourhood V' of the text's bound is not needed.

Hypotheses of §12.4

Theorem 12.4.2 (§XII.14). None added. *Kept and unused.* Paracompactness of $|X|$.

Proposition 12.4.5 and Theorem 12.4.6 (§XII.15). None added. *Kept and unused* in the book's forms: reflexive fibres, sc-smoothness of the section functor and the regularizing property in Proposition 12.4.5, which uses only continuity on level 0 and the compactness properties; tameness and paracompactness in Theorem 12.4.6. Witness of Definition 12.4.3: every section functor with Part I's reflexive local compactness property (Definition 5.2.6) on the object bundle, by Proposition 12.4.5.

Hypotheses of §12.5

§12.5 carries two kinds of hypotheses, both inherited from Part I and both part of gap G.140.

Sc⁺-sections through smooth fibre points (`hsec`). Lemma 12.5.1, the action φ_* on orientations, Theorem 12.5.3, Proposition 12.5.6 and Theorem 12.5.7 (for the three bundles of the diagram) assume that for every smooth point w of a fibre over a smooth object there is an sc⁺-section through w. Part I uses this to make $\mathrm{Lin}(f,x)$ nonempty; the text uses $\mathrm{Lin}(f,x)$ without comment. Witness: bump functions on the objects give it `Chapter3/IndexLocallyConstantLocal · MPolyfold.AdmitsBumpFunctions.hasScPlusSectionsThrough`. In the tame case with partitions of unity it would also follow from Theorem 12.3.9, but that adds partitions of unity, which is no improvement.

Part I's hypotheses of Theorem 6.6.17. Theorem 12.5.3, Proposition 12.5.6 (□), the continuity in Theorem 12.5.7 and its homeomorphisms assume, for X (and X' and the base of V in Theorem 12.5.7): X tame, bump functions on the objects, tame germ data for f. These are exactly the hypotheses under which Part I builds the topology of O_f and propagates orientations along paths; the text's §12.5 assumes only a tame X. Witnesses: those of Theorem 6.6.17 in Part VI, with the bump function witness above. Part I's paracompactness instances for its transports hold for metrizable spaces and are discharged inside the forms without instance arguments `Chapter12/OrientationMorphismContinuity · EpStrongBundle.theorem_12_5_3_push` `Chapter12/OrientationFromSection · EpStrongBundle.proposition_12_5_6_mpr_hyp` `Chapter12/OrientationEquivalenceContinuity · theorem_12_5_7_two_hyp`.

Hypotheses of step lemmas, not of book statements. - $f = \Psi \circ f' \circ \phi$ on U: the text's "$\hat{\Phi}$ maps f to f'". It is discharged for the isomorphisms of morphisms by functoriality `Chapter12/OrientationMorphismContinuity · EpStrongBundle.eqOn_morIso_of_functor` and for equivalences by the pull-back formula; in general it holds for f defined by the formula. - The chart, the open set and the cut-off in the comparison of push-forwards (§XII.19, Layer 1): proof data, constructed in Layer 3. - Continuity hypotheses on orientations: satisfiable by Part I's existence of continuous local orientations near every smooth point. - In the comparison of the two readings of continuity (§XII.20), the general form assumes two orientations at every smooth point and neighbourhoods with preconnected smooth part. Both hold in every M-polyfold under §12.5's standing hypothesis `Chapter6/OrientationMainClean · MPolyfold.hasConnectedSmoothNbhds`, so the specialized form `Chapter12/ContinuousOrientationSection · isContOrOn_univ_iff_continuous` has only Part I's hypotheses.

No hypothesis of Chapter 12 quantifies over all charts or all presentations in a way that would make it unsatisfiable. Definition 12.3.6 asks for a property in every tame chart and presentation; the zero section

and the quadrant witness satisfy it.

The independence of the representative and the functoriality of Theorem 12.5.7 need none of these hypotheses: they are statements about the bijections of orbit spaces, proved for the data of the diagrams.

Superseded forms that remain as component statements

Several statements of the formalization are halves of a book statement, valid as stated, used in the proof of the full form, and kept. Each is described once, where it is used: - the global parts of Theorems 12.2.7 and 12.2.13, with the local extensions as a hypothesis (§§XII.6, XII.9); - the topological part of Theorem 12.5.3, without its last sentence `Chapter12/OrientationOrbit · EpStrongBundle.theorem_12_5_3_hyp` (§XII.19); - the invariant lift of Proposition 12.5.6 (□), without continuity (§XII.21); - Theorem 12.5.7 (1) and (2) without topology `Chapter12/OrientationNaturality · theorem_12_5_7_one_hyp`, and (2) with Part I's continuity in place of Definition 12.5.4's (§XII.22).

A witness for every definition

Definition	Witness	Kind
sc-Fredholm section functor (Def 12.1.1)	every Part I sc-Fredholm section of a trivial ep-groupoid	general
auxiliary norm (Def 12.2.1)	Theorem 12.2.2, every bundle with paracompact $\lvert X\rvert$	general
norm over ∂X with local extensions	restriction of a global norm	degenerate (solved by its input); the book form discharges it for tame X
reflexive auxiliary norm (Def 12.2.10)	Theorem 12.2.11	general
mixed convergence (Def 12.2.8)	constant sequences, and sequences converging on level 1	general
ep bump function, pointwise (Def 12.3.1)	trivial ep-groupoid on $\mathbb{R}^n$; Theorem 12.3.2 (2)	trivial isotropy; general
sc$^+$-section over the boundary, local (Def 12.3.6)	quadrant $[0,\infty)\oplus W$	non-degenerate
sc$^+$-section functor of $W\lvert\partial X$ (Def 12.3.6)	the zero section functor	general, data only
local bundle action (Cor 12.3.8)	the trivial action	general
reflexive local compactness (Def 12.4.3)	Part I's Definition 5.2.6 on the object bundle	general
local isomorphism of a morphism	every morphism of an ep-groupoid	general
orientation bundle O_f (Def 12.5.2)	Part I's O_f under `hsec`	general
continuous local orientation	Part I's, near every smooth point (Theorem 6.6.17)	general
germ equality of local isomorphisms	reflexivity	general

Definition	Witness	Kind
equivalence data of Theorem 12.5.7	the identity diagram; `pullback_pushforward_witness`	general

XII.24 What is not formalized

Gap G.140: §12.5 with a tame X only. Theorem 12.5.3 with its last sentence, Proposition 12.5.6 (□) and the continuity and homeomorphisms of Theorem 12.5.7 carry the hypotheses of Part I's Theorem 6.6.17 (bump functions on the objects, tame germ data). Lemma 12.5.1, Proposition 12.5.6 and Theorem 12.5.7 carry the hypothesis that sc⁺-sections pass through smooth fibre points. The text assumes only that X is tame. These hypotheses are inherited from Part I, and Chapter 12 adds nothing to them. Removing them is Part I work: - Part I's propagation of orientations along sc-smooth paths would have to be built without bump functions on the objects; Part I uses them to construct the stabilizing sc⁺-sections of its push-forward. - The tame germ data would have to be derived from the tameness of X and the Fredholm property; Part I takes it as a separate hypothesis. - `hsec` would then follow, in the tame case, from the bump functions or from Theorem 12.3.9 with partitions of unity.

Where the hypotheses enter. `hsec` enters through Part I's $\mathrm{Lin}(f, x)$: without it the set of linearizations at a point may be empty, and the action of a morphism on orientations (§XII.17) is a map between possibly empty sets. Bump functions and tame germ data enter through Part I's Theorem 6.6.17 only: the topology of O_f, the existence of a continuous local orientation through every point of O_f, and the propagation along sc-smooth paths that defines continuity. The germ lemma, Lemma 12.5.1, the invariant lift of Proposition 12.5.6, the set-level halves of Theorem 12.5.7, and the independence and functoriality statements do not use Theorem 6.6.17's hypotheses; they carry only `hsec`, or nothing. So a Part I theorem without these hypotheses would remove them from Theorem 12.5.3, Proposition 12.5.6 (□) and the continuity in Theorem 12.5.7 without changing their proofs.

No line estimate is recorded for G.140. Its size is that of the corresponding Part I work, and Chapter 12's statements would follow from the Part I theorem by dropping the hypotheses, since every proof of §12.5 uses them only through Part I's lemmas.

Gap G.192: Theorem 12.5.7 for Chapter 10's classes of diagrams (`SDiagram`, `GenSBMap`). Everything is proved for the data of the diagrams (§XII.22). Two pieces are missing. - (a) *The restatement for a diagram of Chapter 10*, about 80–150 lines. Both legs are in the class of equivalences; the section functors on the middle are the pull-backs. Chapter 10's equivalence of diagrams, a common refinement with a natural equivalence, is unpacked into the independence statement. The result is a map on generalized strong bundle isomorphisms. - (b) *Chapter 10's composite diagram fed into the functoriality statement*, about 70–150 lines. This needs two facts: the right leg of the composite is an equivalence when the given one is, and the cone of the weak fibred product supplies the natural equivalence of the two composites.

Together about 150–300 lines. Neither part involves orientation theory; both are bookkeeping between Chapter 10's localization and the statements of §XII.22.

What (a) involves, step by step. A generalized strong bundle isomorphism is a class of diagrams under Chapter 10's equivalence. To define the map $|O_f| \to |O_{f'}|$ of a class, one picks a representative diagram, checks that its legs are strong bundle equivalences in the sense used by §XII.22 (the class of equivalences of Chapter 10 is defined through Definition 10.4.1, so this is an unfolding), and takes $|\Phi_2|_* \circ |\Phi_1|_*^{-1}$. The

section functor on the middle is not part of Chapter 10's data; it is $\Phi_1^* f$, and the hypothesis $\Phi_1^* f = \Phi_2^* f'$ is the condition that the class maps f to f'. Two representatives related by Chapter 10's equivalence have a common refinement with natural equivalences on both legs, which is the hypothesis of `theorem_12_5_7_rep_indep`; so the map is well defined on the class. The homeomorphisms of (1) have the same underlying maps, so they too descend. Nothing new is proved in (a); its size comes from unpacking the quotient and the existential data of Chapter 10's relation.

What (b) involves. Chapter 10 composes two classes through the weak fibred product of the two middles over the shared bundle. Its legs are composites of a projection of the weak fibred product with a leg of a given diagram. That the projection is an equivalence when the opposite leg is, is a statement of Chapter 10 about weak fibred products of equivalences, needed here in the strong bundle form. The cone of the weak fibred product supplies the natural equivalence between the two routes to the shared bundle, which is the hypothesis of `theorem_12_5_7_functorial`. With these two facts the composite's map is the composite of the maps, and functoriality on classes follows from (a).

A reading, not formalization work: Theorem 12.3.2 (1) in the printed pairing. Theorem 12.3.2 (1) says that an ep-groupoid admits sc-smooth bump functions iff its object M-polyfold does. With Definition 12.3.1 as printed (functions "not identically" zero) on both sides, and with the pointwise reading on both sides, it is proved (§XII.10). Pairing Definition 12.3.1 as printed for the ep-groupoid with Part I's pointwise bump functions on the objects, its (□) is Part I's open question whether weak bump functions give pointwise ones (Part V). This is a question about the reading of Definition 5.3.1, which Chapter 12 inherits; it needs no Chapter 12 formalization.

Remark 12.5.5 is prose. It comments on the choices behind Definition 12.5.4 and makes no claim that is not formalized elsewhere in §12.5.

No numbered item is unformalized. Every definition, lemma, proposition, theorem, corollary and remark of Chapter 12 has a formal counterpart, as listed in the Map; no statement was found not to hold as we read it.

XII.25 What the formalization taught us

One pattern carries the chapter. Chapter 12 is Part I seen through the morphisms, and most of its formal content is one pattern used again and again: build an object on a neighbourhood $U(x)$ with the natural action of G_x, average it over G_x, transport it to the saturation by a choice of morphisms, and glue with a partition of unity of $|X|$. Norms (Theorems 12.2.2, 12.2.7), reflexive norms (Theorems 12.2.11, 12.2.13), bump functions (Theorem 12.3.2) and sc$^+$-sections (Theorems 12.3.3, 12.3.9, Remark 12.3.5) all follow it. Formalizing the pattern once, as averaging, transport and gluing lemmas with the property to be preserved as a parameter, made each of these theorems a matter of checking that its property survives the three steps.

Invariance, not property (5), makes the transport well defined. The text invokes the good neighbourhood property (5) of Theorem 12.2.6 for the transport. What the proof needs is that the averaged object on $U(x)$ is invariant under G_x: two morphisms from y into $U(x)$ differ by a unique element of G_x, so the transported value does not depend on the choice. Property (5) is proved (§XII.5) but plays no role in the constructions.

The average of a square. The average of a bump function over a finite group can vanish identically: positive and negative values may cancel. The average of its square cannot, since it is nonnegative and

positive where the function is nonzero. The text's functions are nonnegative anyway, so this changes nothing in the text's argument, but the formal construction squares before averaging (§XII.10).

Completeness comes free. Completeness of glued fibre norms is not a separate check. A continuous fibrewise seminorm satisfying condition (2) of an auxiliary norm is squeezed, near every point, between two multiples of the chart norm, so completeness follows (§XII.2). This lemma is Part I's as much as Chapter 12's, and it removes a step from each of the four norm theorems.

Morphisms preserve mixed convergence. For the reflexive variant one fact carries the pattern: morphisms preserve mixed convergence, because they act boundedly on the fibres and continuously on level 0, and a bounded, level-0 convergent sequence in a reflexive fibre is mixed convergent. This is a stronger form of Remark 12.2.9 (§XII.7). With it, averaging, transport and gluing all keep lower semicontinuity. The gluing step needs one more observation: near a point only finitely many terms of the partition of unity matter, and the others are nonnegative.

The inspection. The local step of Theorem 12.2.13, which the text settles by inspection, rests on the same fact used once more inside one chart. The fibre maps $A(u)$ of the retraction are uniformly bounded near a point and continuous on level 0. So $A(u_k)h_k$ is bounded and convergent in F_0, hence weakly convergent in the reflexive F_1, and the norm N' of the local step is lower semicontinuous under mixed convergence (§XII.9).

Inclusion–exclusion uses only the face germs. The inclusion–exclusion formula of Proposition 12.3.7 restricts to s on the boundary because an alternating sum over subsets collapses when one index is already on its face. Written out, the face germs at x_0 are all that is used. So the proposition holds in a stronger form, without compatibility along the corners, and Part I's ∂-extension theorem is assembled from it (Part V).

Less than the tame local model. The local step of Theorem 12.2.7 needs less than the text's tame local model. The retraction onto the boundary is built in a tame chart of the base. The fibre formula can be evaluated in any strong bundle chart of the atlas, since only three properties of the retraction enter: it is continuous, its values lie in ∂X, and it is the identity on ∂X.

Hypotheses that are not used. - Paracompactness of $|X|$ in Theorems 12.3.3, 12.3.9 (where partitions of unity are assumed), 12.4.2 and 12.4.6. - Tameness in the global part of Theorem 12.2.7 and in Theorem 12.4.6. - Reflexivity, sc-smoothness and the regularizing property in Proposition 12.4.5. - The second neighbourhood V' in the bound of Theorem 12.3.9.

Theorem 12.3.9 uses bump functions on the objects, which the text takes from Theorem 12.3.2 (2); they come from the assumed partitions of unity, so no hypothesis is added.

A hypothesis that is used but not printed. Theorem 12.2.13 needs paracompactness of $|X|$. Its proof takes it from Theorem 12.2.11, and Theorem 12.2.7, its non-reflexive counterpart, states it. The formal statement makes it explicit (§XII.9).

The labels of Theorem 12.4.2. The proof of Theorem 12.4.2 labels its three implications in an order that its arguments presumably permute. The formal proof follows the arguments: each implication is proved by the argument that establishes it (§XII.14).

A lifting argument in Proposition 12.4.5. The step (3)$\square$ (1) of Proposition 12.4.5, "easily obtained" in the text, needs a lifting argument through the properness of t. If the classes $\pi(u_k)$ converge to $\pi(q)$ in $|X|$, there are objects v_k in the same classes with $v_k \to q$: along a decreasing neighbourhood basis V_n of q, v_k is chosen in the basic set of the largest index already reached by $\pi(u_k)$, using that π is open.

The properness of t then gives a convergent subsequence of the morphisms $a_k \to v_k$, and with it of the sources (§XII.15).

The obvious lemma. In §12.5 the text's "obvious" Lemma 12.5.1 took about 1,100 lines. A morphism acts on $\mathrm{Lin}(f, x)$ through a local strong bundle isomorphism built from its sheet. Part I's linearizations live in chart points, so they have to be pulled back along it and compared. Theorem 12.5.7 repeats this between two different bundles (§§XII.16–XII.17, XII.22).

Three ingredients of orientation transport. The orientation bundle is Part I's, and Part I's Theorem 6.6.17 supplies its topology. What §12.5 adds is one statement, used three times (Theorem 12.5.3's last sentence, Proposition 12.5.6 (□), Theorem 12.5.7 (2)): Part I's propagation of orientations along paths agrees with the action of local strong bundle isomorphisms. It took about 2,100 lines and three ingredients the text does not mention. 1. *The stabilizing sc⁺-section is carried along.* The stabilizing sc⁺-section of Part I's push-forward must itself be carried along the isomorphism. This needs a cut-off, and then stabilized kernels, orientation rays and push-forwards correspond term by term (§XII.19, Layer 1). 2. *Continuity is local.* Part I never states that continuity of an orientation is a local property. It is, by a dyadic induction on sc-smooth paths with a Lebesgue number of the cover by chart domains, and this locality lemma turns the chart-level comparison into continuity (§XII.19, Layer 2). 3. *The germ lemma.* The orientation map of a local isomorphism depends only on its germ. So the isomorphisms of two sheets through one morphism, or of an equivalence at two nearby objects, act alike. The text uses this silently in passing from one sheet to another (§XII.16).

With these, Proposition 12.5.6 (□) is short. Over a two-to-one $|\sigma|$ the isotropy fixes the orientations, so near a point every morphism maps a continuous local orientation to itself, and the lifted section is that orientation there (§XII.21). What Theorem 12.5.7 needs beyond this is the topology of quotients and the comparison of representatives, not orientation theory.

The connectedness argument. The two readings of continuity of an orientation agree by a connectedness argument (§XII.20). With exactly two orientations at each smooth point, two sets are open: where a continuous section agrees with a continuous orientation, and where it agrees with the opposite one. They are complementary and cover a neighbourhood with connected smooth part, so one of them is all of it.

Levels. The homeomorphism of Theorem 12.5.7 (1) needs one fact that Part I uses without comment: an sc-smooth map is continuous on every level and on X_∞. It also needs the openness of the orbit maps of O_f, which is once more the last sentence of Theorem 12.5.3 (§XII.22).

The natural-equivalence lemma. The independence of the representative and the functoriality, which the text leaves to the reader, rest on one lemma. A natural transformation between two equivalences changes their orientation maps only by the action of morphisms, which the orbit relation identifies. It is the germ lemma applied to the local isomorphism of a morphism (§XII.22).

What Chapter 12 asks of Part I. Beyond the statements of Part I that it restates on the objects, the chapter uses Part I in four places, and each is a point where a Part I lemma had to be stated in a form Part I itself did not need: - the automatic completeness lemma for glued fibre norms (§XII.2), used by every norm theorem; - mixed convergence and its lower semicontinuity in a pointwise ε-form that composes under averaging, transport and gluing (§XII.7); - the ∂-extension of Part I's Definition 5.4.1, assembled from the inclusion–exclusion construction of Proposition 12.3.7 (§XII.12); - Part I's orientation transport, through the comparison with local strong bundle isomorphisms, the locality of continuity, and the level continuity of sc-smooth maps (§§XII.19–XII.22).

Each of these is stated once and used throughout; the chapter's own proofs are the passage through the morphisms.

How the statements depend on each other. The four norm theorems rest on Theorem 12.2.2's construction and the completeness lemma; Theorems 12.2.7 and 12.2.13 add a local step near the boundary, the second under mixed convergence. The bump function theorems feed Theorem 12.3.3 and, through the partitions of unity, Theorem 12.3.9, whose local step is Proposition 12.3.7. The compactness results of §12.4 use only the properness of the morphism maps and Part I's compactness notions. In §12.5, Lemma 12.5.1 and the germ lemma feed Theorem 12.5.3; its last sentence feeds Proposition 12.5.6 (□), the openness of the orbit maps, and the continuity of push-forwards in Theorem 12.5.7; the natural-equivalence lemma and composition feed the independence of the representative and functoriality. No statement of §§12.2–12.4 is used in §12.5 except through Part I, so the open gaps G.140 and G.192 touch §12.5 only.

Equivalent representatives are Chapter 10's. Chapter 10's equivalence of diagrams, a common refinement (`SDiagram.Equiv`), is exactly the notion of equivalent representatives that Theorem 12.5.7 needs. What is left (G.192) is to unpack Chapter 10's classes into the statements of §XII.22.

Part XIII. Sc⁺-multisections (HWZ Chapter 13, §§13.1–13.5)

Chapter 13 (Springer 2021, pp. 599–636; 2017 numbers in parentheses) builds the perturbations used by the Fredholm theory on ep-groupoids. The perturbations are sc⁺-multisections: functors $\Lambda : W \to \mathbb{Q}^+$ on a strong bundle $P : W \to X$ that near every point are given by finitely many sc⁺-sections with rational weights. The chapter has five sections. §13.1 constructs *good systems of neighbourhoods*. In such a system every point x has a neighbourhood $U(x)$ that carries the natural action of the isotropy group G_x. The target map is proper on the morphisms leaving $\mathrm{cl}\,U(x)$. And the morphisms from $U(x)$ to $U(x')$ split into components on which source and target are sc-diffeomorphisms onto their images. The section's statements are Lemma 13.1.1, Definition 13.1.2, Proposition 13.1.3, Definitions 13.1.4 and 13.1.5, Lemma 13.1.6, Theorems 13.1.7 and 13.1.8, and Proposition 13.1.9 (2017: Lemma 13.1, Definition 13.1, Proposition 13.1, Definitions 13.2 and 13.3, Lemma 13.2, Theorems 13.1 and 13.2, Proposition 13.2). §13.2 defines the supports, pointwise norms and triviality of sc⁺-multisections. It also defines symmetric section structures, decorated sc⁺-multisections, and the algebra of sums, scalar multiples, products with functions and locally finite sums: Definitions 13.2.1–13.2.5, Lemma 13.2.6, Definitions 13.2.7–13.2.10, Lemma 13.2.11, Definition 13.2.12 and Lemma 13.2.13 (2017: Definitions 13.4–13.8, Lemma 13.3, Definitions 13.9–13.12, Lemma 13.4, Definition 13.13, Lemma 13.5). §13.3 introduces correspondences between index sets. With them it defines structurable and structured sc⁺-multisections, proves that sums, multiples and locally finite sums of structurable ones are structurable, and introduces the tight structures (Definitions 13.3.1–13.3.11, Proposition 13.3.12, Lemma 13.3.14, Proposition 13.3.15, Definition 13.3.17, Corollary 13.3.18, Proposition 13.3.19; 2017: Definitions 13.14–13.21, Propositions 13.3–13.5, Lemma 13.6, Corollary 13.1). §13.4 moves structured sc⁺-multisections along strong bundle equivalences and proper strong bundle coverings, extends them from an open set that meets every orbit, and defines commensurable sums (Theorems 13.4.1, 13.4.3, 13.4.4, Proposition 13.4.2, Definition 13.4.5; 2017: Theorems 13.3–13.5, Proposition 13.6, Definition 13.22). §13.5 defines atomic sc⁺-multisections, the ones built from a single point. It proves that they are structurable and constructs them from bump functions. It also shows that every structured sc⁺-multisection is a locally finite commensurable sum of atomic ones (Definition 13.5.1, Theorems 13.5.3–13.5.7; 2017: Definition 13.23, Theorems 13.6–13.10).

What is proved, and what is not. Every numbered statement of Chapter 13 is formalized and proved, and no gap of the chapter is open.

§13.1. - Lemma 13.1.1 is proved in a stronger form, without the invariance of V (§XIII.1). - Definition 13.1.2 is restated: "carries the natural G_x-action" is read as an invariant open subset of the domain of a natural representation (§XIII.2). - Proposition 13.1.3 and Definition 13.1.4 hold as printed in that reading

(§XIII.2). - Definition 13.1.5, the natural bi-action, is written as the formula its proofs use, with its action laws and its sc-smoothness. Lemma 13.1.6 is proved in a stronger form (§XIII.3). - Theorem 13.1.7 is proved in two forms. - A stronger form reads properness in X and needs neither Q open nor any condition on the closures of the new neighbourhoods (§XIII.4). - The form as printed reads properness in the full subcategory on the open set Q (§XIII.5). - Theorem 13.1.8 is proved as printed (§XIII.6). - Proposition 13.1.9 is proved in a stronger form, with uniqueness among all maps (§XIII.7).

§13.2. - Definition 13.2.1 is Chapter 11's. - Definitions 13.2.2 and 13.2.4 and the claims after them hold as printed. Definition 13.2.3 is restated as a supremum that is shown to be attained (§XIII.8). - Definition 13.2.5 is restated on the domain of a natural representation. Lemma 13.2.6 is proved as printed. The symmetric structures on neighbourhoods with the natural action, which the later definitions need, are formalized with it (§XIII.9). - Definitions 13.2.7 and 13.2.8 hold as printed (§XIII.10). - Definition 13.2.9 is restated. When the intersection $U'(x) \cap U''(x)$ carries no single natural action for both structures, it is read as a neighbourhood inside it on which the two actions agree. The remark after it, that there are in general no inverses, is proved by an example (§XIII.11). - Definition 13.2.10 and Lemma 13.2.11 are proved as printed (§XIII.12). - Definition 13.2.12 is as printed. Lemma 13.2.13 is restated, the infinite sum being written out (§XIII.13).

§13.3. - The correspondences of Definitions 13.3.1–13.3.4, Example 13.3.3 and Remark 13.3.5 are formalized. Definition 13.3.2 also gets the action laws, which the text does not state (§XIII.14). - Definitions 13.3.6–13.3.11 and Remark 13.3.7 are formalized (§XIII.15). - Proposition 13.3.12 is restated: "we may assume $\mathcal{U}_1 = \mathcal{U}_2$" is carried out (§XIII.16). - Remark 13.3.13 is proved in its positive half; the negative half has no formal statement. Lemma 13.3.14 is as printed (§XIII.16). - The construction before Proposition 13.3.15 is proved in a stronger form, with a compatibility the text does not check (§XIII.17). - Proposition 13.3.15 has bijections in place of equalities of index sets (§XIII.17). - Definition 13.3.17 and Corollary 13.3.18 are as printed (§XIII.17). - Proposition 13.3.19 is restated. It holds as printed for a nonempty family, and for every family once a good system exists. The product of correspondences that the text leaves to the reader is written out (§XIII.18). - Remarks 13.3.9 and 13.3.16 are prose.

§13.4. - Theorem 13.4.1 is proved in a stronger form: the canonical structure is a map of structured classes, independent of all choices (§XIII.19). - Proposition 13.4.2 is restated. The project has no strong bundle over an open sub-ep-groupoid, so "Λ structured on $W|V$" is read as structured data relative to V, and "canonical" as uniqueness among the functors on W that extend Λ (§XIII.21). - Theorem 13.4.3 is proved as printed, without Proposition 13.4.2 (§XIII.22). - Theorem 13.4.4 is proved as printed, with the same canonicity as Theorem 13.4.1 (§XIII.23). - Definition 13.4.5 is formalized, with the well-definedness the text calls evident proved (§XIII.24).

§13.5. - Definition 13.5.1 is restated on the domain of a natural representation, and read also on neighbourhoods with the natural action, an extra (§XIII.25). - Theorem 13.5.3 is narrower by one added hypothesis, that a good system exists. It is necessary, since structurability includes a good system, and paracompactness of $|X|$ supplies it (§XIII.26). - Theorems 13.5.4 and 13.5.6 are narrower only through the pointwise reading of "admits sc-smooth bump functions"; in other respects their conclusions are stronger (§§XIII.27, XIII.29). - Theorem 13.5.5 is narrower by $I \neq \emptyset$, which the printed formula presupposes. Its last clause carries the same good-system hypothesis as Theorem 13.5.3 (§XIII.28). - Theorem 13.5.7 is proved in a stronger form: for every structured lift, with partitions of unity and without the paracompactness of $|X|$ (§XIII.30). - Remark 13.5.2 is prose.

Gaps. The chapter's gaps G.141 (Theorem 13.1.7 as printed), G.142 (decorated sc$^+$-multisections and their algebra), G.143 (no inverses), G.148 (Proposition 13.3.19), G.149 (Theorem 13.5.3 and the last clause of

Theorem 13.5.5) and G.163 (Proposition 13.4.2) are all closed. No statement of Chapter 13 was found that does not hold as we read it.

Four decisions that shape the chapter. 1. *Neighbourhoods with the natural action.* The project's natural representation of G_x (Theorem 7.1.13, Part VII) has a connected domain. The invariant subsets of §13.1 need not be connected. A neighbourhood with the natural action is therefore a natural representation together with an open $U \ni x$ inside its domain, invariant under every $\Phi(g)$ `Chapter13/GoodSystem · EpGroupoid.NatNbhd`. In this reading every claim of §13.1 that an invariant open subset carries the natural action holds as printed, and the good systems of §13.1 are made of such neighbourhoods. Definitions 13.2.5 and 13.5.1, which predate the good systems in the formalization, ask for the connected domain of a natural representation, the reading of Chapter 11. The structures on good systems (§§XIII.9–XIII.10) and the atomic pieces of Theorem 13.5.7 (§XIII.30) are therefore formalized on neighbourhoods with the natural action. 2. *Components named by a point.* A component of $\mathcal{U}(x, x')$ is the connected component in $\mathcal{U}(x, x')$ of one of its morphisms, and it is empty if the morphism is not in $\mathcal{U}(x, x')$. No statement needs a separate index set of components, and many statements need no membership hypothesis. 3. *Multisections as functors, structures as data.* An sc$^+$-multisection is a functor $\Lambda : W \to \mathbb{Q}^+$ satisfying Chapter 11's predicate, with local section structures on open sets `Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsScPlusMultisection` `Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsLocalRepOn`. Decorations, structures and structured tuples are data attached to it. The decorated and structured multisections of the text are quotients of the data by the equivalences of Definitions 13.2.8 and 13.3.8. 4. *Index sets are types.* The text writes equalities of index sets: $I'_x = \{*\}$ and $I'_x = I_x$ in Proposition 13.3.15, $I_x = I'_x$ in Definition 13.3.8, $K_x = \prod_l K^l_x$ in Proposition 13.3.19. The formalization has types with bijections between them, and compares correspondences after relabelling along the bijections. Where the text asks two index sets to be equal (Definitions 13.3.8 and 13.4.5), the formalization asks for an equality of types and compares the correspondences through it.

Hypotheses added, and their witnesses. Each added hypothesis is not derived from the text. - *A good system exists.* Added in Theorem 13.5.3, in the last clause of Theorem 13.5.5, and in Proposition 13.3.19 for the empty family (§§XIII.18, XIII.26, XIII.28). It is necessary. Definition 13.3.6 includes a good system in every structure, so for atomic Λ structurability is equivalent to it. Witnesses: - Theorem 13.1.8 for paracompact $|X|$. - In particular every M-polyfold seen as a trivial ep-groupoid `Chapter13/GoodSystemExistence · EpGroupoid.nonempty_goodSystem_trivial` `Chapter7/EpGroupoid · EpGroupoid.hasParacompactOrbitSpace_trivial`, and the bundles $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ used in Chapter 15 `Chapter15/GeneralPositionAssembly · SBLocalization.nonempty_goodSystem_epSEP_zero`. - A nonempty family in Proposition 13.3.19 needs nothing, since any member's structure carries a good system. - *$I \neq \emptyset$ in Theorem 13.5.5* (§XIII.28). An sc$^+$-multisection has weights summing to 1, and with $I = \emptyset$ the printed formula gives $\Lambda = 0$ over $U(x)$. Witness: the families of Construction I, whose index set is G_x (§XIII.27). - *Pointwise bump functions in Theorems 13.5.4 and 13.5.6* (§§XIII.27, XIII.29). "Admits sc-smooth bump functions" is read as Part XII's pointwise reading of Theorem 12.3.3. Witness: the trivial ep-groupoids $\mathbb{R}^n$ `Chapter12/BumpEp · EpGroupoid.admitsBumpFunctionsPointwise_trivial_rn`. - *$c \neq 0$ and $k \geq 1$ in the example for the remark that there are no inverses* (§XIII.11). These are parameters of an example, not hypotheses of a statement. - *Paracompactness of $|X|$ in the existence of decorations and in the structurability of the zero multisection* (§§XIII.10, XIII.15). This is the text's own setting, through Theorem 13.1.8. Witness: as for good systems.

The hypotheses the text states and the formalization keeps without using: - the properness property in Theorem 13.5.4, and the smoothness of x in its part (2); - bump functions and the smoothness of x in Theorem 13.5.5; - the paracompactness of $|X|$ in Theorems 13.5.6 and 13.5.7.

Map. All files are in `Polyfold/Chapter13/`. They are grouped by topic.

Good systems (§13.1). - `GoodSystem`: neighbourhoods with the natural action and their invariant cores; Lemma 13.1.1; the sets $\mathcal{U}(x, x')$ and their components; Definition 13.1.2, Proposition 13.1.3, Definition 13.1.4; families good on a set. - `BiAction`: the bi-action of Definition 13.1.5 with its laws; the components of a good system; Lemma 13.1.6; stabilizers, D_Σ, the partner homomorphism, Proposition 13.1.9. - `GoodSystemExistence`: transports; Theorem 13.1.7 in the stronger form; Theorem 13.1.8; the witness on trivial ep-groupoids. - `GoodSystemRelative`: the full subcategory on Q, properness relative to Q, properness by ultrafilters, Theorem 13.1.7 as printed.

Sc⁺-multisections as functors (§13.2). - `ScPlusSectionOn`: sc⁺-sections on open sets, through chart representatives; sums, multiples, finite sums and extensions by 0. - `MultisectionSupport`: Definitions 13.2.2–13.2.4 and the claims after them. - `MultisectionSymmetric`: transported sections, equal weights, Definition 13.2.5, Lemma 13.2.6. - `MultisectionConvolution`: the convolution of finitely many functors. - `MultisectionAlgebra`: Definitions 13.2.9 and 13.2.10, Lemma 13.2.11, for functors. - `MultisectionLocallyFinite`: Definition 13.2.12, Lemma 13.2.13.

Decorated sc⁺-multisections (§13.2). - `SymmetricOn`: the relation "same natural action" between neighbourhoods; moving vectors along morphisms; symmetric structures on a neighbourhood with the natural action and their sums, multiples and products. - `DecoratedMultisection`: Definitions 13.2.7 and 13.2.8; Definitions 13.2.9, 13.2.10 and Lemmas 13.2.11, 13.2.13 for decorations and on classes. - `MultisectionNoInverse`: the remark after Definition 13.2.9.

Correspondences and structurable sc⁺-multisections (§13.3). - `Correspondence`: Definitions 13.3.1 and 13.3.2, Example 13.3.3, Remark 13.3.5, products of two correspondences. - `StructurableMultisection`: Definitions 13.3.4, 13.3.6, 13.3.8, 13.3.10, 13.3.11; Proposition 13.3.12; Lemma 13.3.14; the zero multisection as witness. - `TightMultisection`: T_Λ; the construction before Proposition 13.3.15; Proposition 13.3.15, Definition 13.3.17, Corollary 13.3.18. - `PiCorrespondence`: products of families of correspondences; reindexing symmetric structures. - `TightOn`: tight versions over a given adapted good system. - `LocallyFiniteStructurable`: the data of the proof of Proposition 13.3.19, the product structure, Proposition 13.3.19. - `LocallyFiniteSupports`: from locally finite domain supports to Definition 13.2.12; Proposition 13.3.19 with the printed hypothesis.

Pull-backs, push-forwards, extension and commensurable sums (§13.4). - `StrongBundlePullMap`: the common data of a pull-back; equivalences and proper coverings as such data; pulled-back sections. - `MultisectionPullback`: adapted neighbourhoods; the pulled-back structure; canonicity; Theorems 13.4.1 and 13.4.4. - `SymmetricStructurePush`: charts along a morphism; push neighbourhoods; pushed sections and structures. - `MultisectionPushforward`: lifted morphisms; the pushed good system and structure; Theorem 13.4.3; generalized strong bundle isomorphisms. - `StructuredExtensionData`: functors and sc⁺-multisections on $W|V$; structured data on V; the extension functor; unit charts; extension charts. - `StructuredExtension`: the extended structure, Proposition 13.4.2. - `Commensurable`: common data c; count transport along correspondences; Definition 13.4.5 and the locally finite commensurable sum.

Atomic sc⁺-multisections (§13.5). - `AtomicMultisection`: Definition 13.5.1; the multisection of atomic data; its local structure. - `AtomicConstruction`: symmetric families; Theorems 13.5.4, 13.5.5 (existence and uniqueness) and 13.5.6. - `AtomicStructurableLocal`: the local alternative of the proof of Theorem 13.5.3, and the form of Theorems 13.5.3 and 13.5.5 with structurability as a parameter. - `AtomicStructurable`: the data and the structure of the proof of Theorem 13.5.3; Theorem 13.5.3; the last clause of Theorem 13.5.5. - `AtomicSum`: atomic data on a neighbourhood with the natural action; Theorem 13.5.7.

Conventions. Throughout, X is an ep-groupoid with source and target maps s, t, composition $\circ$, inversion $\varphi \mapsto \varphi^{-1}$ and orbit map $\pi : X \to |X|$. The isotropy group G_x is finite (Proposition 7.1.12, Part VII). A natural representation of G_x (Theorem 7.1.13, Part VII) on an open connected $U \ni x$ consists of sc-diffeomorphisms $\Phi(g) : U \to U$ and morphisms $\Gamma(g, z) : z \to \Phi(g)(z)$. Every morphism between two points of U is $\Gamma(g, z)$ for exactly one g. We write $g * z = \Phi(g)(z)$. For $U, U' \subset X$,

$$\mathcal{U}(U, U') = \{\varphi : s(\varphi) \in U,\ t(\varphi) \in U'\}$$

`Chapter13/GoodSystem · EpGroupoid.morBetween`, and $\mathcal{U}(x, x') = \mathcal{U}(U(x), U(x'))$ for a family of neighbourhoods. A subset $A \subset X$ has *proper closure*, or the properness property, if $t : s^{-1}(\mathrm{cl}\, A) \to X$ is proper. From §XIII.8 on, $(P : W \to X, \mu)$ is a strong bundle over X, 0_x the zero of the fibre W_x, and $\Lambda : W \to \mathbb{Q}^+$.

XIII.1 Neighbourhoods with the natural action, and Lemma 13.1.1 (2017: Lemma 13.1)

Definition `Chapter13/GoodSystem · EpGroupoid.NatNbhd`. A *neighbourhood of x with the natural action* is a pair $N = (R, U)$: - R is a natural representation of G_x on the connected open domain U_R, with maps Φ, Γ; - U is an open subset with $x \in U \subset U_R$ and $\Phi(g)(U) \subset U$ for all $g \in G_x$.

All the laws of R restrict to U. On U: - $\Phi(g)$ maps U into U; - $\Gamma(g, z)$ has source z and target $g * z$; - $\Gamma(1, z)$ is the unit; - $\Gamma(gh, z) = \Gamma(g, h * z) \circ \Gamma(h, z)$; - $\Gamma(g^{-1}, g * z) = \Gamma(g, z)^{-1}$; - $\Gamma(\cdot, z)$ is injective in g; - every morphism between two points of U is $\Gamma(g, \cdot)$ for a unique g; - $\pi(g * z) = \pi(z)$.

Reading. The text says "$U(x)$ is G_x-invariant and carries the natural action". The project's natural representations live on connected domains. Proposition 13.1.3 shrinks the neighbourhoods of a good system to arbitrary invariant open subsets, which need not be connected, so the neighbourhood is an invariant open subset of such a domain. Since the domain is open and U lies inside it, the uniqueness clause for morphisms between points of U holds as for the domain itself. Nothing in §13.1 uses connectedness of $U(x)$.

Invariant cores. For a neighbourhood N with the natural action and an open set $V \ni x$, the *invariant core* is

$$U \cap \bigcap_{g \in G_x} \Phi(g)^{-1}(V)$$

`Chapter13/GoodSystem · EpGroupoid.NatNbhd.invariantCore`. It is open because G_x is finite and each $\Phi(g)$ is continuous. It contains x, because $\Phi(g)(x) = x$. It is invariant, because $\Phi(h)$ maps it into itself by the action law $\Phi(g) \circ \Phi(h) = \Phi(gh)$. And it lies in $U \cap V$, taking $g = 1$. So every neighbourhood with the natural action has, inside any open $V \ni x$, a smaller one with the same natural representation `Chapter13/GoodSystem · EpGroupoid.NatNbhd.exists_restrict_subset`. This is the step "we may assume $U(x)$ is invariant" that the text uses throughout.

Existence with the properness property `Chapter13/GoodSystem · EpGroupoid.exists_natNbhd_isProperSubset`. Inside every open $W \ni x$ there is a neighbourhood N of x with the natural action and with $t : s^{-1}(\mathrm{cl}\, U) \to X$ proper. - *Step 1.* Chapter 7 gives, inside any open set around x, an open neighbourhood $U_0 \subset W$ of x that is the domain of a natural representation and whose closure has the properness property (the invariant neighbourhoods of Theorem 7.1.13, Part VII). - *Step 2.* The neighbourhood is that representation

with $U = U_0$. It is invariant because it is the domain.

This is the source of all the neighbourhoods in Chapter 13. Every construction below starts from it and shrinks by invariant cores.

Lemma 13.1.1 (stronger), p. 599 `Chapter13/GoodSystem · EpGroupoid.lemma_13_1_1`. Let N be a neighbourhood of x with the natural action, with $t : s^{-1}(\operatorname{cl} U) \to X$ proper, and let $V \subset U$ be any subset. Then

$$\operatorname{cl}_X V \subset U \iff \operatorname{cl}_{|X|} \pi(V) \subset \pi(U).$$

The text assumes V invariant. The form with that assumption follows at once `Chapter13/GoodSystem · EpGroupoid.lemma_13_1_1_book`. The two directions use different halves of the hypotheses: (□) uses only properness, and (□) uses only the natural action.

Proof of (□). Suppose $\operatorname{cl} V \subset U$. Then $\operatorname{cl} V \subset \operatorname{cl} U$, so $\operatorname{cl} V$ is a closed subset of a set with proper closure. 1. For a closed set A with t proper on $s^{-1}(A)$, the orbit map satisfies $\pi(\operatorname{cl} A) = \operatorname{cl} \pi(A)$ (Proposition 7.1.10, Part VII). 2. Apply this to $\operatorname{cl} V$: $\operatorname{cl}_{|X|} \pi(V) \subset \operatorname{cl}_{|X|} \pi(\operatorname{cl} V) = \pi(\operatorname{cl} V) \subset \pi(U)$.

Proof of (□). Suppose $\operatorname{cl} \pi(V) \subset \pi(U)$, and let $y \in \operatorname{cl} V$. 1. $\pi(y) \in \operatorname{cl} \pi(V) \subset \pi(U)$, so there is a point $z \in U$ and a morphism $\varphi : z \to y$. 2. The target map is a local sc-diffeomorphism, so near φ there is a sheet: a local inverse τ of t on an open $V' \ni y$ with $\tau(y) = \varphi$, continuous, with $t(\tau(y')) = y'$. Set $O = V' \cap \tau^{-1}(s^{-1}(U))$. It is an open neighbourhood of y, since $s(\tau(y)) = z \in U$ and U is open. 3. For $y' \in O \cap V$, $\tau(y')$ is a morphism from $s(\tau(y')) \in U$ to $y' \in V \subset U$. It is therefore $\Gamma(g, s(\tau(y')))$ for a unique g, and $y' = g * s(\tau(y'))$. 4. Since $y \in \operatorname{cl} V$, the filter $\mathcal{N}_V(y)$ of neighbourhoods of y within V is nontrivial, and $O \cap V$ belongs to it. The index g of step 3 takes only finitely many values, since G_x is finite (Proposition 7.1.12, Part VII). So some g_0 occurs frequently along $\mathcal{N}_V(y)$: every neighbourhood of y contains points $y' \in V$ with index g_0. 5. Along these points $y' = \Phi(g_0)(s(\tau(y')))$. As $y' \to y$ along the filter, $s(\tau(y')) \to s(\tau(y)) = z$ by continuity, so the right side tends to $\Phi(g_0)(z)$. By uniqueness of limits in the Hausdorff space X, $y = \Phi(g_0)(z) \in U$, since U is invariant.

Where the formal proof departs from the text. The text takes V invariant and argues with sequences. The formal proof works with filters, and with "occurs frequently" in place of the pigeonhole over a sequence. It never uses that V is invariant: only $V \subset U$ enters, through step 3.

XIII.2 Definition 13.1.2 (2017: Definition 13.1), Proposition 13.1.3 (2017: Proposition 13.1) and Definition 13.1.4 (2017: Definition 13.2)

Components and diffeo-components. For a set S of morphisms and $\varphi \in S$, the component of φ is the connected component of φ in S. For $\varphi \notin S$ it is empty.

A set Σ of morphisms is a *diffeo-component* `Chapter13/GoodSystem · EpGroupoid.IsDiffeoComponent` if $s|_\Sigma$ and $t|_\Sigma$ are sc-diffeomorphisms onto open subsets of the objects.

For an open Σ this is equivalent to s and t being injective on Σ `Chapter13/GoodSystem · EpGroupoid.isDiffeoComponent_iff_injOn`, by the following argument. 1. s and t are local sc-diffeomorphisms (Definition 7.1.1 (1), Part VII). 2. An injective local sc-diffeomorphism on an open set is an sc-diffeomorphism onto its image, which is open `Chapter13/GoodSystem · MPolyfold.IsLocalScDiffeo.isScDiffeoOn_invFunOn`. - The image is open, being a union of the open images of the local sheets. - The inverse is the inverse function on the image. Near each image point it agrees with the inverse of one sheet, by injectivity, so it is sc-smooth

there.

The components of $\mathcal{U}(x,x')$ are open, because $\mathcal{U}(x,x')$ is open (s, t continuous, $U(x)$, $U(x')$ open) and the morphism space is locally connected.

Definition 13.1.2 (restated), p. 600 `Chapter13/GoodSystem · EpGroupoid.GoodSystem`. A *good system of neighbourhoods* is a family $(N(x))_{x\in X}$ of neighbourhoods $U(x)$ with the natural action of G_x (condition (2) of the text) such that: - (1) $t : s^{-1}(\operatorname{cl} U(x)) \to X$ is proper for every x; - (3) for all x, x' and every $\varphi \in \mathcal{U}(x,x')$, the component of φ in $\mathcal{U}(x,x')$ is a diffeo-component.

By the equivalence above, (3) is the injectivity of s and t on every component. The text's "the images are open" is automatic.

On a good system the inverses $(s|_\Sigma)^{-1}$, $(t|_\Sigma)^{-1}$ are functions on the objects (defined arbitrarily off $s(\Sigma)$, resp. $t(\Sigma)$) `Chapter13/GoodSystem · EpGroupoid.GoodSystem.srcInv`. They are sc-smooth on the images. *Restated*: "carries the natural G_x-action" is the reading of §XIII.1, and components are named by a point.

Proposition 13.1.3 (same), p. 600 `Chapter13/GoodSystem · EpGroupoid.proposition_13_1_3`. Let $(U(x))$ be a good system and $\tilde{U}(x) \subset U(x)$ open invariant neighbourhoods of x. Then $(\tilde{U}(x))$ is a good system with the same natural representations `Chapter13/GoodSystem · EpGroupoid.GoodSystem.restrict`.

Proof. 1. *(2).* $\tilde{U}(x)$ is open, contains x, lies in the domain of the representation of $U(x)$, and is invariant. So it is a neighbourhood with the natural action, with the same representation. This is where decision (1) matters: in the reading "the connected domain of a natural representation", $\tilde{U}(x)$ could fail to be such a domain, and the proposition would not hold as we read it. 2. *(1).* $\operatorname{cl}\tilde{U}(x)$ is a closed subset of $\operatorname{cl} U(x)$. A proper map restricted to a closed subset of its domain is proper, so $t : s^{-1}(\operatorname{cl}\tilde{U}(x)) \to X$ is proper. 3. *(3).* $\tilde{\mathcal{U}}(x,x') \subset \mathcal{U}(x,x')$, so the component of φ in the smaller set lies in its component in the larger set, on which s and t are injective. Injectivity passes to subsets, and the smaller component is open, so it is a diffeo-component `Chapter13/GoodSystem · EpGroupoid.GoodSystem.isDiffeoComponent_of_subset`.

The step after the proposition. The text uses the proposition to shrink a good system into given open neighbourhoods $V(x)$. Inside $U(x) \cap V(x)$ the invariant core of §XIII.1 is an invariant open neighbourhood. So every good system has a refinement inside any family of open neighbourhoods `Chapter13/GoodSystem · EpGroupoid.GoodSystem.exists_refinement_subset`.

Definition 13.1.4 (same), p. 600 `Chapter13/GoodSystem · EpGroupoid.GoodSystem.IsRefinement` `Chapter13/GoodSystem · EpGroupoid.GoodSystem.IsSubordinate`. - A good system $\mathcal{W}$ refines $\mathcal{U}$ if $W(x) \subset U(x)$ for all x. - $\mathcal{U}$ is subordinate to an open cover (O_a) if each $U(x)$ lies in some O_a. - The restrictions of Proposition 13.1.3 are refinements `Chapter13/GoodSystem · EpGroupoid.GoodSystem.isRefinement_restrict`.

Families good on a set `Chapter13/GoodSystem · EpGroupoid.IsGoodOn`. Theorems 13.1.7 and 13.1.8 build good systems from partial ones. A family $(N(q))$ of neighbourhoods with the natural action, indexed by all points, is *good on* $Q \subset X$ if for $q, q' \in Q$: - $U(q) \subset Q$; - $t : s^{-1}(\operatorname{cl}_X U(q)) \to X$ is proper; - condition (3) holds on $\mathcal{U}(q,q')$.

Every good system is good on X `Chapter13/GoodSystem · EpGroupoid.GoodSystem.isGoodOn`. A family good on X is a good system. The relation between "good on Q" and the text's good system of the sub-ep-groupoid Q is §XIII.5.

XIII.3 Definition 13.1.5 (2017: Definition 13.3) and Lemma 13.1.6 (2017: Lemma 13.2)

Definition 13.1.5 (restated), p. 601 `Chapter13/BiAction · EpGroupoid.biact`. The text names a map $G_{x'} \times \mathcal{U}(x,x') \times G_x \to \mathcal{U}(x,x')$, $(g',\varphi,g) \mapsto g' * \varphi * g$, "the natural bi-action". The formalization writes the formula that the text's proofs use. For neighbourhoods $N = (R,U)$ at x and $N' = (R',U')$ at x', with $\varphi \in \mathcal{U}(U,U')$:

$$g' * \varphi * g = \Gamma'(g', t(\varphi)) \circ \varphi \circ \Gamma(g, \Phi(g^{-1})(s(\varphi))).$$

- *Source and target.* The source is $\Phi(g^{-1})(s(\varphi))$ `Chapter13/BiAction · EpGroupoid.src_biact` and the target is $\Phi'(g')(t(\varphi))$ `Chapter13/BiAction · EpGroupoid.tgt_biact`. The right factor $\Gamma(g,\cdot)$ is taken at $g^{-1} * s(\varphi)$, so that its target is $s(\varphi)$ and the composite is defined. - *It stays in $\mathcal{U}$.* By invariance of U and U', $g' * \varphi * g \in \mathcal{U}(U,U')$ `Chapter13/BiAction · EpGroupoid.biact_mem`. - *Action laws.* $g' * (h' * \varphi * h) * g = (g'h') * \varphi * (hg)$ `Chapter13/BiAction · EpGroupoid.biact_biact`. Write out both sides and use associativity of composition with $\Gamma'(g'h', z) = \Gamma'(g', h' * z) \circ \Gamma'(h', z)$ on the left and the corresponding identity for Γ on the right. With $1 * \varphi * 1 = \varphi$, from $\Gamma(1,\cdot) = 1$, this is an action of $G_{x'} \times G_x^{\mathrm{op}}$ `Chapter13/BiAction · EpGroupoid.biactMulAction`. - *Cancellations.* $g' * \varphi * g = g' * \psi * g$ implies $\varphi = \psi$, and $g' * \varphi = h' * \varphi$ implies $g' = h'$. The second holds by right cancellation of φ and the injectivity of $\Gamma'(\cdot, t\varphi)$. - *Sc-smoothness* `Chapter13/BiAction · EpGroupoid.isScSmoothOn_biact`. Each $\varphi \mapsto g' * \varphi * g$ is sc-smooth on $\mathcal{U}(U,U')$. - The left action $\varphi \mapsto \Gamma'(g', t\varphi) \circ \varphi$ is sc-smooth because $\Gamma'(g',\cdot)$ is, t is, and composition is sc-smooth on the fibred product. - The right action is reduced to a left action by inversion: $\varphi * g = (g^{-1} * \varphi^{-1})^{-1}$ in the bi-action for $\mathcal{U}(U',U)$. - Inversion is an sc-diffeomorphism.

The text defines the map before Lemma 13.1.6 and says it permutes components. On a good system the bi-action is $\mathcal{U}(x,x') \to \mathcal{U}(x,x')$ `Chapter13/BiAction · EpGroupoid.GoodSystem.biact`, and it maps components onto components `Chapter13/BiAction · EpGroupoid.GoodSystem.image_biact_comp`. 1. The bi-action by (g',g) is continuous, so it maps the connected component of φ into a connected subset of $\mathcal{U}(x,x')$ containing $g' * \varphi * g$. That subset lies in the component of $g' * \varphi * g$. 2. The bi-action by (g'^{-1}, g^{-1}) maps that component back. So the image is the whole component.

Inversion maps components of $\mathcal{U}(x,x')$ onto components of $\mathcal{U}(x',x)$ by the same argument `Chapter13/BiAction · EpGroupoid.GoodSystem.image_inv_comp`. The components cover $\mathcal{U}(x,x')$ and are pairwise disjoint or equal `Chapter13/BiAction · EpGroupoid.GoodSystem.components`.

Two tools. - *Same source, left factor* `Chapter13/BiAction · EpGroupoid.GoodSystem.exists_biact_left_of_src`. Let $\psi_1, \psi_2 \in \mathcal{U}(x,x')$ have the same source. Then $\chi = \psi_2 \circ \psi_1^{-1}$ is a morphism from $t(\psi_1)$ to $t(\psi_2)$, two points of $U(x')$. So $\chi = \Gamma'(g', t\psi_1)$ for a unique g', and $\psi_2 = g' * \psi_1 * 1$. - *Same target, right factor* `Chapter13/BiAction · EpGroupoid.GoodSystem.exists_biact_right_of_tgt`. Morphisms with the same target differ by a right factor, by the same argument with $\psi_2^{-1} \circ \psi_1$.

Lemma 13.1.6 (stronger), p. 602. Let $\mathcal{U}$ be a good system and Σ a component of $\mathcal{U}(x,x')$.

(1) If $\psi \in \Sigma$ and $g' * \psi * 1 \in \Sigma$, then $g' = 1$ `Chapter13/BiAction · EpGroupoid.GoodSystem.eq_one_of_biact_left_mem`.

- $g' * \psi * 1$ has source $\Phi(1)(s\psi) = s\psi$.
- s is injective on Σ by condition (3), so $g' * \psi * 1 = \psi$.
- Left cancellation gives $\Gamma'(g', t\psi) = 1_{t\psi} = \Gamma'(1, t\psi)$, and injectivity of Γ' in the group element gives $g' = 1$.

The text's (1), $g' * \Sigma = \Sigma \Rightarrow g' = 1$, follows by applying this to one $\psi \in \Sigma$ `Chapter13/BiAction · EpGroupoid.GoodSystem.lemma_13_1_6_one`. The stronger form needs one morphism, not the whole component, and Proposition 13.1.9 uses it in that form.

(2) The same on the right: $\psi \in \Sigma$ and $1 * \psi * g \in \Sigma$ imply $g = 1$, using injectivity of t `Chapter13/BiAction · EpGroupoid.GoodSystem.eq_one_of_biact_right_mem` `Chapter13/BiAction · EpGroupoid.GoodSystem.lemma_13_1_6_two`.

(3) For two components Σ_1, Σ_2, the images $s(\Sigma_1)$ and $s(\Sigma_2)$ are equal or disjoint `Chapter13/BiAction · EpGroupoid.GoodSystem.lemma_13_1_6_three_src`, and so are $t(\Sigma_1)$ and $t(\Sigma_2)$ `Chapter13/BiAction · EpGroupoid.GoodSystem.lemma_13_1_6_three_tgt`.

- Suppose $s(\varphi_1) = s(\varphi_2)$ with $\varphi_i \in \Sigma_i$. By the first tool, $\varphi_2 = g' * \varphi_1 * 1$.
- The bi-action by $(g', 1)$ maps the component of φ_1 onto the component of φ_2, so $\Sigma_2 = g' * \Sigma_1$.
- Since $s(g' * \psi * 1) = s(\psi)$, this gives $s(\Sigma_2) = s(\Sigma_1)$.

No membership hypotheses on the components are needed: the component of a morphism outside $\mathcal{U}(x, x')$ is empty (decision (2)).

Stronger refers to (1) and (2), which need one morphism, not the whole component. The text proves (1) through the sc-diffeomorphism $s|_\Sigma$. The formal proof uses only injectivity, which is all that (3) of Definition 13.1.2 gives directly.

XIII.4 Theorem 13.1.7 (2017: Theorem 13.1), the stronger form: extending a family good on Q

The text states Theorem 13.1.7 (p. 602) for an open $Q \subset X$ with $|Q| = |X|$ and a good system of the full sub-ep-groupoid on Q. It extends that system to a good system of X that keeps the given neighbourhoods at the points of Q and has the new neighbourhoods inside given open sets. The formalization proves it twice: - a stronger form, here, for families good on Q in the sense of §XIII.2, with properness read in X; - the printed form, in §XIII.5, by showing that the printed hypothesis implies the stronger form's.

Transports `Chapter13/GoodSystemExistence · EpGroupoid.IsTransport`. Let $U \subset X$ be open and V another open set. A transport from U into V is a map σ from objects to morphisms with: - σ continuous and injective on U; - $t(\sigma(z)) = z$ for $z \in U$; - $s(\sigma(z)) \in V$ for $z \in U$.

The units $z \mapsto 1_z$ are a transport from U into U.

Condition (3) passes back along transports `Chapter13/GoodSystemExistence · EpGroupoid.injOn_comp_of_transport`. Let σ be a transport from U into V and σ' one from U' into V', with $s \circ \sigma$ injective on U and $s \circ \sigma'$ injective on U'. Suppose s and t are injective on every component of $\mathcal{U}(V, V')$. Then s and t are injective on every component of $\mathcal{U}(U, U')$. 1. Define $F(\varphi) = \sigma'(t\varphi)^{-1} \circ \varphi \circ \sigma(s\varphi)$ on $M = \mathcal{U}(U, U')$. The composite is defined because $t(\sigma(s\varphi)) = s\varphi$ and $t(\sigma'(t\varphi)) = t\varphi$. 2. F has source $s(\sigma(s\varphi)) \in V$ and target $s(\sigma'(t\varphi)) \in V'$, so F maps M into $\mathcal{U}(V, V')$. 3. F is continuous on M: it is built from σ, σ', s, t, composition and inversion, each continuous, through the composition lemma for continuous maps into composable pairs. 4. So F maps the component C of φ_0 in M, a connected set, into the component of $F(\varphi_0)$ in $\mathcal{U}(V, V')$, on which s and t are injective. 5. *Injectivity of s on C.* Let $\varphi_1, \varphi_2 \in C$ with $s\varphi_1 = s\varphi_2$. - $F(\varphi_1)$ and $F(\varphi_2)$ have the same source $s(\sigma(s\varphi_1))$, so by step 4 they are equal. -

Their targets agree, so $s(\sigma'(t\varphi_1)) = s(\sigma'(t\varphi_2))$, and injectivity of $s \circ \sigma'$ gives $t\varphi_1 = t\varphi_2$. - Cancelling the equal factors $\sigma'(t\varphi_i)^{-1}$ and $\sigma(s\varphi_i)$ in $F(\varphi_1) = F(\varphi_2)$ gives $\varphi_1 = \varphi_2$. 6. *Injectivity of t.* Symmetric, through σ.

A sheet around a morphism `Chapter13/GoodSystemExistence · EpGroupoid.exists_isOpen_injOn_src_tgt`. Every morphism ψ has an open neighbourhood on which s and t are both injective. Each is a local sc-diffeomorphism, so injective near ψ; intersect the two neighbourhoods.

A transport at each point `Chapter13/GoodSystemExistence · EpGroupoid.exists_transport_of_isGoodOn`. Let the family $(N(q))$ be good on Q, with $\pi(Q) = |X|$, and let $W \ni x$ be open. Then there are: - a point $q \in Q$; - a neighbourhood M of x with the natural action and proper closure, $M \subset W$; - a transport from M into $U(q)$ with $s \circ \sigma$ injective on M.

Case $x \in Q$. Take $q = x$, $M = N(x)$ (inside W by restricting to an invariant core, §XIII.1) and the unit transport.

Case $x \notin Q$. 1. Since $\pi(Q) = |X|$ there is $q \in Q$ and a morphism $\psi : q \to x$. 2. Take an open $O_0 \ni \psi$ on which s and t are injective, and set $O = O_0 \cap s^{-1}(U(q))$. 3. $t|_O$ is an injective local sc-diffeomorphism on the open set O, so it is an sc-diffeomorphism onto the open set $t(O) \ni x$ (§XIII.2). Its inverse on $t(O)$ is $\sigma = (t|_O)^{-1}$. 4. Choose M with the natural action and proper closure inside $W \cap t(O)$ (§XIII.1). 5. Then σ is continuous and injective on M, $t(\sigma(z)) = z$, and $s(\sigma(z)) \in U(q)$ since $\sigma(z) \in O$. And $s \circ \sigma$ is injective because s is injective on O and σ is injective.

Theorem 13.1.7, stronger form (stronger), p. 602 `Chapter13/GoodSystemExistence · EpGroupoid.theorem_13_1_7`. Let $Q \subset X$ with $\pi(Q) = |X|$, let $(N(q))$ be good on Q (§XIII.2), and for $y \notin Q$ let $W(y) \ni y$ be open. Then there is a good system $\mathcal{U}$ of X with: - $N_{\mathcal{U}}(q) = N(q)$ for $q \in Q$; - $U(y) \subset W(y)$ for $y \notin Q$.

Proof. 1. *Choices.* For every y, choose the data of the previous lemma with $W = W(y)$ for $y \notin Q$ (and $W = X$ for $y \in Q$): - a point $q_y \in Q$; - a neighbourhood $M(y)$; - a transport σ_y from $M(y)$ into $U(q_y)$.

For $y \in Q$ the lemma's first case keeps $M(y) = N(y)$. 2. *The family is good on X.* - Each $M(y)$ has the natural action and proper closure. - Condition (3) for $\mathcal{U}(y, y')$ follows from condition (3) for $\mathcal{U}(q_y, q_{y'})$, which holds since the family is good on Q. The step is the transport lemma with $\sigma = \sigma_y$, $\sigma' = \sigma_{y'}$. 3. *A family good on all of X is a good system* `Chapter13/GoodSystem · EpGroupoid.GoodSystem.ofIsGoodOn`.

Where the formal proof departs from the text, and why stronger. The text's hypothesis is a good system of the full sub-ep-groupoid Q, with properness read in Q, and Q open. Here properness is read in X and Q is any set meeting every orbit. The text also asks the new $U(y)$ to have closures with a further smallness condition; it is not used, and the conclusion holds without it. The printed form is derived from this one in §XIII.5.

XIII.5 Theorem 13.1.7 (2017: Theorem 13.1) as printed: properness in the full subcategory on Q

The full subcategory on Q. For $Q \subset X$, the morphisms of the full subcategory are the morphisms with source and target in Q. Its source and target maps are the restrictions `Chapter13/GoodSystemRelative · EpGroupoid.subSrc` `Chapter13/GoodSystemRelative · EpGroupoid.subTgt`, valued in Q with the subspace topology. - A subset $A \subset Q$ is *proper in Q* if $t : s^{-1}(A) \to Q$ is proper in the subcategory `Chapter13/GoodSystemRelative · EpGroupoid.IsProperSubsetIn`. - A family $(N(q))_{q \in Q}$ is a *good system for Q* `Chapter13/`

GoodSystemRelative · EpGroupoid.IsGoodIn if for $q, q' \in Q$: - $U(q) \subset Q$; - $\mathrm{cl}_Q U(q)$ is proper in Q (Definition 13.1.2 (1) read in Q); - condition (3) holds on $\mathcal{U}(q, q')$.

Conditions (2) and (3) are the same in Q and in X: - a natural representation of G_q whose domain lies in Q is one for the ep-groupoid Q; - $\mathcal{U}(q, q')$ is the same set of morphisms in both, since the subcategory is full.

No sub-ep-groupoid structure is built. The subcategory is its set of morphisms with the restricted maps, which is all the printed hypothesis refers to.

Every good system of X is a good system for $Q = X$ Chapter13/GoodSystemRelative · EpGroupoid.GoodSystem.isGoodIn_univ. With Theorem 13.1.8 this is the witness of the notion.

Properness by ultrafilters (extra) Chapter13/GoodSystemRelative · EpGroupoid.isProperMap_iff_ultrafilter_of_isInducing. Let f be a continuous map defined on a subspace S of a space T. Then f is proper iff the following holds. For every ultrafilter $\mathcal{F}$ on T that contains S and whose image under f converges to some b, $\mathcal{F}$ converges to some $a \in S$ with $f(a) = b$. This is Mathlib's characterization of proper maps by ultrafilters, transported along the inclusion of the subspace. It turns the two properness notions into statements about ultrafilters of morphisms: - in X Chapter13/GoodSystemRelative · EpGroupoid.isProperSubset_iff_ultrafilter; - in Q Chapter13/GoodSystemRelative · EpGroupoid.isProperSubsetIn_iff_ultrafilter.

Two tools. - Chapter13/GoodSystemRelative · EpGroupoid.exists_mor_tgt_mem: if $\pi(Q) = |X|$, every object z has a morphism $z \to q''$ with $q'' \in Q$. It is the inverse of a morphism from a point of Q to z. - Chapter13/GoodSystemRelative · EpGroupoid.exists_localSection: through a morphism χ with target in an open O there is a local section σ of s near $s(\chi)$, continuous, with: - $\sigma(s\chi) = \chi$; - $s(\sigma(z)) = z$; - $t(\sigma(z)) \in O$.

It is the local inverse of the local homeomorphism s at χ, cut down by the continuity of t to the preimage of O.

Step 1: the closure stays in Q Chapter13/GoodSystemRelative · EpGroupoid.closure_subset_of_isProperSubsetIn. Let Q be open with $\pi(Q) = |X|$, $U \subset Q$, and $\mathrm{cl}_Q U$ proper in Q. Then $\mathrm{cl}_X U \subset Q$. 1. Let $z \in \mathrm{cl}_X U$. Choose $\chi : z \to q''$ with $q'' \in Q$, and a local section σ of s through χ, defined on an open $V \ni z$, with targets in Q. 2. Let $\mathcal{F}$ be an ultrafilter finer than the filter of neighbourhoods of z within $U \cap V$. It is nontrivial because $z \in \mathrm{cl}\, U$ and V is a neighbourhood of z. 3. Push $\mathcal{F}$ forward by σ. For $y' \in U \cap V$, $\sigma(y')$ is a morphism with source $y' \in U \subset Q$ and target in Q, a morphism of the subcategory with source in $\mathrm{cl}_Q U$. Its targets $t(\sigma(y'))$ converge to $t(\chi) = q'' \in Q$, by continuity. 4. By properness in Q, read through ultrafilters, the pushed ultrafilter converges in the subcategory to a morphism ρ with $t(\rho) = q''$. 5. The pushed ultrafilter also converges in X to $\sigma(z) = \chi$, by continuity of σ. Limits in the Hausdorff space of morphisms are unique, so $\rho = \chi$. 6. Since ρ is a morphism of the subcategory, its source z lies in Q.

Step 2: properness in X Chapter13/GoodSystemRelative · EpGroupoid.isProperSubset_of_isProperSubsetIn. Under the same hypotheses, $t : s^{-1}(\mathrm{cl}_X U) \to X$ is proper. 1. By Step 1, $\mathrm{cl}_X U = \mathrm{cl}_Q U$. 2. Let $\mathcal{F}$ be an ultrafilter of morphisms with sources in $\mathrm{cl}_X U$ whose targets converge to $y \in X$. 3. Choose $\chi : y \to q''$ with $q'' \in Q$, and a local section ρ of s through χ with targets in Q. 4. $F(\varphi) = \rho(t\varphi) \circ \varphi$ is defined eventually along $\mathcal{F}$. It is a morphism of the subcategory with source $s\varphi \in \mathrm{cl}_Q U$ and target $t(\rho(t\varphi)) \in Q$, and these targets converge to $t(\chi) = q''$. 5. By properness in Q the image ultrafilter converges to some morphism ψ. 6. Then $\varphi = \rho(t\varphi)^{-1} \circ F(\varphi)$ converges to $\chi^{-1} \circ \psi$, by continuity of inversion and composition. This is a limit of $\mathcal{F}$ with target y.

The converse Chapter13/GoodSystemRelative · EpGroupoid.isProperSubsetIn_of_isProperSubset. Properness in X to-

gether with $\mathrm{cl}_X U \subset Q$ gives properness in Q. An ultrafilter in the subcategory whose targets converge in Q has, by properness in X, a limit, whose source lies in $\mathrm{cl}_X U \subset Q$ and whose target is the limit in Q, so it is a morphism of the subcategory.

Consequence `Chapter13/GoodSystemRelative · EpGroupoid.isGoodIn_iff`. For open Q with $\pi(Q) = |X|$, a family is a good system for Q iff it is good on Q in the sense of §XIII.2 and $\mathrm{cl}_X U(q) \subset Q$ for all $q \in Q$.

Theorem 13.1.7, as printed (stronger), p. 602 `Chapter13/GoodSystemRelative · EpGroupoid.theorem_13_1_7_book`. Let Q be open with $|Q| = |X|$ and $(N(q))_{q\in Q}$ a good system for the ep-groupoid Q. Given open $W(y) \ni y$ for $y \notin Q$, there is a good system of X that keeps $N(q)$ for $q \in Q$ and has $U(y) \subset W(y)$ for $y \notin Q$.

Proof. 1. A good system for Q is good on Q `Chapter13/GoodSystemRelative · EpGroupoid.IsGoodIn.isGoodOn`, by Step 2. 2. The stronger form of §XIII.4 applies `Chapter13/GoodSystemExistence · EpGroupoid.theorem_13_1_7`.

No hypothesis is added. The text writes $|Q| = |Y|$ for $\pi(Q) = |X|$. The verdict is "stronger" because the conclusion omits nothing and the smallness condition on the new closures is not required. That condition is a property of the text's construction, not used afterwards in the chapter.

XIII.6 Theorem 13.1.8 (2017: Theorem 13.2): good systems exist on paracompact orbit spaces

Finitely many morphisms into a point, and one sheet for a connected set `Chapter13/GoodSystemExistence · EpGroupoid.exists_nhds_injOn_of_isProperSubset`. Let $A_1, \dots, A_n$ be closed sets with proper closure (the properness property), $A = \bigcup_i A_i$, and $y \in X$. Then there is an open $V \ni y$ such that, for every preconnected set C of morphisms from A to V, s and t are injective on C. 1. Θ *is finite.* Let $\Theta = \{\varphi : s\varphi \in A,\ t\varphi = y\}$. For each i, the morphisms with source in A_i and target y form a fibre of the proper map t on $s^{-1}(A_i)$. The map t is locally injective, so this fibre is discrete and compact, hence finite. A finite union of finite sets is finite. 2. *Separating sheets.* For each $\theta \in \Theta$ choose an open sheet $O'(\theta) \ni \theta$ on which s and t are injective (§XIII.4). Shrink them to be pairwise disjoint, by Hausdorff separation of the finitely many points of Θ. Let $\Omega = \bigcup_\theta O'(\theta)$, an open set. 3. *Closed images.* $B_i = t(s^{-1}(A_i) \setminus \Omega)$ is closed, since $s^{-1}(A_i) \setminus \Omega$ is closed in $s^{-1}(A_i)$ and the proper map t is closed. Also $y \notin B_i$, since every morphism from A_i to y is in $\Theta \subset \Omega$. 4. *The neighbourhood.* $V = \bigcap_i B_i^c$ intersected with $\bigcap_\theta t(O'(\theta))$ is open and contains y. 5. *A connected set lies in one sheet.* Let C be preconnected with sources in A and targets in V. Every $\varphi \in C$ lies in Ω, since otherwise $t\varphi \in B_i$ for some i. The $O'(\theta)$ are disjoint and open, so the preconnected C lies in one of them, on which s and t are injective.

Theorem 13.1.8 (same), p. 604 `Chapter13/GoodSystemExistence · EpGroupoid.theorem_13_1_8`. If $|X|$ is paracompact, then for every family of open $W(x) \ni x$ there is a good system with $U(x) \subset W(x)$ for all x.

Reading. The text's "for all $\in X$" is read as "for all $x \in X$".

Proof, following the text's steps. 1. *Neighbourhoods with proper closure.* For each x choose a neighbourhood $N_0(x)$ with the natural action and proper closure inside $W(x)$ (§XIII.1). 2. *A locally finite shrinking in* $|X|$. The sets $\pi(U_0(x))$ are open in $|X|$, because π is open (Proposition 7.1.8, Part VII), and cover $|X|$. - Paracompactness gives a locally finite open refinement $(\tilde v_a)_a$ with $\tilde v_a \subset \pi(U_0(a))$. - The shrinking lemma for point-finite covers of a normal space gives open $\tilde v_a'$ with $\mathrm{cl}\,\tilde v_a' \subset \tilde v_a$, still covering. The paracompact Hausdorff space $|X|$ is normal (Part VII). - The closures $\mathrm{cl}\,\tilde v_a'$ are locally finite. 3. *The set*

V. Let $V_a = \pi^{-1}(\tilde{v}'_a) \cap U_0(a)$ and $V = \bigcup_a V_a$. - V is open and $\pi(V) = |X|$. - By Lemma 13.1.1 (□), $\operatorname{cl} V_a \subset U_0(a)$, since $\operatorname{cl} \pi(V_a) \subset \operatorname{cl} \tilde{v}'_a \subset \pi(U_0(a))$. So each $\operatorname{cl} V_a$ has the properness property. - The V_a are locally finite, and $\operatorname{cl} V = \bigcup_a \operatorname{cl} V_a$. 4. *Finitely many pieces near each point.* For each x there are an open $G \ni x$ and a finite set F of indices such that every morphism φ with $s\varphi \in \operatorname{cl} V$ and $t\varphi \in G$ has $s\varphi \in \operatorname{cl} V_a$ for some $a \in F$. - Take $G = \pi^{-1}(\tilde{N})$, with $\tilde{N}$ a neighbourhood of $\pi(x)$ meeting only finitely many $\operatorname{cl} \tilde{v}'_a$. - $\pi(s\varphi) = \pi(t\varphi) \in \tilde{N}$, and $s\varphi \in \operatorname{cl} V_a$ for some a; that $\operatorname{cl} \tilde{v}'_a$ meets $\tilde{N}$, so $a \in F$. 5. *The neighbourhoods at points of V.* For $x \in V$: - take G and F from step 4, and V' from the sheet lemma for $A_a = \operatorname{cl} V_a$, $a \in F$, and $y = x$; - let $N_1(x)$ be the invariant core of $N_0(x)$ in $V \cap G \cap V'$.

Then $N_1(x) \subset W(x)$, it has proper closure (a closed subset of $\operatorname{cl} U_0(x)$), and $U_1(x) \subset V$. For a preconnected set C of morphisms from $\operatorname{cl} V$ to $U_1(x)$, steps 4 and the sheet lemma give s, t injective on C. For $x \notin V$ keep $N_1(x) = N_0(x)$. 6. *Good on V.* For $q, q' \in V$ and a component Σ of $\mathcal{U}(q, q')$: - the sources of Σ lie in $U_1(q) \subset V \subset \operatorname{cl} V$ and its targets in $U_1(q')$; - Σ is connected, so by step 5 at q' the maps s and t are injective on it; - Σ is open, so it is a diffeo-component.

The other two conditions of "good on V" are in step 5. 7. *Extension.* The stronger Theorem 13.1.7 (§XIII.4), with $Q = V$, gives a good system that keeps $N_1(q)$ on V and has $U(y) \subset W(y)$ off V.

Where the formal proof departs from the text. The steps are the text's. The separation of the finitely many morphisms in the sheet lemma uses only Hausdorff separation and the properness of t, and metrizability of $|X|$ is not used anywhere. The neighbourhoods off V come from the stronger Theorem 13.1.7, so the smallness of their closures that the printed Theorem 13.1.7 arranges is not needed.

The witness `Chapter13/GoodSystemExistence · EpGroupoid.nonempty_goodSystem_trivial`. For every paracompact Hausdorff M-polyfold Z, the trivial ep-groupoid on Z (only units) has paracompact orbit space $|X| = Z$ `Chapter7/EpGroupoid · EpGroupoid.hasParacompactOrbitSpace_trivial`. Theorem 13.1.8 gives it a good system. So Definition 13.1.2 is not vacuous.

XIII.7 Proposition 13.1.9 (2017: Proposition 13.2)

Stabilizers and D_Σ. Let $\mathcal{U}$ be a good system and Σ a component of $\mathcal{U}(x, x')$. - $G_{x,\Sigma}$ is the set of $g \in G_x$ with $g * s(\Sigma) = s(\Sigma)$ `Chapter13/BiAction · EpGroupoid.GoodSystem.stabSrc`. - $G_{x',\Sigma}$ is the set of $g' \in G_{x'}$ with $g' * t(\Sigma) = t(\Sigma)$ `Chapter13/BiAction · EpGroupoid.GoodSystem.stabTgt`.

Both are subgroups. The map

$$D_\Sigma = t \circ (s|_\Sigma)^{-1} : s(\Sigma) \to t(\Sigma)$$

`Chapter13/BiAction · EpGroupoid.GoodSystem.D` is an sc-diffeomorphism with inverse $s \circ (t|_\Sigma)^{-1}$ `Chapter13/BiAction · EpGroupoid.GoodSystem.isScDiffeoOn_D`. It is a composite of the sc-diffeomorphisms $(s|_\Sigma)^{-1}$ and $t|_\Sigma$ of §XIII.2.

Proposition 13.1.9 (stronger), p. 607 `Chapter13/BiAction · EpGroupoid.GoodSystem.proposition_13_1_9`. There is a group isomorphism $G_{x,\Sigma} \to G_{x',\Sigma}$, $g \mapsto g'(g)$, with

$$(s|_\Sigma)^{-1}(g * z) = g'(g) * (s|_\Sigma)^{-1}(z) * g^{-1} \quad \text{for } z \in s(\Sigma),$$

and every map $G_{x,\Sigma} \to G_{x',\Sigma}$ with this property equals it.

Proof. 1. *The partner exists.* Let $g \in G_{x,\Sigma}$ and $\varphi \in \Sigma$. The morphism $1 * \varphi * g^{-1}$ has source $g * s(\varphi)$, which lies in $s(\Sigma)$ since g stabilizes $s(\Sigma)$. So there is $\psi \in \Sigma$ with the same source, and by the first tool of §XIII.3,

$\psi = g' * (1 * \varphi * g^{-1}) * 1 = g' * \varphi * g^{-1}$ for some g'. Thus there is g' with $g' * \varphi * g^{-1} \in \Sigma$. 2. *It is unique* `Chapter13/BiAction · EpGroupoid.GoodSystem.partner`. - *Left uniqueness.* If $g'_1 * \varphi * g^{-1}$ and $g'_2 * \varphi * g^{-1}$ both lie in Σ, they have the same source, so they are equal by injectivity of s on Σ. Left cancellation in the bi-action gives $g'_1 = g'_2$. - *Right uniqueness.* If $g' * \varphi * g_1$ and $g' * \varphi * g_2$ both lie in Σ, injectivity of t on Σ and right cancellation give $g_1 = g_2$. 3. *It does not depend on φ.* The bi-action by (g', g^{-1}) maps the component of φ, which is Σ, onto the component of $g' * \varphi * g^{-1}$, which is Σ again. So $g' * \psi * g^{-1} \in \Sigma$ for every $\psi \in \Sigma$, with the same g'. 4. *It lies in $G_{x',\Sigma}$.* $t(g' * \psi * g^{-1}) = g' * t(\psi)$, so $g' * t(\Sigma) \subset t(\Sigma)$, with equality by the same argument for the inverse. And it satisfies the identity: for $z = s(\psi)$, $(s|_\Sigma)^{-1}(g * z) = g' * \psi * g^{-1}$, since the right side lies in Σ and has source $g * z$. 5. *A homomorphism* `Chapter13/BiAction · EpGroupoid.GoodSystem.partnerHom`. For g, h: $(g'(g)g'(h)) * \varphi * (gh)^{-1} = g'(g) * (g'(h) * \varphi * h^{-1}) * g^{-1}$ by the action law, and it lies in Σ. Left uniqueness gives $g'(gh) = g'(g)g'(h)$. 6. *Bijective.* - Injective: if $g'(g_1) = g'(g_2)$ then $g'(g_1) * \varphi * g_1^{-1}$ and $g'(g_1) * \varphi * g_2^{-1}$ lie in Σ, and right uniqueness gives $g_1 = g_2$. - Surjective: for $k \in G_{x',\Sigma}$, the second tool of §XIII.3 applied to $k * \varphi * 1$ and an element of Σ with the same target gives h with $k * \varphi * h \in \Sigma$. One checks $h^{-1} \in G_{x,\Sigma}$, and its partner is k. 7. *Uniqueness among all maps.* If $f : G_{x,\Sigma} \to G_{x',\Sigma}$ satisfies the identity, then at $z = s(\varphi)$ the identity says $f(g) * \varphi * g^{-1} = (s|_\Sigma)^{-1}(g * z) \in \Sigma$. Left uniqueness gives $f(g) = g'(g)$.

Equivariance of D_Σ `Chapter13/BiAction · EpGroupoid.GoodSystem.proposition_13_1_9_D`: $\Phi'(g'(g)) \circ D_\Sigma = D_\Sigma \circ \Phi(g)$ on $s(\Sigma)$. Apply t to the identity of the proposition: $t(g' * \psi * g^{-1}) = g' * t(\psi)$.

Where the formal proof departs from the text, and why stronger. The text proves the identity through the smoothness of a map Θ_g and a connectedness argument on it, and states uniqueness for homomorphisms. The formal proof uses only Lemma 13.1.6 in its one-morphism form, with the action laws and the cancellations. The uniqueness it proves is among all maps, not only homomorphisms.

XIII.8 Definition 13.2.1 recalled, sc⁺-sections on open sets, and Definitions 13.2.2–13.2.4 (2017: Definitions 13.4–13.7): supports, norms, triviality

Definition 13.2.1 (p. 607). $\Lambda : W \to \mathbb{Q}^+$ is an sc⁺-multisection in Chapter 11's sense `Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsScPlusMultisection` (Definition 13.2.1, Part XI) if two conditions hold. - Λ is a functor: $\Lambda(\mu(\varphi, w)) = \Lambda(w)$ whenever $P(w) = s(\varphi)$. - Every point x has a *local section structure*: an open $O \ni x$, finitely many sc⁺-sections $s_1, \dots, s_k$ on O, and weights $\sigma_1, \dots, \sigma_k \in \mathbb{Q}^+$, $\sigma_i > 0$, with $\sum_i \sigma_i = 1$ and

$$\Lambda(w) = \sum_{i : s_i(P(w)) = w} \sigma_i \quad \text{for } P(w) \in O$$

`Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsLocalRepOn`.

This is the definition the whole chapter builds on. The structures of §§13.2–13.5 are additional data on such a functor.

Sc⁺-sections on an open set. An sc⁺-section on an open U is a section of P over U with values in $W_{0,1}$ that is sc-smooth as a map into $W_{0,1}$ (Chapter 11). Chapter 13 needs sums, multiples and cut-offs of such sections. The formalization proves the following. - *Characterization by charts.* Being sc⁺ on U can be tested on chart representatives near each point: the representative of the section in a strong bundle chart, read on

the $(0,1)$-level Chapter13/ScPlusSectionOn · SBLocalization.isScPlusSectionOn_of_localRepOne. - *Values in $W_{0,1}$.* The values of an sc⁺-section lie in $W_{0,1}$ Chapter13/ScPlusSectionOn · SBLocalization.IsScPlusSectionOn.mem_oneSet. - *Sums and multiples.* $s_1 + s_2$ is sc⁺ on U Chapter13/ScPlusSectionOn · SBLocalization.IsScPlusSectionOn.sectionAdd. So is βs for an sc-smooth $\beta : U \to \mathbb{R}$ Chapter13/ScPlusSectionOn · SBLocalization.IsScPlusSectionOn.sectionSmul, and in particular as for a constant a Chapter13/ScPlusSectionOn · SBLocalization.IsScPlusSectionOn.sectionSmul_const. Finite sums are sc⁺ Chapter13/ScPlusSectionOn · SBLocalization.isScPlusSectionOn_sectionSum, and the zero section is sc⁺ Chapter13/ScPlusSectionOn · SBLocalization.isScPlusSectionOn_fiberZero. In charts the fibres are linear and the operations are sc-smooth maps of the fibre coordinates, sc⁺ preserved. - *Extension by zero.* A section defined on U is extended by 0 off U Chapter13/ScPlusSectionOn · SBLocalization.extendZero, agrees with the original on U Chapter13/ScPlusSectionOn · SBLocalization.extendZero_eqOn, and is again sc⁺ on U Chapter13/ScPlusSectionOn · SBLocalization.IsScPlusSectionOn.extendZero. A local section structure can be replaced by the extended sections Chapter13/ScPlusSectionOn · SBLocalization.IsLocalRepOn.extendZero. This makes all local sections functions on all objects, which the transports of Lemma 13.2.6 need.

Definition 13.2.2 (same), p. 608 Chapter13/MultisectionSupport · SBLocalization.domSupp Chapter13/MultisectionSupport · SBLocalization.supp Chapter13/MultisectionSupport · SBLocalization.suppAt. - The *domain support* is $\mathrm{dom\text{-}supp}(\Lambda) = \mathrm{cl}\{x : \exists w \in W_x,\ w \neq 0_x,\ \Lambda(w) > 0\}$. - The *support* is $\mathrm{supp}(\Lambda) = \{w : \Lambda(w) > 0\}$, with fibres $\mathrm{supp}(\Lambda)(x)$.

The text then claims several facts. Each is proved. Let Λ be an sc⁺-multisection and (s_i, σ_i) a local section structure on O. 1. *On O the support is the set of section values* Chapter13/MultisectionSupport · SBLocalization.IsLocalRepOn.suppAt_eq: $\mathrm{supp}(\Lambda)(x) = \{s_1(x), \dots, s_k(x)\}$ for $x \in O$. If $w = s_i(x)$ then $\Lambda(w) \geq \sigma_i > 0$. Conversely, if $\Lambda(w) > 0$ the sum defining $\Lambda(w)$ is nonempty, so $w = s_i(x)$ for some i. 2. *Finite* Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.finite_suppAt: from 1, at most k elements. 3. *The weights over a point sum to* 1 Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.sum_suppAt Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.finsum_suppAt. Group the indices i by the value $s_i(x)$: $\sum_{w \in \mathrm{supp}(\Lambda)(x)} \Lambda(w) = \sum_w \sum_{i : s_i(x) = w} \sigma_i = \sum_i \sigma_i = 1$. 4. *Nonempty* Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.suppAt_nonempty: an empty sum is $0 \neq 1$. 5. *Domain support as a closure* Chapter13/MultisectionSupport · SBLocalization.domSupp_eq_closure_image: $\mathrm{dom\text{-}supp}(\Lambda) = \mathrm{cl}\, P(\mathrm{supp}(\Lambda) \setminus 0_W)$, which is the definition rewritten.

Definition 13.2.3 (restated), p. 608 Chapter13/MultisectionSupport · SBLocalization.pointwiseNorm. For an auxiliary norm N on $W_{0,1}$ (Definition 8.3.5, Part VIII), the pointwise norm is $N(\Lambda)(x) = \max\{N(w) : w \in \mathrm{supp}(\Lambda)(x)\}$. - N is read on all of W by setting it 0 off $W_{0,1}$ Chapter13/MultisectionSupport · SBLocalization.normW. The values of sc⁺-sections, and so the support, lie in $W_{0,1}$ Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.suppAt_subset_oneSet, where N is the given norm. - The maximum is written as a supremum. It is attained Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.isGreatest_pointwiseNorm, because the support over x is finite and nonempty (2 and 4 above). - For an auxiliary norm, $\mathrm{dom\text{-}supp}(\Lambda) = \mathrm{cl}\{x : N(\Lambda)(x) > 0\}$ Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.domSupp_eq_closure_pointwiseNorm. $N(\Lambda)(x) > 0$ iff some $w \in \mathrm{supp}(\Lambda)(x)$ has $N(w) > 0$, iff some such w is not 0_x, since an auxiliary norm vanishes exactly at 0 Chapter13/MultisectionSupport · SBLocalization.normW_eq_zero_iff.

Restated: the maximum of the text is a supremum shown to be a maximum, and N is extended by 0 off $W_{0,1}$, where it is never evaluated on the support.

Definition 13.2.4 (same), p. 609 Chapter13/MultisectionSupport · SBLocalization.IsTrivialOn. Λ is trivial on V if $\Lambda(0_x) = 1$ for all $x \in V$. - The text's "and hence $\Lambda(w) = 0$ for $w \neq 0_x$" is proved: $\Lambda(0_x) = 1$ iff $\Lambda(w) = 0$ for all $w \neq 0_x$ in W_x Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.apply_

`fiberZero_eq_one_iff`, because the weights over x sum to 1 (3 above). - dom-supp(Λ) is the smallest closed set off which Λ is trivial `Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.isLeast_domSupp`. - Off dom-supp(Λ) no $w \neq 0$ has positive weight, so Λ is trivial there. - If Λ is trivial off a closed C, then every x with some $w \neq 0_x$, $\Lambda(w) > 0$, lies in C, and so does the closure of the set of such x. - The *zero multisection* has $\Lambda(0_x) = 1$ and $\Lambda(w) = 0$ for $w \neq 0$. It is an sc⁺-multisection, with the zero section of weight 1, and it is trivial everywhere `Chapter13/MultisectionSupport · SBLocalization.isTrivialOn_zeroMultisection`. It is the witness for every notion of this section.

XIII.9 Definition 13.2.5 (2017: Definition 13.8) and Lemma 13.2.6 (2017: Lemma 13.3): symmetric structures

Transported sections `Chapter13/MultisectionSymmetric · SBLocalization.transportSection`. For a map τ from objects to morphisms and a map b from objects to W with $P(b(z)) = s(\tau(z))$, the transported section is $z \mapsto \mu(\tau(z), b(z))$. It is an sc⁺-section on U when: - τ is sc-smooth on U; - b is sc⁺ along $s \circ \tau$; - $t(\tau(z)) = z$

`Chapter13/MultisectionSymmetric · SBLocalization.isScPlusSectionOn_transportSection`. The action μ is an sc-smooth strong bundle map on the fibred product (Chapter 8, Part VIII), and it preserves the $(0,1)$-level. Every construction in this chapter that moves a section along morphisms is a transported section.

Definition 13.2.5 (restated), p. 610 `Chapter13/MultisectionSymmetric · SBLocalization.SymmetricStructure`. A symmetric structure of Λ at x consists of: - the domain $U(x)$ of a natural representation of G_x with the properness property; - a finite index set I_x with an action of G_x; - sc⁺-sections s_i on $U(x)$, $i \in I_x$, with - (1) $s_{g(i)}(g * y) = \mu(\Gamma(g, y), s_i(y))$ for $y \in U(x)$; - (2) $\Lambda(w) = |I_x|^{-1} \#\{i : s_i(P(w)) = w\}$ for $P(w) \in U(x)$.

Restated: "G_x-invariant with the natural action" is read as the domain of a natural representation, the reading of Chapter 11. The index set lives in the universe of the isotropy groups. The version on neighbourhoods with the natural action, which the good systems need, is below.

Equal weights `Chapter13/MultisectionSymmetric · SBLocalization.IsLocalRepOn.exists_equal_weights`. A local section structure $(s_i, \sigma_i)_{i \le k}$ on O can be rewritten with all weights equal. 1. Write $\sigma_i = n_i/d_i$ and $p = \prod_j d_j$. 2. Set $m_i = n_i \prod_{j \neq i} d_j$, so $\sigma_i = m_i/p$. 3. Take the index type $\coprod_i \{1, \dots, m_i\}$, the section s_i on each of the m_i copies, and the common weight $1/p$. 4. The count is unchanged: $\sum_{(i,r):s_i=w} 1/p = \sum_{i:s_i=w} m_i/p$.

The total number of indices is $\sum_i m_i = p \sum_i \sigma_i = p$. This is the text's $k_j q$.

Lemma 13.2.6 (same), p. 610 `Chapter13/MultisectionSymmetric · SBLocalization.lemma_13_2_6`. Every sc⁺-multisection has a symmetric structure at every point. The proof is the text's, before Definition 13.2.5. 1. *A local structure on a natural domain.* - Take a local section structure (s_i, σ_i) on an open $O \ni x$. - Take a natural representation of G_x with the properness property on a domain $U \subset O$ (Theorem 7.1.13 with the properness property, Part VII). - Restrict the structure to U and extend the sections by 0 off U (§XIII.8). 2. *Equal weights.* Rewrite with equal weights $1/p$ on an index type I_1 with $|I_1| = p$. 3. *Symmetrize.* - Let $\hat{I} = I_1 \times G_x$, with $h \cdot (j, g) = (j, hg)$ `Chapter13/MultisectionSymmetric · SBLocalization.prodIsotropyAction`. - Let $S_{(j,g)}(z) = \mu(\Gamma(g, g^{-1} * z), t_j(g^{-1} * z))$, the section t_j moved by g: the transported section with $\tau(z) = \Gamma(g, g^{-1} * z)$, whose target is z. - These are sc⁺ on U `Chapter13/MultisectionSymmetric · SBLocalization.isScPlusSectionOn_transportSection`, since $\Phi(g^{-1})$ and $\Gamma(g, \cdot)$ are sc-smooth. 4. *Equivariance (1).* We need $S_{(j,hg)}(h * z) = \mu(\Gamma(h, z), S_{(j,g)}(z))$. - The left side is

$\mu(\Gamma(hg, g^{-1} * z), t_j(g^{-1} * z))$. - By $\Gamma(hg, u) = \Gamma(h, g * u) \circ \Gamma(g, u)$ with $u = g^{-1} * z$, and the composition law $\mu(\psi \circ \chi, w) = \mu(\psi, \mu(\chi, w))$, this is the right side. 5. *The count (2).* Fix w with $P(w) = z \in U$. - For each g, let $w_g = \mu(\Gamma(g, g^{-1} * z)^{-1}, w)$, a vector over $g^{-1} * z$. - $\mu(\Gamma(g, \cdot), \cdot)$ is a bijection of fibres, so $S_{(j,g)}(z) = w$ iff $t_j(g^{-1} * z) = w_g$. - Λ is a functor, so $\Lambda(w_g) = \Lambda(w)$. By the equal-weight structure, $\#\{j : t_j(g^{-1} * z) = w_g\} = p\Lambda(w)$. - Summing over the $|G_x|$ values of g: $\#\{(j, g) : S_{(j,g)}(z) = w\} = |G_x| p\Lambda(w) = |\hat{I}|\Lambda(w)$.

Neighbourhoods with the same action `Chapter13/SymmetricOn · EpGroupoid.NatNbhd.Le`. For two neighbourhoods N_1, N_2 of x with the natural action, $N_1 \leq N_2$ means: - $U_1 \subset U_2$; - $\Gamma_1(g, z) = \Gamma_2(g, z)$ for $z \in U_1$, hence also $\Phi_1(g) = \Phi_2(g)$ on U_1.

It is reflexive and transitive. Two neighbourhoods with the same natural representation are comparable.

A common refinement `Chapter13/SymmetricOn · EpGroupoid.NatNbhd.exists_le_of_finite`. Given a neighbourhood N_0, finitely many neighbourhoods $N_1, \dots, N_m$ of x with the natural action, and an open $V \ni x$, there is $M \leq N_0$, $M \leq N_i$ for all i, with $U_M \subset V$ and the representation of N_0. 1. Two natural representations of G_x agree on the connected component of x in the intersection of their domains, by the uniqueness of natural representations (Theorem 7.1.13, Part VII). 2. The component of x in the open set $U_{R_0} \cap \bigcap_i U_{R_i}$ is open, by local connectedness. 3. On it all the Γ_i agree with Γ_0. 4. The invariant core (§XIII.1) of N_0 inside this component, intersected with V and all U_i, is the required M.

This lemma is what makes the intersections in Definitions 13.2.9 and 13.2.12 meaningful.

Moving vectors along morphisms `Chapter13/SymmetricOn · SBLocalization.fibAct`. $\mu(\psi, v)$ is written for v over $s(\psi)$, and set to v otherwise, so that it is a total function. It lands over $t(\psi)$ and maps 0 to 0. It is additive and homogeneous on sections: - $\mu(\psi, s_1 + s_2) = \mu(\psi, s_1) + \mu(\psi, s_2)$ `Chapter13/SymmetricOn · SBLocalization.fibAct_sectionAdd`; - $\mu(\psi, \beta s) = \beta\mu(\psi, s)$ `Chapter13/SymmetricOn · SBLocalization.fibAct_sectionSmul`; - $\mu(\psi, \sum_l s_l) = \sum_l \mu(\psi, s_l)$ `Chapter13/SymmetricOn · SBLocalization.fibAct_sectionSum`,

because $\mu(\psi, \cdot)$ is a linear isomorphism of fibres (Definition 8.3.1, Part VIII). These identities make every new family below equivariant and compatible with correspondences.

Symmetric structures on a neighbourhood with the natural action `Chapter13/SymmetricOn · SBLocalization.SymmetricStructureOn`. This is Definition 13.2.5 on a neighbourhood N of §XIII.1 instead of a natural domain. It consists of: - a finite index type I with a G_x-action; - sc$^+$-sections s_i on U, equivariant through Γ of N; - the counting formula over U.

Its first properties: - $I \neq \emptyset$ `Chapter13/SymmetricOn · SBLocalization.SymmetricStructureOn.card_pos`. Over x the support of Λ is nonempty (§XIII.8), and a nonempty count needs an index. - $|I|^{-1}$ summed over I is 1. - *Where $\Lambda(0_y) = 1$ all sections vanish at y* `Chapter13/SymmetricOn · SBLocalization.SymmetricStructureOn.s_eq_fiberZero`. The count of 0_y is $|I|^{-1}\#\{i : s_i(y) = 0_y\} = 1$, so every i counts. The tight structures (§XIII.17) and the atomic structures (§XIII.26) use this. - *Restriction* `Chapter13/SymmetricOn · SBLocalization.SymmetricStructureOn.restrict`. A structure on N restricts to any $M \leq N$, with the same index set and sections. Equivariance needs that Γ of M is Γ of N on U_M, which is what $\leq$ says. - The structures of Definition 13.2.5 are structures on the neighbourhood given by their domain `Chapter13/SymmetricOn · SBLocalization.SymmetricStructure.toOn`. So by Lemma 13.2.6 they exist at every point `Chapter13/SymmetricOn · SBLocalization.exists_symmetricStructureOn`.

The algebra of structures is §§XIII.11–XIII.13.

XIII.10 Definitions 13.2.7 and 13.2.8 (2017: Definitions 13.9 and 13.10): decorated sc⁺-multisections

Good systems with smaller sets. The decorations need good systems whose neighbourhoods are smaller than a given system's and whose natural actions may be different representations. `Chapter13/DecoratedMultisection · EpGroupoid.GoodSystem.ofSubset`: if $(M(x))$ are neighbourhoods with the natural action, with $U_M(x) \subset U(x)$ for a good system $\mathcal{U}$, then $(M(x))$ is a good system. - Properness passes to closed subsets. - Condition (3) passes to subsets, as in Proposition 13.1.3.

The proof of Proposition 13.1.3 does not use that the representations are the same.

For two good systems there is a third inside both `Chapter13/DecoratedMultisection · EpGroupoid.GoodSystem.exists_subset_inter`. At each x the invariant core of $U_1(x)$ in $U_1(x) \cap U_2(x)$ is a neighbourhood with the natural action of the first system, and the previous lemma applies.

Definition 13.2.7 (same), p. 610 `Chapter13/DecoratedMultisection · SBLocalization.Decoration` `Chapter13/DecoratedMultisection · SBLocalization.DecoratedTuple`. A decoration of an sc⁺-multisection Λ is a pair $(\mathcal{U}, S)$: - $\mathcal{U}$ is a good system; - for every x, $S(x)$ is a symmetric structure of Λ on the neighbourhood $U(x)$.

A decorated tuple is $(\Lambda, \mathcal{U}, S)$ with Λ an sc⁺-multisection. The properness clause of Definition 13.2.5 is Definition 13.1.2 (1), and the natural action is the good system's (§XIII.1).

Existence `Chapter13/DecoratedMultisection · SBLocalization.exists_decoration`. Every sc⁺-multisection over an ep-groupoid with paracompact orbit space has a decoration. 1. At each x take a symmetric structure $S_0(x)$ on a neighbourhood $N(x)$ (Lemma 13.2.6). 2. Theorem 13.1.8 gives a good system $\mathcal{U}_0$ with $U_0(x) \subset U_{N(x)}$. 3. At each x take, by the common refinement lemma of §XIII.9, $M(x) \leq N_0(x)$ and $M(x) \leq N(x)$. On $M(x)$ the actions of the good system and of the structure agree. 4. $(M(x))$ is a good system by the lemma above, and $S_0(x)$ restricts to $M(x)$.

The paracompactness is the text's: the text's §13.2 assumes it through Theorem 13.1.8. It is witnessed as in the intro.

Definition 13.2.8 (same), p. 611 `Chapter13/DecoratedMultisection · SBLocalization.Decoration.Rel`. $(\Lambda, \mathcal{U}, S) \sim (\Lambda', \mathcal{U}', S')$ if: - $\Lambda = \Lambda'$; - there is a good system $\mathcal{U}''$ with $U''(x) \subset U(x) \cap U'(x)$ for all x; - there are G_x-equivariant bijections $b_x : I_x \to I'_x$ with $s'_{b_x(i)} = s_i$ on $U''(x)$.

Equivariance of b_x is with respect to the actions of the two structures. On $U''(x)$ these are the actions of the respective neighbourhoods. The definition does not ask that the two representations agree; the bijection and the sections carry the comparison.

An equivalence relation. - Reflexive with $\mathcal{U}'' = \mathcal{U}$ and the identity `Chapter13/DecoratedMultisection · SBLocalization.Decoration.Rel.refl`. - Symmetric with the inverse bijections `Chapter13/DecoratedMultisection · SBLocalization.Decoration.Rel.symm`. - Transitive `Chapter13/DecoratedMultisection · SBLocalization.Decoration.Rel.trans`: given $\mathcal{U}''_{12}$ and $\mathcal{U}''_{23}$, take a good system inside both (the lemma above) and compose the bijections. On the common system both equalities of sections hold.

So it is an equivalence `Chapter13/DecoratedMultisection · SBLocalization.DecoratedTuple.equivalence`. Its classes are the decorated sc⁺-multisections `Chapter13/DecoratedMultisection · SBLocalization.DecoratedMultisection`, with the map to the underlying functor `Chapter13/DecoratedMultisection · SBLocalization.DecoratedMultisection.forget`, whose image consists of sc⁺-multisections.

XIII.11 Definition 13.2.9 (2017: Definition 13.11) and the remark that there are no inverses: sums

Convolution Chapter13/MultisectionConvolution · SBLocalization.convAt Chapter13/MultisectionConvolution · SBLocalization.conv. For finitely many functions $\Lambda_1, \dots, \Lambda_n : W \to \mathbb{Q}^+$ and $w \in W_x$,

$$(*_i \Lambda_i)(w) = \sum_{(w_1,\dots,w_n)\in W_x^n,\ \sum_i w_i = w} \prod_i \Lambda_i(w_i).$$

The sum is formally over all tuples in the fibre, as a sum with finite support. It is finite when each Λ_i has finite support over x, which is the case for sc⁺-multisections (§XIII.8). The algebra of §13.2 consists of this one operation.

Expansion of a product of sums. If each Λ_i is given on O by a local structure $(s^i_j, \sigma^i_j)_{j\in J_i}$, then for $P(w) \in O$

$$(*_i \Lambda_i)(w) = \sum_{(j_1,\dots,j_n):\sum_i s^i_{j_i}(P(w))=w} \prod_i \sigma^i_{j_i}$$

Chapter13/MultisectionConvolution · SBLocalization.conv_eq_sum_of_isLocalRepOn. 1. Substitute $\Lambda_i(w_i) = \sum_{j:s^i_j=w_i} \sigma^i_j$ into the convolution. 2. Expand the product of sums as a sum over tuples $(j_1, \dots, j_n)$, distributivity over a product of finite sums. 3. Exchange the sums. For a fixed tuple (j_i) the inner sum over (w_i) has the single term $w_i = s^i_{j_i}$, present iff $\sum_i s^i_{j_i} = w$.

A local structure for the convolution Chapter13/MultisectionConvolution · SBLocalization.isLocalRepOn_conv. On O, the sections $\sum_i s^i_{j_i}$, indexed by tuples, are sc⁺ (sums, §XIII.8), and the weights $\prod_i \sigma^i_{j_i}$ are positive and sum to $\prod_i \sum_j \sigma^i_j = 1$.

A functor Chapter13/MultisectionConvolution · SBLocalization.isWFunctor_conv. $\mu(\varphi, \cdot)$ is a linear isomorphism $W_x \to W_{x'}$, so it maps the decompositions of w bijectively to the decompositions of $\mu(\varphi, w)$. Each factor keeps its value, the Λ_i being functors.

An sc⁺-multisection Chapter13/MultisectionConvolution · SBLocalization.isScPlusMultisection_conv. At each point, intersect the domains of local structures of the Λ_i and use the local structure above.

Definition 13.2.9 for functors. The sum $\Lambda' \oplus \Lambda''(w) = \sum_{w'+w''=w} \Lambda'(w')\Lambda''(w'')$ is the text's formula (1) Chapter13/MultisectionAlgebra · SBLocalization.multisectionAdd. It is the convolution of the pair, through the identification of pairs with functions on a two-element set Chapter13/MultisectionAlgebra · SBLocalization.multisectionAdd_eq_conv. - So it is an sc⁺-multisection Chapter13/MultisectionAlgebra · SBLocalization.definition_13_2_9. - Locally it is given by the sections $s'_i + s''_j$ with weights $\sigma'_i\sigma''_j$ on a common domain Chapter13/MultisectionAlgebra · SBLocalization.multisectionAdd_eq_sum_of_isLocalRepOn, which is the text's (2)–(3) at the level of local structures. - *Commutative* for all functions Chapter13/MultisectionAlgebra · SBLocalization.multisectionAdd_comm, by swapping the two summands of a decomposition. - *Associative* on sc⁺-multisections Chapter13/MultisectionAlgebra · SBLocalization.multisectionAdd_assoc. Both sides are sums over decompositions $w = w_1+w_2+w_3$ with weight $\Lambda_1(w_1)\Lambda_2(w_2)\Lambda_3(w_3)$, exchanged as finite sums because the fibre supports are finite. - *The zero multisection is neutral* Chapter13/MultisectionNoInverse · SBLocalization.multisectionAdd_zeroMultisection. In $\Lambda \oplus \Lambda_0(w)$ only the decomposition $w = w + 0$ contributes.

Definition 13.2.9 for decorations (restated), p. 611 Chapter13/DecoratedMultisection · SBLocalization.definition_13_2_9_decorated. Given decorations $(\mathcal{U}', S')$ of Λ' and $(\mathcal{U}'', S'')$ of Λ'', the decoration

of $\Lambda' \oplus \Lambda''$ Chapter13/DecoratedMultisection · SBLocalization.Decoration.add has: - *Neighbourhoods* inside $U'(x) \cap U''(x)$ Chapter13/DecoratedMultisection · SBLocalization.Decoration.add_U_subset, chosen by the common refinement lemma of §XIII.9 so that the actions of $U'(x)$ and $U''(x)$ agree on them Chapter13/DecoratedMultisection · SBLocalization.Decoration.exists_common. They form a good system, by the lemma of §XIII.10. - *Index sets* $I'_x \times I''_x$ with the diagonal action Chapter13/DecoratedMultisection · SBLocalization.Decoration.add_I. - *Sections* $s_{(i,i')} = s'_i + s''_{i'}$ Chapter13/DecoratedMultisection · SBLocalization.Decoration.add_s_apply.

Reading. The text takes $U(x) = U'(x) \cap U''(x)$. The two natural actions on it need not agree. A symmetric structure needs one action for which both families are equivariant, and Definition 13.1.2 needs one natural representation. So $U(x)$ is an open neighbourhood of x inside the intersection on which the two actions agree. The class does not depend on this choice, since Definition 13.2.8 allows shrinking.

The symmetric structure of the sum Chapter13/SymmetricOn · SBLocalization.SymmetricStructureOn.add. - *Sc⁺:* sums of sc⁺-sections. - *Equivariance:* $s'_{gi}(g*y) + s''_{gi'}(g*y) = \mu(\Gamma, s'_i(y)) + \mu(\Gamma, s''_{i'}(y)) = \mu(\Gamma, s'_i(y) + s''_{i'}(y))$, by additivity of $\mu(\psi, \cdot)$. - *The count:* $|I' \times I''|^{-1} \#\{(i,i') : s'_i + s''_{i'} = w\}$ is the expansion of the convolution with weights $|I'|^{-1}|I''|^{-1}$, so it equals $\Lambda' \oplus \Lambda''(w)$.

Well defined on classes Chapter13/DecoratedMultisection · SBLocalization.Decoration.add_rel. If $(\Lambda', \mathcal{U}'_1, S'_1) \sim (\Lambda', \mathcal{U}'_2, S'_2)$ with bijections b'_x on $\mathcal{U}'_{12}$, and likewise for Λ'', then the sums are equivalent. Use a good system inside all four neighbourhood systems and the two common ones, and the product bijections $b'_x \times b''_x$.

So $\oplus$ is defined on decorated sc⁺-multisections Chapter13/DecoratedMultisection · SBLocalization.DecoratedMultisection.add, compatibly with forgetting Chapter13/DecoratedMultisection · SBLocalization.DecoratedMultisection.forget_add. It is commutative Chapter13/DecoratedMultisection · SBLocalization.DecoratedMultisection.add_comm and associative Chapter13/DecoratedMultisection · SBLocalization.DecoratedMultisection.add_assoc there, through the swap bijection $I' \times I'' \to I'' \times I'$ Chapter13/DecoratedMultisection · SBLocalization.Decoration.add_comm_rel and the reassociation bijection of triple products Chapter13/DecoratedMultisection · SBLocalization.Decoration.add_assoc_rel.

The remark after Definition 13.2.9: no inverses (same), p. 611. "Inverse" is read with respect to the neutral element Λ_0, the zero multisection. 1. *The example.* - Take the trivial bundle $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ over the trivial ep-groupoid $\mathbb{R}^n$ Chapter13/MultisectionNoInverse · SBLocalization.NoInverse.A. - For a constant $c \in \mathbb{R}^k$, let Λ_c give weight $\frac{1}{2}$ to the zero section and $\frac{1}{2}$ to the constant section c Chapter13/MultisectionNoInverse · SBLocalization.NoInverse.twoValued. When $c \neq 0$, $\Lambda_c(0) = \Lambda_c(c) = \frac{1}{2}$. - It is an sc⁺-multisection Chapter13/MultisectionNoInverse · SBLocalization.NoInverse.isScPlusMultisection_twoValued, with that two-section local structure everywhere. Constant sections of a trivial bundle are sc⁺. 2. *Two values have total weight at most* 1 Chapter13/MultisectionNoInverse · SBLocalization.NoInverse.add_le_one_of_ne. For an sc⁺-multisection Λ' and $u \neq v$ in one fibre, $\Lambda'(u) + \Lambda'(v) \leq 1$, because the weights over a point sum to 1 (§XIII.8). 3. *No inverse* Chapter13/MultisectionNoInverse · SBLocalization.NoInverse.remark_13_2_9_no_inverse. For $c \neq 0$ and every sc⁺-multisection Λ', $\Lambda_c \oplus \Lambda' \neq \Lambda_0$. - Over $x = 0$, the decompositions $0 = w' + w''$ with $\Lambda_c(w') > 0$ are $w' = 0$ and $w' = c$. - So $(\Lambda_c \oplus \Lambda')(0_x) = \frac{1}{2}\Lambda'(0) + \frac{1}{2}\Lambda'(-c) \leq \frac{1}{2}$, by step 2 with $0 \neq -c$. - But $\Lambda_0(0_x) = 1$. 4. *Such a* Λ_c *exists* when $k \geq 1$ Chapter13/MultisectionNoInverse · SBLocalization.NoInverse.exists_no_inverse, with c the constant vector with all entries 1.

XIII.12 Definition 13.2.10 (2017: Definition 13.12) and Lemma 13.2.11 (2017: Lemma 13.4): multiples and products with functions

Definition 13.2.10 for functors (same), p. 611 `Chapter13/MultisectionAlgebra · SBLocalization.multisectionSmul`. For $a \in \mathbb{R}$: - $(0 \cdot \Lambda)(0_x) = 1$ and $(0 \cdot \Lambda)(w) = 0$ for $w \neq 0_x$; - $(a\Lambda)(w) = \Lambda(a^{-1}w)$ for $a \neq 0$.

Facts: - $0 \cdot \Lambda$ is the zero multisection `Chapter13/MultisectionAlgebra · SBLocalization.multisectionSmul_zero`. - $a\Lambda$ is a functor: $\mu(\varphi, \cdot)$ is linear, so $\mu(\varphi, a^{-1}w) = a^{-1}\mu(\varphi, w)$. - If Λ is given on O by (s_i, σ_i), then $a\Lambda$ is given on O by (as_i, σ_i) `Chapter13/MultisectionAlgebra · SBLocalization.multisectionSmul_eq_sum_of_isLocalRepOn`. - For $a \neq 0$: $as_i(P(w)) = w$ iff $s_i(P(w)) = a^{-1}w$. - For $a = 0$: all sections as_i are 0. The sum of all weights is 1 at $w = 0$ and the empty sum is 0 at $w \neq 0$, which is the zero multisection. - The sections as_i are sc⁺ (constant multiples, §XIII.8). So $a\Lambda$ is an sc⁺-multisection `Chapter13/MultisectionAlgebra · SBLocalization.definition_13_2_10`.

Lemma 13.2.11 for functors (same), p. 612 `Chapter13/MultisectionAlgebra · SBLocalization.lemma_13_2_11`. Let $\beta : X \to \mathbb{R}$ be an sc-smooth functor: sc-smooth on the objects and constant along morphisms, $\beta(t\varphi) = \beta(s\varphi)$. Define $(\beta\Lambda)(w) = (\beta(P(w))\Lambda)(w)$ `Chapter13/MultisectionAlgebra · SBLocalization.multisectionSmulFun`. Then $\beta\Lambda$ is an sc⁺-multisection. 1. *A functor.* For φ with $P(w) = s\varphi$: $(\beta\Lambda)(\mu(\varphi, w)) = (\beta(t\varphi)\Lambda)(\mu(\varphi, w)) = (\beta(s\varphi)\Lambda)(\mu(\varphi, w)) = (\beta(s\varphi)\Lambda)(w)$, using the invariance of β and the functoriality of $\beta(s\varphi)\Lambda$. 2. *Local structure.* Near a point, take (s_i, σ_i) for Λ on O. The sections βs_i are sc⁺ on O (β sc-smooth, §XIII.8). With the weights σ_i they represent $\beta\Lambda$, by the pointwise formula of Definition 13.2.10 at $a = \beta(P(w))$. 3. No case distinction is needed between $\beta \neq 0$ and $\beta = 0$. The local formula of Definition 13.2.10 holds for every a, including 0, and is applied pointwise.

Decorated versions (same). The decoration of $a\Lambda$ `Chapter13/DecoratedMultisection · SBLocalization.Decoration.smul` `Chapter13/DecoratedMultisection · SBLocalization.definition_13_2_10_decorated` keeps the good system and index sets and multiplies the sections by a. - Equivariance is homogeneity of $\mu(\psi, \cdot)$ (§XIII.9). - The count is the local formula above, with all weights $|I_x|^{-1}$. - For $a = 0$ the sections are 0 and the count gives the zero multisection.

The decoration of $\beta\Lambda$ `Chapter13/DecoratedMultisection · SBLocalization.Decoration.smulFun` `Chapter13/DecoratedMultisection · SBLocalization.lemma_13_2_11_decorated` has the sections βs_i. Equivariance of βs_i uses $\beta(g * y) = \beta(y)$, which is the invariance of β along $\Gamma(g, y)$, together with homogeneity of μ.

Both are compatible with Definition 13.2.8 `Chapter13/DecoratedMultisection · SBLocalization.Decoration.smulFun_rel`, with the same bijections. So they are defined on decorated classes `Chapter13/DecoratedMultisection · SBLocalization.DecoratedMultisection.smul`.

XIII.13 Definition 13.2.12 (2017: Definition 13.13) and Lemma 13.2.13 (2017: Lemma 13.5): locally finite sums

Definition 13.2.12 (same), p. 612 `Chapter13/MultisectionLocallyFinite · SBLocalization.IsLocallyFiniteFamily`. A family $(\Lambda_j)_{j \in J}$ of functions $W \to \mathbb{Q}^+$ is locally finite if every x has an open saturated $O(x) \ni x$ for which the set

$$J_{O(x)} = \{j : \exists w \neq 0,\ P(w) \in O(x),\ \Lambda_j(w) > 0\}$$

`Chapter13/MultisectionLocallyFinite · SBLocalization.nontrivIdx` is finite.

The remark after it Chapter13/MultisectionLocallyFinite · SBLocalization.IsLocallyFiniteFamily.exists_stable. $O(x)$ can be chosen so that the index set does not change on smaller open saturated neighbourhoods of x. 1. Among the open saturated $O \ni x$ with J_O finite, choose one whose J_O has the fewest elements, a minimum of natural numbers. 2. For a smaller open saturated $O' \ni x$, $J_{O'} \subset J_O$, and $J_{O'}$ is finite. By minimality it is not smaller, so $J_{O'} = J_O$.

Lemma 13.2.13 for functors (restated), p. 612 Chapter13/MultisectionLocallyFinite · SBLocalization.lemma_13_2_13. The sum of a locally finite family of sc⁺-multisections is an sc⁺-multisection.

The sum written out Chapter13/MultisectionLocallyFinite · SBLocalization.lfSum. The text writes $\bigoplus_{j\in J} \Lambda_j$ without a formula for infinite J. It is read as

$$\Big(\bigoplus_j \Lambda_j\Big)(w) = \sum_{(w_j)\text{ finitely supported},\ \sum_j w_j = w} \prod_j \Lambda_j(w_j),$$

where the product over j is over the finitely many j with $w_j \neq 0$, each other factor $\Lambda_j(0)$ being read as 1 near the point. For finite J this is the convolution of §XIII.11 Chapter13/MultisectionLocallyFinite · SBLocalization.lfSum_eq_conv: a finitely supported family on a finite set is a function, and the identification is a bijection of index sets of the two sums.

Proof. 1. *Trivial members.* For $j \notin J_{O(x)}$ and $y \in O(x)$, Λ_j is trivial at y. Its only positive value over y is at 0_y, with weight 1 (§XIII.8). 2. *Over $O(x)$ the sum is a finite convolution* Chapter13/MultisectionLocallyFinite · SBLocalization.lfSum_eq_conv_of_mem. - In a decomposition (w_j) of w over $y \in O(x)$, every $j \notin J_{O(x)}$ with $w_j \neq 0$ makes the product 0. - So only decompositions supported in the finite set $J_{O(x)}$ contribute, and the factors of the other indices are $\Lambda_j(0) = 1$. - These are exactly the terms of the finite convolution over $J_{O(x)}$. 3. *A functor.* The saturated $O(x)$ contains both ends of every morphism leaving it. Along φ the formula of step 2 is the finite convolution, which is a functor (§XIII.11). 4. *Local structure.* On $O(x)$ the finite convolution has the local structure of §XIII.11, intersected over the finitely many local structures of the Λ_j, $j \in J_{O(x)}$.

Restated: the infinite sum, left implicit in the text, is written out.

Decorated version (restated) Chapter13/DecoratedMultisection · SBLocalization.lemma_13_2_13_decorated. Given decorations $(\mathcal{U}_j, S_j)$ of a locally finite family, and a good system $\mathcal{U}_0$, the decoration of $\bigoplus_j \Lambda_j$ Chapter13/DecoratedMultisection · SBLocalization.Decoration.lfSum has the following data at x. - *Neighbourhood*: inside $O(x) \cap \bigcap_{j\in J_x} U_j(x)$, with $J_x = J_{O(x)}$. It is chosen by the common refinement lemma of §XIII.9 so that the natural actions of $\mathcal{U}_0$ and of all $U_j(x)$, $j \in J_x$, agree on it Chapter13/DecoratedMultisection · SBLocalization.exists_lfData. - *Index set* $\prod_{j\in J_x} I^j_x$, with sections $\sum_{j\in J_x} s^{j,x}_{i_j}$ Chapter13/DecoratedMultisection · SBLocalization.lfSumStructure. - This is the symmetric structure of a finite product Chapter13/SymmetricOn · SBLocalization.SymmetricStructureOn.pi, whose count is the expansion of §XIII.11. - It is then transferred to $\bigoplus_j \Lambda_j$ by step 2 above, since the count formula only depends on Λ through its values on the neighbourhood.

Reading. The intersection is read as for Definition 13.2.9. When $J_x = \emptyset$, the text leaves the natural action on $O(x)$ open. It is taken from $\mathcal{U}_0$, an argument of the construction: any $\mathcal{U}_j$, or Theorem 13.1.8. With $J_x = \emptyset$ the index set is the empty product, a one-point set, and the section is the empty sum 0, which represents the trivial sum.

XIII.14 Definitions 13.3.1 and 13.3.2, Example 13.3.3, Definition 13.3.4 and Remark 13.3.5 (2017: Definitions 13.14 and 13.15, Example 13.1, Definition 13.16, Remark 13.1): correspondences

§13.3 opens with the display (13.5) on p. 613. It names, for two points x, x' with symmetric structures, the finite index sets I_x and $I_{x'}$ that the correspondences relate. The formalization has no separate statement for it. Its content is the setting of Definition 13.3.1.

Definition 13.3.1 (same), p. 613 `Chapter13/Correspondence · SBLocalization.IndexDiagram`. A diagram $I_x \xleftarrow{a} I \xrightarrow{b} I_{x'}$ of finite sets with: - a and b surjective; - all fibres of a of one size; - all fibres of b of one size.

The fibre sizes are compared through cardinalities of subtypes. Two diagrams are equivalent if a bijection $c : I \to I'$ makes both triangles commute `Chapter13/Correspondence · SBLocalization.IndexDiagram.Equiv`. This is an equivalence relation `Chapter13/Correspondence · SBLocalization.IndexDiagram.equivalence`, and $J(x, x')$ is the set of classes, the *correspondences* `Chapter13/Correspondence · SBLocalization.IndexCorr`.

Constructions on classes: - A bijection $e : I_x \to I_{x'}$ gives $[I_x \xleftarrow{\mathrm{id}} I_x \xrightarrow{e} I_{x'}]$. The special case $e : I_x \to I_x$ a permutation by $g \in G_x$ is written $[\mathrm{id}, g]$ `Chapter13/Correspondence · SBLocalization.IndexCorr.ofPerm`. - Relabelling the two outer sets by bijections acts on classes `Chapter13/Correspondence · SBLocalization.IndexCorr.map`. It is well defined because an equivalence c of diagrams is also one of the relabelled diagrams.

Definition 13.3.2 (stronger), p. 614. - *The pseudo-inverse* $\sharp$ reverses a diagram, $[a, b]^\sharp = [b, a]$ `Chapter13/Correspondence · SBLocalization.IndexCorr.swap`. It is an involution `Chapter13/Correspondence · SBLocalization.IndexCorr.swap_swap`, so a bijection $J(x, x') \to J(x', x)$ `Chapter13/Correspondence · SBLocalization.IndexCorr.swapEquiv`. - *The bi-action* is $g' * [a, b] * g = [g^{-1} \circ a, g' \circ b]$ `Chapter13/Correspondence · SBLocalization.IndexCorr.biact`, written as the relabelling by the permutations g^{-1} and g'. - *Stronger*: the text defines the maps; the formalization also proves the action laws, which the text does not state: - $1 * \tau * 1 = \tau$ `Chapter13/Correspondence · SBLocalization.IndexCorr.biact_one_one`; - $g' * (h' * \tau * h) * g = (g'h') * \tau * (hg)$ `Chapter13/Correspondence · SBLocalization.IndexCorr.biact_biact`.

This is an action of $G_{x'} \times G_x^{\mathrm{op}}$, the same shape as the bi-action on morphisms (§XIII.3). It is what Definition 13.3.4 (2) compares with.

Example 13.3.3 (same), p. 614 `Chapter13/Correspondence · SBLocalization.IndexCorr.example_13_3_3`. If $I_x = \{*\}$, then $g' * \tau * g = \tau$ for all g, g'. 1. a is constant, so $g^{-1} \circ a = a$. 2. For $g' \circ b$, build a bijection $c : I \to I$ with $b \circ c = g' \circ b$ fibre by fibre. The fibre $b^{-1}(j)$ and the fibre $b^{-1}(g'^{-1}j)$ have the same size, so there is a bijection between them. Assembling these bijections gives a bijection of I, with $a \circ c = a$ trivially.

Definition 13.3.4 (same), p. 614 `Chapter13/StructurableMultisection · SBLocalization.Decoration.IsCorrespondence`. For a decoration $(\mathcal{U}, S)$ and points x, x', a map τ from morphisms to $J(x, x')$ is a correspondence if on $\mathcal{U}(x, x')$: - (1) it is locally constant and has finitely many values on $\mathcal{U}(x, x')$; - (2) it is equivariant: $\tau(g' * \varphi * g) = g' * \tau(\varphi) * g$, with the bi-action of the good system (§XIII.3) on the left and that of Definition 13.3.2 on the right, for the actions of the symmetric structures on the index sets; - (3) it is compatible with the sections: for every representative $I_x \xleftarrow{a} I \xrightarrow{b} I_{x'}$ of $\tau(\varphi)$, every $k \in I$ and every ψ in the component of φ in $\mathcal{U}(x, x')$,

$$s^{x'}_{b(k)}(t\psi) = \mu(\psi, s^{x}_{a(k)}(s\psi))$$

`Chapter13/StructurableMultisection · SBLocalization.Decoration.Compat`.

τ is a function on all morphisms; only its values on $\mathcal{U}(x, x')$ enter.

Remark 13.3.5 (same), p. 615 `Chapter13/Correspondence · SBLocalization.IndexCorr.sat_iff`. For a relation R on $I_x \times I_{x'}$, "$R(a(k), b(k))$ for all $k \in I$" is invariant under equivalence of diagrams `Chapter13/Correspondence · SBLocalization.IndexDiagram.sat_iff_of_equiv`: the bijection c only renames k. So it is a property of the class `Chapter13/Correspondence · SBLocalization.IndexCorr.Sat`, held by τ iff by one representative iff by every representative. Condition (3) is of this form. The text's remark, that (3) does not depend on the representative, is this lemma.

The saturation property has the expected closure properties, used below: - it passes to products, relabellings and $\sharp$; - it is monotone in R; - it holds for every R that holds everywhere.

XIII.15 Definitions 13.3.6–13.3.11 and Remarks 13.3.7, 13.3.9 (2017: Definitions 13.17–13.20, Remarks 13.2, 13.3): structurable and structured sc⁺-multisections

Definition 13.3.6 (same), p. 615 `Chapter13/StructurableMultisection · SBLocalization.Decoration.Tau`. A *structure* on a decoration $(\mathcal{U}, S)$ is a family of correspondences $\tau_{x,x'}$, for all x, x', with: - (1) $\tau_{x,x}(\Gamma(g, y)) = [\mathrm{id}, g]$ for $y \in U(x)$, $g \in G_x$; - (2) $\tau_{x',x}(\varphi) = \tau_{x,x'}(\varphi^{-1})^\sharp$ for $\varphi \in \mathcal{U}(x', x)$.

A function Λ is *structurable* if it is an sc⁺-multisection and some decoration of it carries a structure `Chapter13/StructurableMultisection · SBLocalization.IsStructurable`. A decorated class is structurable if a representative carries one `Chapter13/StructurableMultisection · SBLocalization.DecoratedMultisection.IsStructurable`. The two notions agree: Λ is structurable iff it underlies a structurable decorated class `Chapter13/StructurableMultisection · SBLocalization.isStructurable_iff`.

The witness, the zero multisection `Chapter13/StructurableMultisection · SBLocalization.isStructurable_zeroMultisection`, over an ep-groupoid with a good system: - at every point the index set $\{*\}$ with the zero section, which is a symmetric structure of the zero multisection; - every $\tau_{x,x'}$ the unit diagram $[\{*\} \leftarrow \{*\} \rightarrow \{*\}]$.

Conditions (1)–(2) hold because, on one-point sets, every correspondence is the unit diagram (Example 13.3.3), and (3) holds because both sides are zero. The good system is from Theorem 13.1.8, so the witness is stated over a paracompact orbit space.

Remark 13.3.7 and Definition 13.3.8 (same), p. 616. The tuples $(\Lambda, \mathcal{U}, S, \tau)$ `Chapter13/StructurableMultisection · SBLocalization.StructuredTuple` are compared `Chapter13/StructurableMultisection · SBLocalization.StructuredTuple.Equiv` as follows. $(\Lambda, \mathcal{U}, S, \tau) \sim (\Lambda', \mathcal{U}', S', \tau')$ if: - $\Lambda = \Lambda'$; - there is a good system $\mathcal{U}''$ with $U''(x) \subset U(x) \cap U'(x)$; - $I_x = I'_x$ for all x; - $\tau = \tau'$ on $\mathcal{U}''(x, x')$.

The equality of index sets is an equality of types, and τ' is compared with τ after transport along it. This is an equivalence relation `Chapter13/StructurableMultisection · SBLocalization.StructuredTuple.equivalence`. For transitivity, use a good system inside both intermediate ones (§XIII.10) and compose the type equalities. Its classes are the *structured sc⁺-multisections* `Chapter13/StructurableMultisection · SBLocalization.StructuredMultisection`.

Reading. As printed, Definition 13.3.8 puts no condition on the sections S, S'. It is formalized as printed. Nothing below uses the sections of an equivalent tuple: every construction on classes is shown independent of the representative through Λ, the good systems and τ. Remark 13.3.7 says the structures are what makes sums well defined; this is §XIII.16.

Remark 13.3.9 (nothing), p. 616: prose on the role of the structures. It has no formal counterpart.

Definition 13.3.10 (same), p. 616: structured sc⁺-multisections are the classes above, and the forgetful map to sc⁺-multisections is $[\Lambda, \mathcal{U}, S, \tau] \mapsto \Lambda$.

Definition 13.3.11 (same), p. 617. - $\Gamma^+_m(P)$, the sc⁺-multisections `Chapter13/StructurableMultisection · SBLocalization.Γm`; - $\Gamma^+_s(P)$, the structurable ones `Chapter13/StructurableMultisection · SBLocalization.Γs`; - $\Gamma^+_{st}(P)$, the structured ones `Chapter13/StructurableMultisection · SBLocalization.Γst`.

$\Gamma^+_s \subset \Gamma^+_m$, and the forgetful map sends Γ^+_{st} onto Γ^+_s `Chapter13/StructurableMultisection · SBLocalization.StructuredMultisection.range_forget`. This is the text's statement that every structurable Λ lifts to a structured one: a structurable Λ has a decoration with a structure, whose class lies over Λ.

XIII.16 Proposition 13.3.12 (2017: Proposition 13.3), Remark 13.3.13 (2017: Remark 13.4) and Lemma 13.3.14 (2017: Lemma 13.6): sums and multiples of structurable sc⁺-multisections

The product of two correspondences `Chapter13/Correspondence · SBLocalization.IndexCorr.prod`. $[a_1, b_1] \times [a_2, b_2] = [a_1 \times a_2, b_1 \times b_2]$, a diagram $I^1_x \times I^2_x \leftarrow I_1 \times I_2 \rightarrow I^1_{x'} \times I^2_{x'}$. - The fibres of a product map are products of fibres `Chapter13/Correspondence · SBLocalization.IndexDiagram.card_fiber_prodMap`, so they have equal sizes. Products of surjections are surjective. - The product is well defined on classes, by the product of the equivalences. - It commutes with $\sharp$ `Chapter13/Correspondence · SBLocalization.IndexCorr.prod_swap`, with the bi-action for the diagonal actions `Chapter13/Correspondence · SBLocalization.IndexCorr.prod_biact`, and with $[\mathrm{id}, g]$ `Chapter13/Correspondence · SBLocalization.IndexCorr.prod_ofPerm`. - A product saturates the product relation when each factor saturates its relation.

Proposition 13.3.12 (restated), p. 617 `Chapter13/StructurableMultisection · SBLocalization.proposition_13_3_12`. The sum of two structurable sc⁺-multisections is structurable.

Proof. 1. *"We may assume $\mathcal{U}_1 = \mathcal{U}_2$."* Let Λ_1, Λ_2 carry structures τ^1, τ^2 over decorations $(\mathcal{U}_1, S_1)$, $(\mathcal{U}_2, S_2)$. The decorated sum (§XIII.11) has neighbourhoods $M(x)$ with $M(x) \leq N_1(x)$ and $M(x) \leq N_2(x)$. - Both structures restrict to the decorations on $(M(x))$ `Chapter13/StructurableMultisection · SBLocalization.Decoration.Tau.restrict`. - On smaller neighbourhoods, $\mathcal{U}_M(x, x') \subset \mathcal{U}_i(x, x')$ and the components are smaller, so local constancy and compatibility restrict. - The bi-action does not change on a smaller neighbourhood with the same action `Chapter13/StructurableMultisection · EpGroupoid.GoodSystem.biact_congr_of_le`, because it is built from the Γ's, which agree there. So equivariance restricts. - The diagonal condition (1) holds because Γ is the same. 2. *The structure of the sum* `Chapter13/StructurableMultisection · SBLocalization.Decoration.Tau.prod` `Chapter13/StructurableMultisection · SBLocalization.Decoration.Tau.add` is $\tau = \tau^1 \times \tau^2$ on the index sets $I^1_x \times I^2_x$ with sections $s^1_i + s^2_j$. - *Local constancy:* both factors are locally constant near φ. - *Finiteness:* the values lie in the product of two finite sets of values. - *Equivariance:* factorwise, through the product lemma for the bi-action. - *(1) and (2) of Definition 13.3.6:* factorwise, through the product lemmas for $[\mathrm{id}, g]$

and ♯. - *Compatibility (3):* the text's computation. For representatives with $s^1_{b_1(k)} = \mu(\psi, s^1_{a_1(k)})$ and $s^2_{b_2(l)} = \mu(\psi, s^2_{a_2(l)})$, $\mu(\psi, s^1_{a_1(k)} + s^2_{a_2(l)}) = s^1_{b_1(k)} + s^2_{b_2(l)}$, by additivity of $\mu(\psi, \cdot)$ (§XIII.9). 3. For structured tuples the sum is again a structured tuple `Chapter13/StructurableMultisection · SBLocalization.StructuredTuple.add`, over $\Lambda_1 \oplus \Lambda_2$ `Chapter13/StructurableMultisection · SBLocalization.StructuredTuple.add_Λ`.

Restated: "we may assume $\mathcal{U}_1 = \mathcal{U}_2$" is carried out by restriction to the neighbourhoods of the decorated sum, on which the two natural actions agree.

Remark 13.3.13 (narrower), p. 618. The structured sums $\Lambda_1 \oplus \Lambda_2$ and $\Lambda_2 \oplus \Lambda_1$ have the same underlying functor. This is `StructuredTuple.add_Λ` with the commutativity of §XIII.11. The remark's negative half is that the two differ as structured classes, since the index sets are $I^1_x \times I^2_x$ and $I^2_x \times I^1_x$. That is a statement that two types are unequal, and it has no formal statement (§XIII.31).

Lemma 13.3.14 (same), p. 618 `Chapter13/StructurableMultisection · SBLocalization.lemma_13_3_14` `Chapter13/StructurableMultisection · SBLocalization.lemma_13_3_14_fun`. If Λ is structurable, so is $r\Lambda$ for every $r \in \mathbb{R}$, including 0, and so is $\beta\Lambda$ for every sc-smooth functor β. - The same τ serves `Chapter13/StructurableMultisection · SBLocalization.Decoration.Tau.smul` `Chapter13/StructurableMultisection · SBLocalization.Decoration.Tau.smulFun`, on the decorations of §XIII.12. - Compatibility (3) is homogeneity: $\mu(\psi, rs_{a(k)}) = r\mu(\psi, s_{a(k)}) = rs_{b(k)}$. - For β, additionally $\beta(t\psi) = \beta(s\psi)$. - Conditions (1), (2) and equivariance do not involve the sections.

XIII.17 The construction before Proposition 13.3.15, Proposition 13.3.15, Remark 13.3.16, Definition 13.3.17 and Corollary 13.3.18 (2017: Proposition 13.4, Remark 13.5, Definition 13.21, Corollary 13.1): tight structures

The trivial set T_Λ `Chapter13/TightMultisection · SBLocalization.trivialSet`. The set of points y that have an open neighbourhood on which Λ is trivial (Definition 13.2.4). - It is open `Chapter13/TightMultisection · SBLocalization.isOpen_trivialSet`. - Λ is trivial on it `Chapter13/TightMultisection · SBLocalization.isTrivialOn_trivialSet`. - Triviality at $s(\psi)$ and at $t(\psi)$ are the same: $\Lambda(0_{t\psi}) = \Lambda(\mu(\psi, 0_{s\psi})) = \Lambda(0_{s\psi})$, Λ being a functor `Chapter13/TightMultisection · SBLocalization.apply_fiberZero_tgt`. For a neighbourhood, transport by a sheet of t.

The construction (stronger), pp. 618–619. Let $(\Lambda, \mathcal{U}, S, \tau)$ be a structured tuple. 1. *Neighbourhoods.* For $x \in T_\Lambda$, shrink $U(x)$ to a neighbourhood with the same action inside $U(x) \cap T_\Lambda$ `Chapter13/TightMultisection · SBLocalization.Decoration.exists_tightNbhd` `Chapter13/TightMultisection · SBLocalization.Decoration.tightNbhd`. This is the common refinement lemma of §XIII.9 with an empty family and $V = T_\Lambda$. For $x \notin T_\Lambda$ keep $U(x)$. 2. *Index sets.* One type that is $\{*\}$ when $x \in T_\Lambda$ and I_x otherwise `Chapter13/TightMultisection · SBLocalization.TightIdx`: the sum of $\{*\}$ restricted to "$x \in T_\Lambda$" and I_x restricted to "$x \notin T_\Lambda$". There are bijections $\{*\} \simeq I'_x$ when $x \in T_\Lambda$ `Chapter13/TightMultisection · SBLocalization.TightIdx.eT` and $I_x \simeq I'_x$ when $x \notin T_\Lambda$ `Chapter13/TightMultisection · SBLocalization.TightIdx.eN`. The text's equalities $I'_x = \{*\}$, $I'_x = I_x$ are these bijections. The G_x-action and the sections are carried along them: the zero section on $\{*\}$, the old ones on I_x. Counts are invariant under such relabelling. 3. *The decoration* `Chapter13/TightMultisection · SBLocalization.Decoration.tight`. On $\{*\}$ the zero section represents Λ on $U'(x) \subset T_\Lambda$, because Λ is trivial there. 4. *The correspondences* `Chapter13/TightMultisection · SBLocalization.Decoration.tightτ`, by the four cases for (x, x'): - both in T_Λ: the unit diagram, relabelled; - $x \in T_\Lambda$,

$x' \notin T_\Lambda$: $[\{*\} \leftarrow I_{x'} \xrightarrow{\mathrm{id}} I_{x'}]$, relabelled `Chapter13/TightMultisection · SBLocalization.Decoration.tightτ_TN`; - $x \notin T_\Lambda$, $x' \in T_\Lambda$: $[I_x \xleftarrow{\mathrm{id}} I_x \to \{*\}]$, relabelled; - neither: the old $\tau_{x,x'}$, relabelled by e_x, $e_{x'}$ `Chapter13/TightMultisection · SBLocalization.Decoration.tightτ_NN`.

It is again structured (stronger) `Chapter13/TightMultisection · SBLocalization.Decoration.Tau.tight`. 1. *Constant correspondences are correspondences*, as far as (1)–(2) of Definition 13.3.4 go `Chapter13/TightMultisection · SBLocalization.Decoration.isCorrespondence_const`. A constant is locally constant with one value. For equivariance, a diagram with one outer set a point and the other mapped by the identity is fixed by the bi-action, by Example 13.3.3 and its mirror image. 2. *Relabelling commutes with $\sharp$ and the bi-action* `Chapter13/TightMultisection · SBLocalization.IndexCorr.swap_map` `Chapter13/TightMultisection · SBLocalization.IndexCorr.biact_map`, so the case "neither" inherits (1)–(2) and conditions (1)–(2) of Definition 13.3.6 from τ. Relabelling the unit diagram by $\{*\} \simeq I'_x$ commutes with permutations. 3. *Compatibility (3)* is the step the text does not check. At a morphism ψ in a component of $\mathcal{U}'(x,x')$ with $x \in T_\Lambda$ or $x' \in T_\Lambda$: - $s\psi \in U'(x)$ and $t\psi \in U'(x')$, and one of these lies in T_Λ. Triviality passes along ψ, so $\Lambda(0) = 1$ at both ends. - Every section of a symmetric structure vanishes where $\Lambda(0_y) = 1$ (§XIII.9). So all sections at both ends are 0 at the relevant points. - Both sides of (3) are 0, since $\mu(\psi, 0) = 0$. 4. *Diagonal (1) of Definition 13.3.6* for $x \in T_\Lambda$: $[\mathrm{id}, g]$ on a point is the unit diagram. For $x \notin T_\Lambda$ it is τ's, relabelled.

Proposition 13.3.15 (restated), p. 619 `Chapter13/TightMultisection · SBLocalization.proposition_13_3_15`. From a structured representative $(\Lambda, \mathcal{U}, S, \tau)$ one gets a structured $(\Lambda, \mathcal{U}', S', \tau')$ with: - (1) for $x \in T_\Lambda$: $I'_x = \{*\}$ with the zero section, and $U'(x) \subset T_\Lambda$ with the action of $U(x)$; - (2) for $x \notin T_\Lambda$: $U'(x) = U(x)$, and equivariant bijections $e_x : I_x \to I'_x$ with $s'_{e_x(i)} = s_i$; - (3) τ' is τ relabelled by e_x, $e_{x'}$, for $x, x' \notin T_\Lambda$; - (4)–(5) the unit-type diagrams otherwise.

It is the construction above `Chapter13/TightMultisection · SBLocalization.Decoration.isTight_tight`. Condition (3) holds for all morphisms, not only on $\mathcal{U}'(x,x')$. *Restated*: the equalities of index sets are the bijections of step 2.

Remark 13.3.16 (nothing), p. 619: prose. No formal counterpart.

Definition 13.3.17 (same), p. 620 `Chapter13/TightMultisection · SBLocalization.Decoration.IsTight` `Chapter13/TightMultisection · SBLocalization.StructuredMultisection.IsTight`. A structured representative is tight if: - (1) $I_x = \{*\}$ with the zero section for $x \in T_\Lambda$; - (2) $\tau_{x,x'}$ is $[* \leftarrow I_{x'} \xrightarrow{\mathrm{id}} I_{x'}]$, resp. $[I_x \xleftarrow{\mathrm{id}} I_x \to *]$, when exactly one of x, x' lies in T_Λ; - (3) $[\{*\} \leftarrow \{*\} \to \{*\}]$ when both do.

"$I_x = \{*\}$" is a bijection $\{*\} \simeq I_x$, and (2)–(3) are stated for every such bijection. All are equal, since a one-point set has one bijection to a given one-point set. A structured class is tight if one representative is.

Corollary 13.3.18 (same), p. 620 `Chapter13/TightMultisection · SBLocalization.corollary_13_3_18` `Chapter13/TightMultisection · SBLocalization.corollary_13_3_18_structured`. Every structurable Λ has a tightly structured version, and every element of Γ_s^+ underlies a tightly structured class. This is Proposition 13.3.15 applied to a structure of Λ.

XIII.18 Proposition 13.3.19 (2017: Proposition 13.5): locally finite sums of structurable sc⁺-multisections

The text proves Proposition 13.3.19 (p. 620) in a paragraph, and leaves to the reader the check that the product of infinitely many correspondences is well defined. The formalization writes that check out. It needs three tools: products of families of correspondences, tight versions over a common good system, and the bookkeeping that near two given points only finitely many factors are not the unit.

Products of families of correspondences `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.pi`. Let $(\tau^l)_{l\in L}$ be correspondences, $\tau^l \in J(I^l, I'^l)$. - *On diagrams* `Chapter13/PiCorrespondence · SBLocalization.IndexDiagram.pi`, the product of $I^l \xleftarrow{a_l} M^l \xrightarrow{b_l} I'^l$ is $\prod_l I^l \leftarrow \prod_l M^l \to \prod_l I'^l$. It is a diagram when $\prod_l M^l$ is finite. The fibres of a product map are products of fibres, so all fibres have one size `Chapter13/PiCorrespondence · SBLocalization.IndexDiagram.card_fiber_pi`. - *On classes*, the product is taken through chosen representatives `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.out`. Any family of representatives gives the same class `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.pi_eq_mk`: the product of the equivalences is an equivalence. So equal factors give equal products `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.pi_congr`. - *Finiteness.* A product of finite types that are one-point outside a finite set is finite `Chapter13/PiCorrespondence · SBLocalization.finite_pi_of_subsingleton`. A correspondence equal to a diagram with one-point middle set has one-point middle set in its chosen representative `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.subsingleton_out_I`, since equivalent diagrams have bijective middle sets. - *Laws.* - The product saturates the conjunction of relations when every factor saturates its relation `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.sat_pi`. - It commutes with $\sharp$ `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.swap_pi` and with the bi-action of the isotropy groups acting factorwise `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.biact_pi`. - The product of the diagrams $[\mathrm{id}, g]$ is $[\mathrm{id}, g]$ for the product action `Chapter13/PiCorrespondence · SBLocalization.IndexCorr.pi_ofPerm`. - *Reindexing.* A symmetric structure can be relabelled along an equivariant bijection of index sets `Chapter13/PiCorrespondence · SBLocalization.SymmetricStructureOn.reindex`. - *Additivity.* $\mu(\psi, \cdot)$ is additive over finite sums of vectors `Chapter13/PiCorrespondence · SBLocalization.fibAct_sum`.

Tight versions over a given good system. The tight version of §XIII.17 lives on the decoration's own good system. The sum needs tight versions of all members over one common good system. A good system $\mathcal{U}$ is *adapted* to a structured decoration $(\mathcal{U}_\Lambda, S, \tau)$ of Λ `Chapter13/TightOn · SBLocalization.Decoration.IsAdapted` if: - $U(x) \subset T_\Lambda$ for $x \in T_\Lambda$; - for $x \notin T_\Lambda$, the neighbourhood $U(x)$ is $\leq U_\Lambda(x)$, the same action on a smaller set.

Over an adapted system: - *The tight structure* `Chapter13/TightOn · SBLocalization.SymmetricStructureOn.tightRel` has index set $\{*\}$ with the zero section at $x \in T_\Lambda$, and I_x with the restricted sections at $x \notin T_\Lambda$. The decoration is `Chapter13/TightOn · SBLocalization.Decoration.tightOn`. - *The correspondences* `Chapter13/TightOn · SBLocalization.Decoration.tightOnτ` are the given τ between points outside T_Λ, and the unit-type diagrams otherwise, as in §XIII.17. They form a structure `Chapter13/TightOn · SBLocalization.Decoration.Tau.tightOn` by the argument of §XIII.17. Compatibility at the trivial points is again the vanishing of all sections where $\Lambda(0) = 1$. - *It is tight* (Definition 13.3.17) `Chapter13/TightOn · SBLocalization.Decoration.isTight_tightOn`.

The data of the proof `Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData` consist of: - the members Λ_l, $l \in L$, sc⁺-multisections; - the local finiteness of Definition 13.2.12; - decorations $(\mathcal{U}^l, S^l)$ with structures τ^l; - a good system $\mathcal{U}_0$, which provides the natural actions at points where no member is

nontrivial.

The index type L lives in the universe of the bundle.

The common good system. 1. $O(x)$ *and* $F(x)$ Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.O Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.F. For each x, $O(x)$ is the open saturated set of Definition 13.2.12. $F(x)$ is the finite set of members nontrivial over $O(x)$; it contains the text's J_x. For $l \notin F(x)$, $O(x) \subset T_{\Lambda_l}$ Chapter13/LocallyFiniteStructurable · SBLocalization.subset_trivialSet_of_not_mem_nontrivIdx: an open set over which no $w \neq 0$ has positive weight is a set on which Λ_l is trivial (§XIII.8). 2. $V(x)$ Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.V. $V(x) = O(x) \cap \bigcap_{l\in F(x),\, x\in T_{\Lambda_l}} T_{\Lambda_l}$, open, containing x. This is the text's "$V(x) \subset T_l$". 3. $M(x)$ Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.exists_M Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.M. A neighbourhood with the representation of $\mathcal{U}_0$ at x, inside $V(x)$, with $M(x) \leq U_0(x)$ and $M(x) \leq U^l(x)$ for all $l \in F(x)$. This is the common refinement lemma of §XIII.9 for the finitely many $U^l(x)$, $l \in F(x)$. It is the text's $U(x) = V(x) \cap \bigcap_{l\in J_x} U^l(x)$, shrunk so that the natural actions agree. 4. *The good system* Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.□ is $(M(x))$, by the lemma of §XIII.10 applied inside $\mathcal{U}_0$. 5. *Adapted to every member* Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.isAdapted. These are properties (3)–(4) of the text's proof. - If $x \in T_{\Lambda_l}$: either $l \in F(x)$, and $M(x) \subset V(x) \subset T_{\Lambda_l}$ by step 2; or $l \notin F(x)$, and $M(x) \subset O(x) \subset T_{\Lambda_l}$ by step 1. - If $x \notin T_{\Lambda_l}$: then $l \in F(x)$, by step 1, and $M(x) \leq U^l(x)$ by step 3. 6. *Tight versions* Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.Dt Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.tt of all members over $\mathcal{U}$. For $l \notin F(x)$, the tight index set at x is a point and its section is 0.

The symmetric structure of the sum. 1. *The index set* $K_x = \prod_{l\in L} K_x^l$, with K_x^l the tight index set of Λ_l at x Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.K. It is finite Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.finite_K: all factors with $l \notin F(x)$ are points. 2. *The base structure* Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.baseS is the locally finite sum structure of §XIII.13 over the finite set $F(x)$, with index set $\prod_{l\in F(x)} K_x^l$. 3. *Restriction to $F(x)$ is a bijection* $K_x \to \prod_{l\in F(x)} K_x^l$ Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.res_bijective. It is injective because the other factors are points, and surjective by extending with the unique point. 4. *The structure s^x* Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.Sx is the base structure relabelled along that bijection. The decoration of $\bigoplus_l \Lambda_l$ is $(\mathcal{U}, s)$ Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.Dsum. 5. *The text's formula* Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.Sx_s_apply: $s_k^x(y) = \sum_{l\in T} s_{k(l)}^{l,x}(y)$ for every finite $T \supset F(x)$. The terms with $l \notin F(x)$ are zero sections Chapter13/LocallyFiniteStructurable · SBLocalization.tightIdx_elim_zero. This independence of T is what the compatibility below needs: at a morphism from $U(x)$ to $U(x')$ both structures are written over $T = F(x) \cup F(x')$.

The correspondences. 1. *Unit factors.* For $l \notin F(x) \cup F(x')$, both x and x' lie in T_{Λ_l}, so $\tau_{x,x'}^l$ is the relabelled unit diagram, the same for every morphism Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.τ_TT. 2. *The product is defined* Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.finite_out. The middle sets of the chosen representatives are points outside the finite $F(x) \cup F(x')$, so their product is finite. 3. *The correspondence* $\tau_{x,x'}(\varphi) = \prod_{l\in L} \tau_{x,x'}^l(\varphi)$ Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.τ. It depends only on the finitely many factors in $F(x) \cup F(x')$ Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.τ_congr.

Definition 13.3.4 for the product Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.

isCorrespondence. 1. *Locally constant.* Each of the finitely many relevant factors is locally constant near φ, so they are simultaneously constant near φ, and the product is too. 2. *Finitely many values.* If $\mathcal{U}(x, x')$ is empty there is nothing to show. Otherwise the tuple of relevant factors takes values in a finite product of finite sets. The product correspondence is a function of that tuple, so it takes finitely many values. 3. *Equivariance.* Factorwise, by the product law for the bi-action. 4. *Compatibility.* The product of the factors' saturations saturates the conjunction (the product law for saturation). Given the conjunction for indices k, k', the sum formula with $T = F(x) \cup F(x')$ and additivity of $\mu(\psi, \cdot)$ give $s^{x'}_{k'}(t\psi) = \sum_l s^{l,x'}_{k'(l)}(t\psi) = \sum_l \mu(\psi, s^{l,x}_{k(l)}(s\psi)) = \mu(\psi, s^{x}_{k}(s\psi))$.

Definition 13.3.6 for the product Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.tau. - *Diagonal:* the product of $[\mathrm{id}, g]$ is $[\mathrm{id}, g]$. - *Swap:* the product of the swaps is the swap of the product; the finiteness of the swapped product is again by the unit factors.

This is the step left to the reader.

Proposition 13.3.19 (restated), p. 620 Chapter13/LocallyFiniteStructurable · SBLocalization.proposition_13_3_19. For a nonempty family of structurable sc⁺-multisections, locally finite in the sense of Definition 13.2.12, the sum $\bigoplus_l \Lambda_l$ is structurable. The data above give the structure Chapter13/LocallyFiniteStructurable · SBLocalization.LFStructData.isStructurable, with Lemma 13.2.13 for the sc⁺-multisection property. For a nonempty family the good system $\mathcal{U}_0$ is taken from any member's structure. - For any family, including the empty one, given a good system Chapter13/LocallyFiniteStructurable · SBLocalization.proposition_13_3_19_of_goodSystem. - For any family over a paracompact $|X|$, through Theorem 13.1.8 Chapter13/LocallyFiniteStructurable · SBLocalization.proposition_13_3_19_of_paracompact.

The sum over the empty family is the zero multisection, which is structurable exactly when a good system exists, as Definition 13.3.6 requires. *Added hypothesis*: for the empty family, the existence of a good system. It is not derived from the text, it is necessary, and its witness is Theorem 13.1.8.

Locally finite domain supports Chapter13/LocallyFiniteSupports · SBLocalization.isLocallyFiniteFamily_of_locallyFinite. The text's hypothesis is that the domain supports form a locally finite family of subsets of X. It implies Definition 13.2.12 for families of functors. 1. For x take an open $V \ni x$ meeting finitely many dom-supp(Λ_l), and $O = \pi^{-1}(\pi(V))$. It is open by Proposition 7.1.8 (Part VII), and saturated. 2. Suppose $\Lambda_l(w) > 0$ for some $w \neq 0$ over $y \in O$. Choose a morphism $\varphi : y \to v$ with $v \in V$. 3. $\mu(\varphi, w) \neq 0$ Chapter13/LocallyFiniteSupports · SBLocalization.μ_ne_fiberZero_lf, since $\mu(\varphi, \cdot)$ is a linear isomorphism. Also $\Lambda_l(\mu(\varphi, w)) = \Lambda_l(w) > 0$. 4. So $v \in$ dom-supp$(\Lambda_l) \cap V$, and l is one of the finitely many indices.

The saturation of the domain supports is not needed. So Proposition 13.3.19 holds with the hypothesis as printed Chapter13/LocallyFiniteSupports · SBLocalization.proposition_13_3_19_locallyFinite, and for any family over a paracompact $|X|$ Chapter13/LocallyFiniteSupports · SBLocalization.proposition_13_3_19_locallyFinite_of_paracompact.

Restated: the index sets K_x are products of types relabelled by a bijection, and the structure is built over one adapted good system rather than "the same $\mathcal{U}$" the text takes. "Locally finite" is proved from the printed hypothesis.

XIII.19 Theorem 13.4.1 (2017: Theorem 13.3): pull-back along a strong bundle equivalence

The common data of a pull-back `Chapter13/StrongBundlePullMap · SBLocalization.PullMap`. Both Theorem 13.4.1 and Theorem 13.4.4 pull local sc⁺-section structures back along a map $\Phi : W \to W'$ covering a functor $F : X \to X'$. What the two proofs use of Φ is the same: - Φ commutes with the actions: $\Phi(\mu(\varphi, w)) = \mu'(F(\varphi), \Phi(w))$; - every point has an open neighbourhood over which Φ is a strong bundle isomorphism onto its image, over a local sc-diffeomorphism of the bases; - F is faithful: two morphisms with the same source, the same target and the same image agree.

Instances: - A strong bundle equivalence (Definition 10.4.1, Part X) gives such data `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.ofEquivalence`. Its base is an equivalence, faithful by definition. - A proper strong bundle covering, 2021 Definition 8.5.9, gives such data `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.ofCovering`. Faithfulness comes from Definition 8.5.1 (3): the map $\varphi \mapsto (F(\varphi), s(\varphi))$ is an sc-diffeomorphism onto the fibred product, so injective.

Consequences of the data. - $P'(\Phi(w)) = F(P(w))$. - On fibres, Φ is a linear homeomorphism $W_y \to W'_{F(y)}$ `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.fiberEquiv`. It is injective on fibres `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.eq_of_obj_eq`. - F is a local sc-diffeomorphism on objects `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.isLocalScDiffeo_obj`. - Φ intertwines the actions in the total form of §XIII.9 `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.obj_fibAct`.

Pulled-back sections `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.pullSec`: $z \mapsto \Phi_z^{-1}(s'(F(z)))$, with Φ_z the fibre map. For an sc⁺-section s' on U' and an open U with $F(U) \subset U'$, it is an sc⁺-section on U `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.isScPlusSectionOn_pullSec`: near each point it is s' composed with a local strong bundle isomorphism and the local sc-diffeomorphism F. It satisfies $\Phi(\text{pull } s'(z)) = s'(F(z))$, and pull $s'(z) = w$ iff $s'(F(z)) = \Phi(w)$ `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.pullSec_eq_iff`.

The pulled-back functor $\Phi^*\Lambda' = \Lambda' \circ \Phi$ `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.pull` is a functor `Chapter13/StrongBundlePullMap · SBLocalization.PullMap.isWFunctor_pull`: $\Lambda'(\Phi(\mu(\varphi, w))) = \Lambda'(\mu'(F\varphi, \Phi w)) = \Lambda'(\Phi w)$.

$\Phi^*\Lambda'$ is an sc⁺-multisection `Chapter13/MultisectionPullback · SBLocalization.PullMap.isScPlusMultisection_pull`. A local structure (s'_i, σ_i) of Λ' on $O' \ni F(x)$ pulls back to $(\text{pull } s'_i, \sigma_i)$ on $F^{-1}(O')$ `Chapter13/MultisectionPullback · SBLocalization.PullMap.exists_isLocalRepOn_pull`. By the last property of pulled-back sections, pull $s'_i(P(w)) = w$ iff $s'_i(F(P(w))) = \Phi(w)$, so the counts agree.

Adapted neighbourhoods `Chapter13/MultisectionPullback · SBLocalization.PullMap.IsPullNbhd`. For a neighbourhood N' of $F(x)$ with the natural action, a neighbourhood N of x is adapted if: - F is injective on U; - $F(U) \subset U'$; - $F(\Gamma(g, z)) = \Gamma'(F(g), F(z))$ for $z \in U$, with $F(g) \in G'_{F(x)}$ the image of g under the isotropy homomorphism.

Then $F(g * z) = F(g) * F(z)$ `Chapter13/MultisectionPullback · SBLocalization.PullMap.IsPullNbhd.Φ_eq`, applying t to the identity.

Existence inside every open $V \ni x$, with the properness property `Chapter13/MultisectionPullback · SBLocalization.PullMap.exists_isPullNbhd`. 1. F is a local sc-diffeomorphism at x: there is an open $U_0 \ni x$ on which it is injective with a local inverse. 2. Let $O = V \cap U_0 \cap F^{-1}(U')$ and N_0 a neighbourhood of x with the natural action and proper closure inside O (§XIII.1). 3. Let E be the set of $y \in U_0(N_0)$ with $F(\Gamma(g, y)) =$

$\Gamma'(F(g), F(y))$ for all g. - For each g, the two sides are continuous lifts of $y \mapsto F(y)$ through s: both have source $F(y)$. - Two continuous lifts through the local homeomorphism s agree on an open set `Chapter13/StrongBundlePullMap · EpGroupoid.isOpen_setOf_eq_of_src`. - E is a finite intersection of such sets, so open. It contains x, since $\Gamma(g, x)$ is g and F maps it to $F(g)$. 4. Restrict N_0 to its invariant core in E (§XIII.1). Properness passes to the closed subset.

The text arranges $F(U(x)) = U'(F(x))$ "without loss of generality". The inclusion with injectivity is all that is used.

Adapted good systems `Chapter13/MultisectionPullback · SBLocalization.PullMap.PullData` `Chapter13/MultisectionPullback · SBLocalization.PullMap.exists_pullData`. For a good system $\mathcal{U}'$ of X' and open sets $V(x)$, there is a good system of X with $U(x) \subset V(x)$ and each $N(x)$ adapted to $N'(F(x))$. - Properness is from the existence lemma. - Condition (3) is the text's argument `Chapter13/MultisectionPullback · SBLocalization.PullMap.isDiffeoComponent_of_isPull`. 1. F maps $\mathcal{U}(x, x')$ into $\mathcal{U}'(F(x), F(x'))$ `Chapter13/MultisectionPullback · SBLocalization.PullMap.mem_morBetween`, and maps components into components `Chapter13/MultisectionPullback · SBLocalization.PullMap.mapsTo_connectedComponentIn`, by continuity. 2. Let ψ_1, ψ_2 in a component Σ have the same source. Their images lie in one component of $\mathcal{U}'$, where s is injective, so $F(\psi_1) = F(\psi_2)$. 3. Then $F(t\psi_1) = F(t\psi_2)$, so $t\psi_1 = t\psi_2$ by injectivity of F on $U(x')$. 4. Faithfulness gives $\psi_1 = \psi_2$. The same for t. - No paracompactness is used: the system is built point by point, and the good-system conditions are checked directly.

F intertwines the bi-actions `Chapter13/MultisectionPullback · SBLocalization.PullMap.IsPullNbhd.mor_biact`: $F(g' * \varphi * g) = F(g') * F(\varphi) * F(g)$, from the identity for Γ and functoriality.

The pulled-back structure. Let $(\Lambda', \mathcal{U}', S', \tau')$ be a structured tuple and take an adapted good system. - *Index sets* $I_x = I'_{F(x)}$, with G_x acting through $F : G_x \to G'_{F(x)}$. - *Sections* pull $s_i'^{F(x)}$ on $U(x)$. The symmetric structure is `Chapter13/MultisectionPullback · SBLocalization.PullMap.pullStructure`, and the decoration `Chapter13/MultisectionPullback · SBLocalization.PullMap.pullDecoration`. - Equivariance: apply Φ^{-1} to the equivariance of s' at $F(g)$, with $F(g*z) = F(g)*F(z)$ and $\Phi\mu = \mu'\Phi$. - Count: the count of s' at $\Phi(w)$. - *Correspondences* $\tau_{x,y}(\varphi) = \tau'_{F(x),F(y)}(F(\varphi))$ `Chapter13/MultisectionPullback · SBLocalization.PullMap.pullTau`. - Local constancy and finiteness come from those of τ', through the continuity of F and the inclusion $F(\mathcal{U}(x, y)) \subset \mathcal{U}'(F(x), F(y))$. - Equivariance: the bi-action on correspondences for actions through a homomorphism is the bi-action of the images `Chapter13/MultisectionPullback · SBLocalization.PullMap.biact_compHom`. With the intertwining of the bi-actions on morphisms, it is that of τ'. - The diagonal $[\mathrm{id}, g]$ for the action through F is $[\mathrm{id}, F(g)]$ `Chapter13/MultisectionPullback · SBLocalization.PullMap.ofPerm_compHom`. - Compatibility: Φ^{-1} applied to that of τ', since F maps components into components. - The structured tuple is `Chapter13/MultisectionPullback · SBLocalization.PullMap.pullTuple`, so $\Phi^*\Lambda'$ is structurable `Chapter13/MultisectionPullback · SBLocalization.PullMap.isStructurable_pull`.

Canonicity `Chapter13/MultisectionPullback · SBLocalization.PullMap.pullTuple_equiv`. Equivalent structured tuples, pulled back over any two adapted good systems, give equivalent tuples. 1. Take an adapted good system inside both pulled-back systems and adapted to the common system of the two given tuples. 2. On it the index sets are equal, $I'_{F(x)}$ for both, and the correspondences agree because the given ones agree on the common system and F maps into it.

So the pull-back is a map of structured classes `Chapter13/MultisectionPullback · SBLocalization.PullMap.pullStructured` `Chapter13/MultisectionPullback · SBLocalization.PullMap.pullStructured_mk`, over the pull-back of functors `Chapter13/MultisectionPullback · SBLocalization.PullMap.forget_pullStructured`.

Theorem 13.4.1 (stronger), pp. 621–622 `Chapter13/MultisectionPullback · SBLocalization.theorem_13_4_1` `Chap-`

ter13/MultisectionPullback · SBLocalization.theorem_13_4_1_structured. For a strong bundle equivalence Φ over the equivalence F: - $\Phi^*\Lambda'$ is structurable when Λ' is; - there is a map of structured classes over Φ^*, given on every representative and every adapted good system by the pulled-back structure:

$$I_x = I'_{F(x)}, \qquad \Phi(s_i^x(z)) = s_i'^{F(x)}(F(z)), \qquad \tau_{x,y}(\varphi) = \tau'_{F(x),F(y)}(F(\varphi)).$$

Stronger: the text's "canonical way" is read as this map. Its independence of all choices is asserted in the text and proved here. No hypothesis is added; paracompactness is not used.

XIII.20 Charts along a morphism: the tool of Proposition 13.4.2 and Theorem 13.4.3

Proposition 13.4.2 and Theorem 13.4.3 both move a structure from a point to an isomorphic point. The text does it in two ways: through $F|_{U(x_y)}$ for points in $F(X)$, and through $t \circ (s|_{U(\psi)})^{-1}$ for points reached by a morphism ψ. The formalization does both moves at once, by one chart along a morphism. This subsection sets the chart up, for a strong bundle equivalence Φ over $F : X \to X'$. Proposition 13.4.2 uses it for F the identity.

The chart at $y \in X'$ Chapter13/SymmetricStructurePush · SBLocalization.PushChart. - *Choices.* F is essentially surjective, so there are $x_y \in X$ and a morphism $\sigma_y : F(x_y) \to y$. - *The transport chart* (Chapter 10, Part X) is

$$Q = t \circ (s|_{\text{sheet of } \sigma_y})^{-1} \circ F$$

near x_y. It comes with morphisms $\psi_u : F(u) \to Q(u)$, ψ_u the morphism of the sheet through σ_y with source $F(u)$. Q is an sc-diffeomorphism from an open $W \ni x_y$ onto an open $W' \ni y$, with inverse Q^{-1}. - A chart is chosen at every y Chapter13/SymmetricStructurePush · SBLocalization.pushChart. - For $y = F(x)$ and σ_y the unit, Q is the text's $F|_{U(x_y)}$.

The isotropy isomorphism Chapter13/SymmetricStructurePush · SBLocalization.conjEquiv. $g \mapsto \psi \circ F(g) \circ \psi^{-1}$, $G_{x_y} \to G'_y$, with $\psi = \psi_{x_y}$, is a group isomorphism (Remark 10.1.12, Part X). It is bijective because F is an equivalence.

Push neighbourhoods Chapter13/SymmetricStructurePush · SBLocalization.IsPushNbhd. For a neighbourhood N of x_y with the natural action, a neighbourhood N' of y with the natural action is a push neighbourhood if: - $U' \subset W'$ and $Q^{-1}(U') \subset U$; - $Q^{-1}(U')$ is invariant under G_{x_y} within the chart; - the natural actions are intertwined (2021 (10.2)–(10.3)): for $u = Q^{-1}(z)$,

$$\Gamma'(\psi F(g)\psi^{-1}, z) = \psi_{g*u} \circ F(\Gamma(g,u)) \circ \psi_u^{-1}.$$

Consequences: - $(\psi F(g)\psi^{-1}) * z = Q(g * Q^{-1}(z))$ Chapter13/SymmetricStructurePush · SBLocalization.IsPushNbhd.Φ_eq, applying t. - The identity $\Gamma'(\cdot, z) \circ \psi_u = \psi_{g*u} \circ F(\Gamma(g,u))$ Chapter13/SymmetricStructurePush · SBLocalization.IsPushNbhd.Γ_comp_ψ.

Existence, with the properness property Chapter13/SymmetricStructurePush · SBLocalization.exists_isPushNbhd. 1. Inside $Q(W_0)$, with W_0 the invariant core of U in the chart domain, take a neighbourhood of y with the natural action and proper closure (§XIII.1). 2. The two lifts $z \mapsto \Gamma'(\psi F(g)\psi^{-1}, z)$ and $z \mapsto \psi_{g*u} \circ F(\Gamma(g,u)) \circ \psi_u^{-1}$ through s are continuous, have source z, and agree at y. So they agree on

an open set, as in §XIII.19. 3. Restrict to the invariant core of that open set.

Pushed sections Chapter13/SymmetricStructurePush · SBLocalization.pushSec: $z \mapsto \mu'(\psi_u, \Phi(s(u)))$ with $u = Q^{-1}(z)$, the transported section of §XIII.9 along $\psi \circ Q^{-1}$. For an sc⁺-section s on U it is an sc⁺-section on U' Chapter13/SymmetricStructurePush · SBLocalization.IsPushNbhd.isScPlusSectionOn_pushSec: - Q^{-1} is sc-smooth; - Φ is a strong bundle map; - $z \mapsto \psi_{Q^{-1}(z)}$ is sc-smooth, a composite of the sheet inverse with F.

The pushed symmetric structure Chapter13/SymmetricStructurePush · SBLocalization.pushStructure. A symmetric structure of Λ on N gives one of $\Phi_*\Lambda$ on N': - $I'_y = I_{x_y}$, with G'_y acting through the inverse of the isotropy isomorphism; - $s'_i =$ push s_i.

Equivariance is the intertwining identity together with $\Phi\mu = \mu'\Phi$ and the composition law of μ'. The count: push $s_i(z) = w'$ iff $s_i(u) = \Phi^{-1}(\mu'(\psi_u^{-1}, w'))$. $\Phi_*\Lambda$ at w' is Λ at that vector, Chapter 11's push-forward being defined through any preimage.

Lifting morphisms Chapter13/MultisectionPushforward · SBLocalization.PushChart.liftMor. For charts T at y and T' at y' and a morphism φ' from W' to $W'_{T'}$, the lift is the unique $\varphi : u \to u'$, $u = Q^{-1}(s\varphi')$, $u' = Q'^{-1}(t\varphi')$, with

$$\psi'_{u'} \circ F(\varphi) = \varphi' \circ \psi_u$$

Chapter13/MultisectionPushforward · SBLocalization.PushChart.comp_liftMor. - *Existence:* F is full, so the morphism $\psi'^{-1}_{u'} \circ \varphi' \circ \psi_u : F(u) \to F(u')$ is $F(\varphi)$ for some φ. - *Uniqueness:* F is faithful.

Properties of the lift: - *Continuous* Chapter13/MultisectionPushforward · SBLocalization.PushChart.continuousOn_liftMor. A map into the morphisms of X is continuous at a point when its source, target and F-image are Chapter13/MultisectionPushforward · SBLocalization.PushChart.continuousAt_of_mor. F on morphisms is a local sc-diffeomorphism, so near $f(a)$ a local inverse recovers f from $F \circ f$, provided f stays in the sheet. That is forced by faithfulness, and by the continuity of $s \circ f$ and $t \circ f$, which pin the sheet. For the lift, source and target are Q^{-1} and Q'^{-1} of continuous functions, and the F-image is $\psi' \circ \varphi' \circ \psi^{-1}$, continuous. - *Injective* Chapter13/MultisectionPushforward · SBLocalization.PushChart.injOn_liftMor: φ' is recovered as $\psi' \circ F(\varphi) \circ \psi^{-1}$. - *Functorial* Chapter13/MultisectionPushforward · SBLocalization.PushChart.liftMor_comp Chapter13/MultisectionPushforward · SBLocalization.PushChart.liftMor_inv: by uniqueness of lifts. - *Compatible with* Γ Chapter13/MultisectionPushforward · SBLocalization.PushChart.liftMor_Γ: the lift of $\Gamma'(\psi F(g)\psi^{-1}, z)$ is $\Gamma(g, Q^{-1}z)$, by the intertwining identity. - *Compatible with the bi-action* Chapter13/MultisectionPushforward · SBLocalization.PushChart.liftMor_biact: from functoriality and compatibility with Γ. - *Carries components to components* Chapter13/MultisectionPushforward · SBLocalization.PushChart.isDiffeoComponent_push. A component Σ' of $\mathcal{U}'(y, y')$ is mapped by the continuous lift into a component Σ of $\mathcal{U}(x_y, x_{y'})$, where s and t are injective. The lift is injective, and source and target of the lift determine those of φ' through Q, Q'. So condition (3) of good systems is carried forward. - *The pushed sections are compatible along the lift* Chapter13/MultisectionPushforward · SBLocalization.PushChart.pushSec_compat: $\mu'(\varphi', \text{push } s(s\varphi')) = \mu'(\psi'_{u'}, \Phi(\mu(\varphi, s(u))))$, by $\varphi' \circ \psi_u = \psi'_{u'} \circ F(\varphi)$ and $\Phi\mu = \mu'\Phi$.

XIII.21 Proposition 13.4.2 (2017: Proposition 13.6): extension from an open V with $|V| = |X|$

Structured data on V. The text takes the strong bundle $W|V$ over the open full sub-ep-groupoid V and a structured sc⁺-multisection functor on it. The project has no strong bundle over an open sub-ep-groupoid, so the data are read relative to V inside W. - *A functor on $W|V$* Chapter13/

StructuredExtensionData · SBLocalization.IsWFunctorOn is a $\Lambda : W \to \mathbb{Q}^+$ invariant along morphisms with both ends in V. Its values over $X \setminus V$ are irrelevant. Two vectors over V in one orbit have the same value Chapter13/StructuredExtensionData · SBLocalization.IsWFunctorOn.eq_of_π_eq, since the morphism joining them has both ends in V. - *An sc⁺-multisection on $W|V$* Chapter13/StructuredExtensionData · SBLocalization.IsScPlusMultisectionOn is such a functor with a local section structure around every $q \in V$ on the domain of a natural representation inside V. The natural representations of the ep-groupoid V are those of X with domain in V. - *Structured data on V* Chapter13/StructuredExtensionData · SBLocalization.StructuredOn are Definitions 13.3.4 and 13.3.6 with every index in V: - neighbourhoods $N(q)$, $q \in V$, with $U(q) \subset V$, good for V in the sense of Theorem 13.1.7 as printed (§XIII.5); - symmetric structures (I_q, s_i^q) representing Λ on $U(q)$; - correspondences $\tau_{q,q'}$ on $\mathcal{U}(q, q')$, locally constant with finitely many values, with the bi-action, the compatibility with the sections, the diagonal and the swap.

Each I_q is nonempty, by the argument of §XIII.9. - *Witness.* Every structured tuple on X gives structured data with $V = X$ Chapter13/StructuredExtensionData · SBLocalization.StructuredTuple.toStructuredOn, for instance the zero multisection's on a paracompact orbit space.

The extension functor Chapter13/StructuredExtensionData · SBLocalization.extendMult. $\bar{\Lambda}(w) = \Lambda(w_0)$ for some w_0 over V in the orbit of w in W. - Such w_0 exists because $\pi(V) = |X|$ Chapter13/StructuredExtensionData · SBLocalization.exists_mem_of_π_image. A morphism $\varphi : q \to P(w)$ with $q \in V$ gives $w_0 = \mu(\varphi^{-1}, w)$. - The value does not depend on the choice, by the previous paragraph, and depends only on the orbit of w Chapter13/StructuredExtensionData · SBLocalization.extendMult_congr. - It is a functor on W Chapter13/StructuredExtensionData · SBLocalization.isWFunctor_extendMult, because w and $\mu(\varphi, w)$ have the same orbit. - It equals Λ over V Chapter13/StructuredExtensionData · SBLocalization.extendMult_eq: for w over V, take $w_0 = w$. - Every functor on W that agrees with Λ over V is $\bar{\Lambda}$ Chapter13/StructuredExtensionData · SBLocalization.eq_extendMult, since every orbit meets V.

This uniqueness is how "canonical" is read.

Unit charts. At a point $q \in V$ the extension keeps the given data, through the *unit chart* of the identity equivalence Chapter13/StructuredExtensionData · SBLocalization.unitChart: $Q = \mathrm{id}$ and $\psi_u = 1_u$. - The identity is a strong bundle equivalence Chapter13/StructuredExtensionData · SBLocalization.equivalences_id_sep, and push-forward along it is the identity on functors Chapter13/StructuredExtensionData · SBLocalization.pushMult_id. - A neighbourhood is a push neighbourhood of itself for the unit chart Chapter13/StructuredExtensionData · SBLocalization.isPushNbhd_unit, because the isotropy isomorphism is the identity. - Pushed sections are the given sections Chapter13/StructuredExtensionData · SBLocalization.pushSec_unit and lifted morphisms are the given morphisms Chapter13/StructuredExtensionData · SBLocalization.liftMor_unit, since $\mu(1, w) = w$. - Push neighbourhoods pass to smaller neighbourhoods with the same action Chapter13/StructuredExtensionData · SBLocalization.IsPushNbhd.of_le.

Extension charts Chapter13/StructuredExtensionData · SBLocalization.ExtChart. At a point x, an extension chart consists of: - a point $q_x \in V$ and a morphism $\psi_x : q_x \to x$; - the transport chart of the identity along ψ_x, $Q = t \circ (s|_{\text{sheet of } \psi_x})^{-1}$, which is the text's D_x; - a push neighbourhood $U(x)$ of $U(q_x)$ with the properness property.

Charts are chosen as follows. - At $x \in V$ the unit chart is used Chapter13/StructuredExtensionData · SBLocalization.unitExt. - At $x \notin V$ a chart exists inside any open $O \ni x$ Chapter13/StructuredExtensionData · SBLocalization.exists_extChart: §XIII.20 with $F = \mathrm{id}$, then restriction to O. - A choice of all charts with these properties Chapter13/StructuredExtensionData · SBLocalization.ExtSetup Chapter13/StructuredExtensionData · SBLocalization.extChart gives unit charts on V Chapter13/

StructuredExtensionData · SBLocalization.extChart_of_mem.

The extended structure. 1. *At each x* Chapter13/StructuredExtension · SBLocalization.ExtChart.sym: the structure at q_x pushed along the chart, $I_x = I_{q_x}$. For the identity equivalence, $\Phi_*\bar\Lambda = \bar\Lambda$, and $\bar\Lambda = \Lambda$ over $U(q_x) \subset V$. So the pushed structure represents $\bar\Lambda$ on $U(x)$. Hence $\bar\Lambda$ is an sc⁺-multisection on W Chapter13/StructuredExtension · SBLocalization.isScPlusMultisection_extendMult: a symmetric structure gives a local section structure Chapter13/StructuredExtension · SBLocalization.hasLocalSectionStructure_of_symmetricOn. 2. *Correspondences* Chapter13/StructuredExtension · SBLocalization.ExtChart.tau: $\tau_{x,x'}(\varphi) = \tau_{q_x,q_{x'}}(\mathrm{lift}\,\varphi)$, with the lift of §XIII.20 through the two charts. - The text distinguishes three cases: both ends in V, one end, neither, with maps A and C and a pseudo-inverse. The lift covers them uniformly. For the identity, the lift is the text's C; it is A when $x \in V$ and its inverse when $x' \in V$. 3. *The good system* Chapter13/StructuredExtension · SBLocalization.extGood of the chart neighbourhoods. Condition (3) is carried from $(U(q))_{q\in V}$ by the lift Chapter13/StructuredExtension · SBLocalization.ExtChart.isDiffeoComponent, as in §XIII.20. 4. *The decoration, the structure and the tuple* Chapter13/StructuredExtension · SBLocalization.extDecoration Chapter13/StructuredExtension · SBLocalization.extTau Chapter13/StructuredExtension · SBLocalization.extTuple. The conditions of Definitions 13.3.4 and 13.3.6 for τ are those of the given $\tau_{q,q'}$, through the properties of the lift: continuity, functoriality, compatibility with Γ and the bi-action, and compatibility of pushed sections. 5. *The given data are kept at the points of V.* There the charts are unit charts, so: - the actions on the index sets are the given ones Chapter13/StructuredExtension · SBLocalization.extSym_smul_of_eq; - the sections are the given ones Chapter13/StructuredExtension · SBLocalization.extSym_s_of_eq; - the correspondences on $\mathcal{U}(q,q')$ are the given ones Chapter13/StructuredExtension · SBLocalization.extTau_of_eq.

All three hold through the identifications of the index types.

Proposition 13.4.2 (restated), pp. 623–625 Chapter13/StructuredExtension · SBLocalization.proposition_13_4_2. Let V be open with $\pi(V) = |X|$, and structured data on V for Λ be given. - (1) $\bar\Lambda$ is an sc⁺-multisection on W, equal to Λ over V, and the only functor on W with this property. - (2) For every family of open $O(x) \ni x$ there is a structured tuple for $\bar\Lambda$ with the following properties: - its neighbourhoods at $q \in V$ are the given $U(q)$, and $U(x) \subset O(x)$ for $x \notin V$; - its index sets with their G_q-actions, its sections on $U(q)$ and its correspondences on $\mathcal{U}(q,q')$ are the given ones at the points of V.

Structurable Chapter13/StructuredExtension · SBLocalization.proposition_13_4_2_structurable: $\bar\Lambda$ is structurable.

Restated: the structured data relative to V replace a structure on the bundle $W|V$. The good-system condition on V is that of Theorem 13.1.7 as printed for the open V. "Canonical" is uniqueness among functors. No hypothesis is added.

XIII.22 Theorem 13.4.3 (2017: Theorem 13.4): push-forward along a strong bundle equivalence, and generalized strong bundle isomorphisms

The pushed good system Chapter13/MultisectionPushforward · SBLocalization.pushGood. Let Φ be a strong bundle equivalence over $F : X \to X'$ and $(\Lambda, \mathcal{U}, S, \tau)$ a structured tuple. - At each $y \in X'$, take the chart of §XIII.20 and a push neighbourhood of $U(x_y)$ Chapter13/MultisectionPushforward · SBLocalization.pushNbhd Chapter13/MultisectionPushforward · SBLocalization.isPushNbhd_pushNbhd. - Properness holds by construction. - Condition (3) holds by the lift.

The pushed structure. - *Decoration* Chapter13/MultisectionPushforward · SBLocalization.pushDecoration:

the pushed symmetric structures of §XIII.20, $I'_y = I_{x_y}$. - *Correspondences* Chapter13/MultisectionPushforward · SBLocalization.pushTau: $\tau'_{y,y'}(\varphi') = \tau_{x_y,x_{y'}}(\mathrm{lift}\,\varphi')$. - Local constancy: τ is locally constant and the lift continuous. - Finiteness: values of τ. - Equivariance: compatibility of the lift with the bi-action, and the isotropy isomorphisms on index sets. - Diagonal: the lift of Γ' is Γ. - Swap: the lift of an inverse is the inverse of the lift. - Compatibility: the pushed sections are compatible along the lift, and the lift maps components into components. - *The tuple* Chapter13/MultisectionPushforward · SBLocalization.pushTuple.

Theorem 13.4.3 (same), pp. 625–626 Chapter13/MultisectionPushforward · SBLocalization.theorem_13_4_3 Chapter13/MultisectionPushforward · SBLocalization.theorem_13_4_3_structured. $\Phi_*\Lambda$, Chapter 11's push-forward, is structurable when Λ is. A structured tuple pushes to a structured tuple with $I'_y = I_{x_y}$ and the pushed sections and correspondences.

Where the formal proof departs from the text. The text structures $\Phi_*\Lambda$ on $F(X)$ through $F|_{U(x_y)}$, then extends by Proposition 13.4.2 from $F(X)$, which has $|F(X)| = |X'|$. The formal proof gives every y, in $F(X)$ or not, a chart along σ_y. This does both steps at once and does not use Proposition 13.4.2. No canonicity is claimed, as in the text. No hypothesis is added.

Generalized strong bundle isomorphisms. A diagram $W \xleftarrow{\Phi} V \xrightarrow{\Psi} W'$ of strong bundle equivalences gives push-forwards $[D]_* = \Psi_*\Phi^*$ and pull-backs $[D]^* = \Phi_*\Psi^*$ of functors (Chapter 11, Part XI). Composing Theorems 13.4.1 and 13.4.3: - both preserve structurability Chapter13/MultisectionPushforward · SBLocalization.SDiagram.isStructurable_pushMult Chapter13/MultisectionPushforward · SBLocalization.SDiagram.isStructurable_pullMult; - so do push-forwards and pull-backs along a generalized strong bundle isomorphism Chapter13/MultisectionPushforward · SBLocalization.GenSBMap.isStructurable_pushMult Chapter13/MultisectionPushforward · SBLocalization.GenSBMap.isStructurable_pullMult, through any representing diagram.

The text says this "follows immediately" at the opening of §16.5. The interior case of Proposition 14.1.8 uses it (Part XIV).

XIII.23 Theorem 13.4.4 (2017: Theorem 13.5): pull-back along a proper strong bundle covering

Theorem 13.4.4 (same), pp. 626–628 Chapter13/MultisectionPullback · SBLocalization.theorem_13_4_4 Chapter13/MultisectionPullback · SBLocalization.theorem_13_4_4_structured. For a proper strong bundle covering $\Phi : W \to W'$ over $F : X \to X'$, the 2021 Definition 8.5.9 (Part VIII): - $\Phi^*\Lambda'$ is structurable when Λ' is; - a structured Λ' gives a structured class on $\Phi^*\Lambda'$, with $I_y = I'_{F(y)}$, G_y acting through F, $\Phi(s_i^y(z)) = s_i'^{F(y)}(F(z))$, and $\tau_{y,y'}(\varphi) = \tau'_{F(y),F(y')}(F(\varphi))$; - the same canonicity as Theorem 13.4.1 holds.

Proof. The covering gives pull-back data (§XIII.19) Chapter13/StrongBundlePullMap · SBLocalization.PullMap.ofCovering. 1. Φ intertwines the actions and is a local strong bundle isomorphism: Definition 8.5.9. 2. F is faithful: by Definition 8.5.1 (3) the map $\varphi \mapsto (F(\varphi), s(\varphi))$ is an sc-diffeomorphism onto the fibred product, so two morphisms with the same source and the same image agree. 3. The rest is the construction of §XIII.19, word for word. - The text's identity $F(\Gamma_Y(g,z)) = \Gamma_X(F(g),F(z))$ is the third clause of an adapted neighbourhood. It is obtained by the same open-set argument. - The text's disjoint decomposition $F^{-1}(U(x)) = \bigsqcup V(z)$ is not needed: adapted neighbourhoods suffice, since only injectivity of

F on $U(y)$ and $F(U(y)) \subset U'(F(y))$ enter.

No hypothesis is added; paracompactness is not used.

XIII.24 Definition 13.4.5 (2017: Definition 13.22): commensurable structured sc⁺-multisections and their sums

A choice of common data `Chapter13/Commensurable · SBLocalization.CommData`. A choice c consists of: - a good system $\mathcal{U}$; - nonempty finite index types I_x with G_x-actions; - maps $\tau_{x,x'}$ from morphisms to $J(I_x, I_{x'})$ satisfying the conditions of Definitions 13.3.4 (1)–(2) and 13.3.6 (1)–(2), which do not involve sections.

The actions are determined by τ `Chapter13/Commensurable · SBLocalization.CommData.smul_eq_of_diag`. By Definition 13.3.6 (1) at $y = x$, $\tau_{x,x}(\Gamma(g,x)) = [\mathrm{id}, g]$, and $[\mathrm{id}, e] = [\mathrm{id}, e']$ only if $e = e'$ `Chapter13/Commensurable · SBLocalization.IndexCorr.ofEquiv_injective`: an equivalence c of the two diagrams satisfies $c = \mathrm{id}$, from the first leg, and then $e = e'$. So including the actions in c adds nothing to the text's "$\tau_1 = \tau_2$".

Sections over c `Chapter13/Commensurable · SBLocalization.CommData.Sections` are sections s_i^x, $i \in I_x$, on every $U(x)$ that are: - sc⁺; - equivariant; - compatible with τ in the sense of Definition 13.3.4 (3) `Chapter13/Commensurable · SBLocalization.CommData.Compat`.

No functor is given yet; the counting formula defines one: - $\mathrm{count}_x(w) = |I_x|^{-1}\#\{i : s_i^x(P(w)) = w\}$ `Chapter13/Commensurable · SBLocalization.CommData.countAt`; - the functor takes the count at $x = P(w)$ `Chapter13/Commensurable · SBLocalization.CommData.sumMult`.

Data over c for a given Λ `Chapter13/Commensurable · SBLocalization.CommData.Over` are sections over c with the counting formula for Λ on every $U(x)$. They give a structured tuple and a structured class `Chapter13/Commensurable · SBLocalization.CommData.Over.toStructured`. Every structured tuple T is of this form, over its own choice `Chapter13/Commensurable · SBLocalization.CommData.ofTuple Chapter13/Commensurable · SBLocalization.CommData.Over.ofTuple_toTuple`. The index sets are nonempty there because the index sets of every symmetric structure are (§XIII.9).

Count transport along a correspondence `Chapter13/Commensurable · SBLocalization.IndexCorr.count_eq_of_sat`. Let $I_x \xleftarrow{a} I \xrightarrow{b} I_{x'}$ represent τ, with $s'_{b(k)} = f(s_{a(k)})$ for all k and f injective on the relevant values. Then

$$|I_x|^{-1}\#\{i : s_i = v\} = |I_{x'}|^{-1}\#\{j : s'_j = f(v)\}.$$

1. If I_x is empty, so are I and $I_{x'}$, by surjectivity, and both sides are 0. 2. Let p be the common fibre size of a and q that of b, both positive. Then $|I| = p|I_x| = q|I_{x'}|$ `Chapter13/Commensurable · SBLocalization.IndexCorr.card_filter_comp_eq`, by counting I fibrewise. 3. Count the $k \in I$ with $s_{a(k)} = v$ in two ways. - Fibrewise over a: $p\#\{i : s_i = v\}$. - The condition is equivalent to $s'_{b(k)} = f(v)$, by the relation and injectivity of f. Fibrewise over b: $q\#\{j : s'_j = f(v)\}$. 4. Divide by the equal numbers $p|I_x| = q|I_{x'}|$.

This is why the counting formula of (2) defines a functor and does not depend on x: - *Along a morphism* `Chapter13/Commensurable · SBLocalization.CommData.Sections.countAt_fibAct`: for $\varphi \in \mathcal{U}(x,x')$, $\mathrm{count}_x(v) = \mathrm{count}_{x'}(\mu(\varphi, v))$. Use compatibility at φ itself and injectivity of $\mu(\varphi,\cdot)$. - *Independent of x* `Chapter13/Commensurable · SBLocalization.CommData.Sections.countAt_eq`: $\mathrm{count}_x(w) = \mathrm{count}_{P(w)}(w)$ for $P(w) \in U(x)$. Apply the previous item to the unit $1_{P(w)} \in \mathcal{U}(x, P(w))$. - *A functor* `Chapter13/Commensurable · SBLocalization.CommData.Sections.isWFunctor_sumMult`: apply the first item to $\varphi \in \mathcal{U}(s\varphi, t\varphi)$. -

An sc⁺-multisection `Chapter13/Commensurable · SBLocalization.CommData.Sections.isScPlusMultisection_sumMult`: on each $U(x)$ the sections s_i^x with weights $|I_x|^{-1}$ are a local structure, by independence of x.

Definition 13.4.5 (1) (restated), p. 628 `Chapter13/Commensurable · SBLocalization.Commensurable`. Two structured classes are commensurable if they have representatives over one common c. The relation is reflexive `Chapter13/Commensurable · SBLocalization.Commensurable.refl`, by the choice of the tuple itself, and symmetric `Chapter13/Commensurable · SBLocalization.Commensurable.symm`. The paracompactness of $|X|$ in the text's setting is not needed for the definition. *Restated*: "representatives can be taken with $\mathcal{U}_1 = \mathcal{U}_2$, $\tau_1 = \tau_2$, $I_x^1 = I_x^{2}$" is "data over one c".

The locally finite commensurable sum (same), p. 629 `Chapter13/Commensurable · SBLocalization.CommData.definition_13_4_5_lf`. Let $(\Lambda_j)_{j\in J}$ be locally finite (Definition 13.2.12) with data over one c. Then: - the sections $s_i^x = \sum_j s_i^{j,x}$ are defined; - they are sections over c; - $\bigoplus_j^c \Lambda_j$, their count, is an sc⁺-multisection with these data, and $\Lambda(w) = |I_x|^{-1}\#\{i : s_i^x(P(w)) = w\}$ for $P(w) \in U(x)$.

Proof. 1. *Finitely many nonzero summands near each point* `Chapter13/Commensurable · SBLocalization.CommData.exists_finite_support`. Over $O(y)$ of Definition 13.2.12, every j outside the finite set has Λ_j trivial, and its sections vanish there (§XIII.9). 2. So near each point $\sum_j s_i^{j,x}$ is a finite sum of sections extended by zero `Chapter13/Commensurable · SBLocalization.CommData.sumSec_eq_sectionSum`. Being sc⁺ on an open set is local `Chapter13/Commensurable · SBLocalization.IsScPlusSectionOn.of_locally`, so the sum is sc⁺. 3. Equivariance and compatibility are additivity of $\mu(\psi, \cdot)$ over finitely supported sums `Chapter13/Commensurable · SBLocalization.fibAct_finsum`. Compatibility of the sum needs one representative that works for all j at once: the conjunction of the relations is saturated when each is `Chapter13/Commensurable · SBLocalization.IndexCorr.sat_iInter`, since all j share the same τ. 4. The sections over c are `Chapter13/Commensurable · SBLocalization.CommData.lfSections`, and the count is an sc⁺-multisection by the previous paragraph.

"Pairwise commensurable" is read as "over one common c", which is what the text's notation $[\Lambda_j, \mathcal{U}, S_j, \tau]$ writes. "Locally finite" is Definition 13.2.12; the text's condition after Definition 13.4.5 is the same with "open". The text calls the construction evident; its well-definedness is the count transport above.

Definition 13.4.5 (2) (same), p. 628 `Chapter13/Commensurable · SBLocalization.CommData.definition_13_4_5`. Over a common c, the sum $\Lambda_1 \oplus_c \Lambda_2$ has sections $s_i^x = s_i^{1,x} + s_i^{2,x}$, and $\Lambda(w) = |I_x|^{-1}\#\{i : s_i^x(P(w)) = w\}$ on $U(x)$. It is an sc⁺-multisection with these data. It is the locally finite sum over a two-element index set `Chapter13/Commensurable · SBLocalization.CommData.commSum₂`. A finite family is locally finite, with $O(x) = X$.

The index set of $\Lambda_1 \oplus_c \Lambda_2$ is I_x, not $I_x^1 \times I_x^2$. The commensurable sum is a different operation from the sum of §XIII.11. In general the two functors differ, since the commensurable sum adds sections with the same index only.

XIII.25 Definition 13.5.1 (2017: Definition 13.23) and Remark 13.5.2 (2017: Remark 13.6): atomic sc⁺-multisections

Atomic data `Chapter13/AtomicMultisection · SBLocalization.AtomicData` are the data of Definition 13.5.1 (1)–(2), p. 629: - a point x; - a natural representation of G_x on $U(x)$, with the properness property: $t : s^{-1}(\mathrm{cl}\, U(x)) \to X$ is proper; - an open $V \ni x$, invariant under every $\Phi(g)$, with $\mathrm{cl}\, V \subset U(x)$; - a finite index type I with a G_x-action; - sc⁺-sections s_i on $U(x)$ that are equivariant, $s_{g(i)}(g{*}y) = \mu(\Gamma(g,y), s_i(y))$ for $y \in U(x)$, and vanish on $U(x) \setminus V$.

The text's "G_x-invariant open neighbourhood $U(x)$" is read here as the domain of a natural representation (Theorem 7.1.13, Part VII). A second reading, on neighbourhoods with the natural action, follows below. Both readings are used.

The count, and condition (3). - *The count* `Chapter13/AtomicMultisection · SBLocalization.AtomicData.count` of a vector w' is $|I|^{-1}\#\{i : s_i(P(w')) = w'\}$. - *Reachable points* `Chapter13/AtomicMultisection · SBLocalization.AtomicData.Reach`: y is reachable if some morphism φ has $s(\varphi) = y$ and $t(\varphi) \in U(x)$. The reachable points are the saturation of $U(x)$ `Chapter13/AtomicMultisection · SBLocalization.AtomicData.reach_iff_mem_saturation`. - *Condition (3)* `Chapter13/AtomicMultisection · SBLocalization.AtomicData.IsRelated`. A functor Λ is related to the data if two things hold: - $\Lambda(w)$ is the count of $\mu(\varphi, w)$ for every morphism φ from $P(w)$ into $U(x)$; - Λ agrees with the zero multisection over the points that are not reachable. - *Atomic* (restated), p. 629 `Chapter13/AtomicMultisection · SBLocalization.IsAtomic`: an sc⁺-multisection related to some atomic data.

The count does not depend on the morphism. The text writes condition (3) for any φ with $t(\varphi) \in U(x)$, and does not say that the value is independent of the choice. It is. 1. *Equivariance permutes the indices* `Chapter13/AtomicMultisection · SBLocalization.AtomicData.card_filter_μ_Γ`. For $g \in G_x$ and $y \in U(x)$, the permutation $i \mapsto g(i)$ is a bijection from $\{i : s_i(y) = w\}$ to $\{i : s_i(g * y) = \mu(\Gamma(g, y), w)\}$. This is the equivariance of the sections, together with injectivity of $\mu(\Gamma(g, y), \cdot)$ on the fibre. 2. *So the count is invariant under the* $\Gamma(g, \cdot)$ `Chapter13/AtomicMultisection · SBLocalization.AtomicData.count_μ_Γ`. 3. *Two morphisms from* $P(w)$ *into* $U(x)$ *give the same count* `Chapter13/AtomicMultisection · SBLocalization.AtomicData.count_μ_eq`. - For φ, φ' from $P(w)$ into $U(x)$, the morphism $\psi = \varphi' \circ \varphi^{-1}$ joins two points of $U(x)$. So it is $\Gamma(g, t\varphi)$ for some $g \in G_x$: the natural representation is onto the morphisms between points of $U(x)$. - Then $\mu(\varphi', w) = \mu(\psi, \mu(\varphi, w))$, and step 2 applies.

The multisection of the data `Chapter13/AtomicMultisection · SBLocalization.AtomicData.mult`. It is the count of $\mu(\varphi, w)$ for some φ from $P(w)$ into $U(x)$ when $P(w)$ is reachable, and the zero multisection otherwise. - It is computed by any such φ `Chapter13/AtomicMultisection · SBLocalization.AtomicData.mult_eq`, by the previous paragraph. - Off the reachable points it is trivial `Chapter13/AtomicMultisection · SBLocalization.AtomicData.mult_of_not_reach`. - Over $U(x)$ it is the count itself `Chapter13/AtomicMultisection · SBLocalization.AtomicData.mult_of_mem`, by the unit morphism. - It is related to the data `Chapter13/AtomicMultisection · SBLocalization.AtomicData.isRelated_mult`. - *Every functor related to the data is this one* `Chapter13/AtomicMultisection · SBLocalization.AtomicData.IsRelated.eq_mult`. So an atomic Λ is determined by its data. - *It is a functor* `Chapter13/AtomicMultisection · SBLocalization.AtomicData.isWFunctor_mult`. For a morphism ψ and w over $s(\psi)$: if $s(\psi)$ is reachable through φ, then $t(\psi)$ is reachable through $\varphi \circ \psi^{-1}$, and the two counts are those of the same vector. If not, neither is reachable, and the zero multisection is a functor.

Condition (2) as printed `Chapter13/AtomicMultisection · SBLocalization.AtomicData.IsRelated.symmetricStructure`. For a Λ related to the data, the data are a symmetric structure of Λ on $U(x)$ in the sense of Definition 13.2.5 (§XIII.9). The representation on $U(x)$ is the count. So the reading of (2) as "sections with a G_x-action and equivariance" agrees with the text's "symmetric sc⁺-section structure".

The index set is nonempty `Chapter13/AtomicMultisection · SBLocalization.AtomicData.IsRelated.nonempty`. For Λ an sc⁺-multisection related to the data, $I \neq \emptyset$. - The weights of Λ over x sum to 1, so some vector over x has positive weight. - With $I = \emptyset$ the count of every vector is 0.

The text does not say this. It matters for Theorem 13.5.5 (§XIII.28).

The local structure of the multisection of the data. 1. *Properness passes to* $\mathrm{cl}\, V$ `Chapter13/`

AtomicMultisection · SBLocalization.AtomicData.isProperSubset_closure_V: a closed subset of the proper $\mathrm{cl}\,U(x)$. 2. *The saturation of* $\mathrm{cl}\,V$ *is closed* Chapter13/AtomicMultisection · SBLocalization.AtomicData.isClosed_saturation_closure_V. This is the closedness of saturations of proper sets (Part VII). It lies in the saturation of $U(x)$ Chapter13/AtomicMultisection · SBLocalization.AtomicData.saturation_closure_V_subset. 3. *Off the saturation of* $\mathrm{cl}\,V$ *the multisection is trivial* Chapter13/AtomicMultisection · SBLocalization.AtomicData.mult_eq_zeroMultisection. At a reachable point outside it, the transported point $t(\varphi)$ lies in $U(x) \setminus V$, where all sections vanish. The count at a point where all sections vanish is the zero multisection Chapter13/AtomicMultisection · SBLocalization.AtomicData.count_eq_zeroMultisection: it is 1 at 0 and 0 elsewhere. 4. *So the domain support lies in the saturation of* $\mathrm{cl}\,V$ Chapter13/AtomicMultisection · SBLocalization.AtomicData.domSupp_mult_subset, which is closed. 5. *Near a reachable point* y_0 Chapter13/AtomicMultisection · SBLocalization.AtomicData.exists_isLocalRepOn_transport. - Choose φ_0 from y_0 into $U(x)$. The target map is a local sc-diffeomorphism at φ_0^{-1}, so there are an open $V_2 \ni y_0$ and an sc-smooth $\tau : V_2 \to \mathbf{X}$ with $t(\tau(z)) = z$ and $\tau(y_0) = \varphi_0^{-1}$. - On $O = V_2 \cap (s \circ \tau)^{-1}(U(x))$, which is open and contains y_0, the sections $s_i'(z) = \mu(\tau(z), s_i(s(\tau(z))))$ are sc$^+$, being transported sections in the sense of §XIII.9. - With weights $|I|^{-1}$ they represent the multisection. At w over $z \in O$, use the morphism $\tau(z)^{-1}$ from z into $U(x)$ in the count. 6. *Local section structures.* A local section structure at every reachable point Chapter13/AtomicMultisection · SBLocalization.AtomicData.hasLocalSectionStructure_of_reach. At every point outside the saturation of $\mathrm{cl}\,V$, the single zero section on the complement Chapter13/AtomicMultisection · SBLocalization.AtomicData.hasLocalSectionStructure_of_not_mem. These two cases cover all points. 7. *Conclusion.* The multisection of the data is an sc$^+$-multisection when $I \neq \emptyset$ Chapter13/AtomicMultisection · SBLocalization.AtomicData.isScPlusMultisection_mult, and it is atomic Chapter13/AtomicMultisection · SBLocalization.AtomicData.isAtomic_mult.

Witnesses. - *Atomic neighbourhoods exist inside every open set* Chapter13/AtomicMultisection · SBLocalization.exists_atomicNbhd. For x in an open W there are a natural representation on $U(x) \subset W$ with the properness property and an invariant open $V \ni x$ with $\mathrm{cl}\,V \subset U(x)$. This uses Theorem 7.1.13 and the shrinking in the proof of Theorem 7.5.7 (Part VII). - *The zero section at any point* Chapter13/AtomicMultisection · SBLocalization.AtomicData.zero. One index, the zero section, on such a neighbourhood. Its multisection is the zero multisection Chapter13/AtomicMultisection · SBLocalization.AtomicData.zero_mult. - So *the zero multisection is atomic*, at every point Chapter13/AtomicMultisection · SBLocalization.isAtomic_zeroMultisection.

Atomic on a neighbourhood with the natural action (extra) Chapter13/AtomicSum · SBLocalization.AtomicDataOn Chapter13/AtomicSum · SBLocalization.IsAtomicOn. This is Definition 13.5.1 with $U(x)$ a neighbourhood with the natural action (§XIII.1) and proper closure, in place of the domain of a natural representation. - The sets of a good system are of this kind, and they need not be connected. Theorem 13.5.7 produces atomic pieces on such sets, so it needs this reading (§XIII.30). - The count Chapter13/AtomicSum · SBLocalization.AtomicDataOn.count, reachability Chapter13/AtomicSum · SBLocalization.AtomicDataOn.Reach and condition (3) Chapter13/AtomicSum · SBLocalization.AtomicDataOn.IsRelated are as above. - Atomic data on the domain of a natural representation are atomic data in this sense Chapter13/AtomicSum · SBLocalization.AtomicData.toOn: the domain with the representation is a neighbourhood with the natural action. So atomic implies atomic in this sense Chapter13/AtomicSum · SBLocalization.IsAtomic.isAtomicOn, and the zero multisection is a witness.

Restated: $U(x)$ is the domain of a natural representation, and V is invariant under the $\Phi(g)$. The count is shown to be independent of φ. Condition (2) is the data of a symmetric structure.

Remark 13.5.2 (p. 630) is prose. It says that atomic multisections are built from one section moved around

by G_x, and that bump functions suffice, not partitions of unity. Theorems 13.5.4–13.5.6 below use bump functions only, as the remark says. Theorem 13.5.7 uses partitions of unity.

XIII.26 Theorem 13.5.3 (2017: Theorem 13.6): atomic sc⁺-multisections are structurable

The text constructs a structure for an atomic Λ in four cases: - points of $U(x_0)$, with index set I_{x_0}; - points near which Λ is trivial, with $\{*\}$; - the remaining points, through a morphism φ_x into $\operatorname{cl} V(x_0)$; - and correspondences between all pairs.

It closes with "one easily verifies" that the sections are compatible. The formalization reorganizes the cases around one closed saturated set Z and one function H, and verifies all compatibilities from two properties of H.

General tools. - *The full correspondence* `Chapter13/AtomicStructurable · SBLocalization.IndexCorr.full`. $[I \leftarrow I \times I' \to I']$ for nonempty finite I, I', built on the diagram `Chapter13/AtomicStructurable · SBLocalization.IndexDiagram.full`. - Its fibres have the sizes $|I'|$ and $|I|$ `Chapter13/AtomicStructurable · SBLocalization.IndexDiagram.card_fst_fiber` `Chapter13/AtomicStructurable · SBLocalization.IndexDiagram.card_snd_fiber`. - It is fixed by $\sharp$ up to the order of factors `Chapter13/AtomicStructurable · SBLocalization.IndexCorr.swap_full`, and by the bi-action `Chapter13/AtomicStructurable · SBLocalization.IndexCorr.biact_full`. - *Correspondences of bijections.* - The bi-action on $[\mathrm{id}, e]$ is $[\mathrm{id}, g'eg^{-1}]$ `Chapter13/AtomicStructurable · SBLocalization.IndexCorr.biact_ofEquiv`. - $\sharp$ of $[\mathrm{id}, e]$ is $[\mathrm{id}, e^{-1}]$ `Chapter13/AtomicStructurable · SBLocalization.IndexCorr.swap_ofEquiv`. - $[\mathrm{id}, e]$ saturates a relation R iff $R(i, e(i))$ for all i `Chapter13/AtomicStructurable · SBLocalization.IndexCorr.sat_ofEquiv`. - *Locally constant choices* `Chapter13/AtomicStructurable · SBLocalization.eventually_eq_of_existsUnique`. Let f and g_h, for h in a finite set, be continuous maps into a Hausdorff space on an open set, and suppose $f(z) = g_h(z)$ for exactly one h at every z. Then the h with $f(z_0) = g_h(z_0)$ still works near z_0. For each of the finitely many other h', $g_{h'}(z_0) \neq f(z_0)$, and this persists near z_0 by Hausdorffness and continuity. The equality for h itself is then forced by existence. - *Locally constant functions are constant on components* `Chapter13/AtomicStructurable · SBLocalization.eq_of_mem_connectedComponentIn`. The level sets are open in the open set, so each component lies in one of them. - *Composition rules for μ*, in the total form of §XIII.9: composition `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.fibAct_comp`, units `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.fibAct_unit`, and inverses `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.fibAct_inv_fibAct` `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.fibAct_fibAct_inv`. - The transported section of §XIII.9 is the action at each point `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.transportSection_eq_fibAct`. - $\varphi \circ (\varphi^{-1} \circ \chi) = \chi$ `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.comp_inv_comp`.

The data of the proof `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData`. - Atomic data D related to Λ, at x_0, with $I \neq \emptyset$. - A good system $\mathcal{U}_0$. - For every y in $Z = \pi^{-1}\pi(\operatorname{cl} V(x_0))$: an open $O(y) \ni y$ and an sc-smooth $\tau_y : O(y) \to \mathbf{X}$ with $t(\tau_y(z)) = z$ and $s(\tau_y(z)) \in U(x_0)$, along which the atomic sections transport to sc⁺-sections.

Existence `Chapter13/AtomicStructurable · SBLocalization.exists_atomicStructData`: for every atomic Λ with data D and every good system. A point of Z is reachable, and the local structure of §XIII.25 (step 5) gives $O(y)$ and τ_y. τ_y is the text's $(s|_{U(\varphi_x)})^{-1}$, inverted.

The set Z. Z `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.Z` is the saturation of $\operatorname{cl} V(x_0)$. - It is closed `Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.isClosed_Z`, by §XIII.25. - It is sat-

urated: the source of a morphism is in Z iff its target is Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.mem_Z_iff_of_mor. - Off Z, Λ is trivial (§XIII.25).

The text's four cases become two: $y \in Z$ and $y \notin Z$. The text's points of $U(x_0)$ outside Z, and its points with a neighbourhood where Λ is trivial, fall into the second case. Its points of $U(x_0)$ in Z use τ_y like every other point of Z, with no special treatment.

The partner function H. Fix $y, y' \in Z$. Write: - $\sigma_y(z) = s(\tau_y(z)) \in U(x_0)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.σ; - $\mathrm{Dom}(y, y')$ for the morphisms from $O(y)$ to $O(y')$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.Dom, an open set.

For $\psi \in \mathrm{Dom}(y, y')$ the conjugate

$$\mathrm{conj}(\psi) = \tau_{y'}(t\psi)^{-1} \circ \psi \circ \tau_y(s\psi)$$

Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.conj runs from $\sigma_y(s\psi)$ to $\sigma_{y'}(t\psi)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.src_conj Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.tgt_conj. These are two points of $U(x_0)$, so: 1. $\mathrm{conj}(\psi) = \Gamma(h, \sigma_y(s\psi))$ *for a unique* $h \in G_{x_0}$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.existsUnique_rel. Existence is the surjectivity of the natural representation. Uniqueness is its injectivity: $\Gamma(\cdot, z)$ is injective for each z. 2. $H(\psi)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H is this h, and 1 when $y \notin Z$, $y' \notin Z$ or $\psi \notin \mathrm{Dom}(y, y')$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_far. It is characterized by its defining equation Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_spec, and any h satisfying it is $H(\psi)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_eq_of_rel. 3. *Functorial* Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_comp Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_unit Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_inv: - $H(\psi_1 \circ \psi_2) = H(\psi_1)H(\psi_2)$, because the conjugates compose, the inner τ's cancelling, and $\Gamma(h_1, \cdot) \circ \Gamma(h_2, \cdot) = \Gamma(h_1 h_2, \cdot)$; - $H(1_z) = 1$; - $H(\psi^{-1}) = H(\psi)^{-1}$.

Each follows by uniqueness in step 1. 4. *Locally constant* Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_eventually. The conjugate depends continuously on ψ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.continuousOn_conj, since τ_y, $\tau_{y'}$, composition and inversion are continuous. Each $\psi \mapsto \Gamma(h, \sigma_y(s\psi))$ is continuous. G_{x_0} is finite, and the space of morphisms is Hausdorff. Apply the tool on locally constant choices.

The homomorphisms γ_y. For $y \in Z$, the morphism $\Gamma_0(g, y)$ of the natural representation of $\mathcal{U}_0$ at y lies in $\mathrm{Dom}(y, y)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.Γ₀_mem_Dom. Define

$$\gamma_y(g) = H(\Gamma_0(g, y))$$

Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.γ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.γ_apply. - It is a homomorphism $G_y \to G_{x_0}$: units by $H(1) = 1$, products by functoriality. - It is trivial for $y \notin Z$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.γ_far. - It is the text's γ_x in both of the text's cases. For $y \in U(x_0)$ it is defined by $\Gamma^y(g, y) = \Gamma^{x_0}(\gamma_y(g), y)$ when τ_y is the unit. For the other points of Z it is the conjugation $\varphi_x \circ g \circ \varphi_x^{-1}$.

The good system. The neighbourhoods must be small enough that H is constant along the natural action. 1. $W_n(y)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.Wn: the points z of $U_0(y) \cap O(y)$ with $g * z \in O(y)$ and $H(\Gamma_0(g, z)) = \gamma_y(g)$ for all g. 2. *It is a neighbourhood of y* Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.eventually_Wn. For each of the finitely many

g, local constancy of H at $\Gamma_0(g,y)$, with continuity of $z \mapsto \Gamma_0(g,z)$, gives a neighbourhood. Intersect them. 3. $W(y)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.W is the interior of $W_n(y)$ for $y \in Z$, and Z^c for $y \notin Z$. It is open Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.isOpen_W and contains y Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.mem_W. 4. $M(y)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.M is the invariant core of $U_0(y)$ in $W(y)$ (§XIII.1). It has the action of $\mathcal{U}_0$ at y. 5. *The good system* Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.□ is $(M(y))$, by the lemma of §XIII.10. Its properties: - $U(y) \subset W(y)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.U_subset_W; - $U(y) \subset W_n(y)$ for $y \in Z$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.mem_Wn, hence $U(y) \subset O(y)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.U_subset_0; - $U(y) \cap Z = \emptyset$ for $y \notin Z$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.not_mem_Z; - $H(\Gamma(g,z)) = \gamma_y(g)$ for $z \in U(y)$, $y \in Z$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.W_cond; - morphisms between $U(y)$ and $U(y')$ lie in $\mathrm{Dom}(y,y')$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.mor_subset_Dom.

The sections Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.sec. The index set is $I = I_{x_0}$ at every point. - For $y \in Z$, the transported sections $z \mapsto \mu(\tau_y(z), s_i(\sigma_y(z)))$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.sec_of_mem Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.sec_apply. They lie over the right points Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.P_s_σ. - For $y \notin Z$, the zero sections Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.sec_of_not_mem. - *Compatibility through H* Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.sec_compat. For $y, y' \in Z$ and $\psi \in \mathrm{Dom}(y,y')$:

$$\mathrm{sec}_{y'}(H(\psi)\cdot i)(t\psi) = \mu(\psi, \mathrm{sec}_y(i)(s\psi)).$$

Proof: 1. Write $\psi = \tau_{y'}(t\psi) \circ \Gamma(H(\psi), \sigma_y(s\psi)) \circ \tau_y(s\psi)^{-1}$. 2. Apply the composition rule for μ. 3. Apply the equivariance of the atomic sections at $\sigma_y(s\psi)$. - *Vanishing off Z* Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.sec_eq_zero. At a point $z \notin Z$ every section is zero. For $y \in Z$, $\sigma_y(z) \in U(x_0)$ lies outside $V(x_0)$, since $z \notin Z$, so the atomic sections vanish there.

The symmetric structures Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.S have index set I, with G_y acting through γ_y, and the sections above. - *Sc⁺:* transported sections are sc⁺ by the data. Zero sections are sc⁺. - *Equivariance:* for $y \in Z$, compatibility at $\Gamma(g,z)$ with $H(\Gamma(g,z)) = \gamma_y(g)$, which is the role of W_n. For $y \notin Z$, the zero sections are equivariant for any action. - *Representation by the count* (Definition 13.2.5): - for $y \in Z$, the count of Λ at w over $z \in U(y)$ is that of $\mu(\tau_y(z)^{-1}, w)$ over $\sigma_y(z) \in U(x_0)$, by Definition 13.5.1 (3), and $\mu(\tau_y(z), \cdot)$ carries the one count to the other; - for $y \notin Z$, Λ is trivial on $U(y)$ and the zero sections represent it, whatever $|I| \geq 1$ is.

The decoration is $(\mathcal{U}, S)$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.dec.

The correspondences Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.corr. For φ from $U(y)$ to $U(y')$:

$$\tau_{y,y'}(\varphi) = \begin{cases} [I \xleftarrow{\mathrm{id}} I \xrightarrow{H(\varphi)} I] & \text{if } y \in Z \Leftrightarrow y' \in Z, \\ [I \leftarrow I \times I \rightarrow I] & \text{otherwise} \end{cases}$$

Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.corr_of_iff Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.corr_of_not_iff.

When exactly one of y, y' lies in Z, the morphisms between $U(y)$ and $U(y')$ join points outside Z. One of the two sets misses Z, and Z is saturated. There all sections vanish, and the full correspondence is

compatible.

Definition 13.3.4 Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.isCorrespondence. 1. *Locally constant.* H is locally constant on the morphisms between $U(y)$ and $U(y')$ Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_eventually'. The full correspondence is constant. 2. *Finitely many values.* G_{x_0} is finite. 3. *Equivariance* Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.H_biact. $H(g' * \varphi * g) = \gamma_{y'}(g')H(\varphi)\gamma_y(g)^{-1}$, by functoriality and the condition of W_n. With the law for the bi-action on $[\mathrm{id}, e]$ this is Definition 13.3.4 (2). The full correspondence is fixed by the bi-action. 4. *Compatibility.* On a component Σ of $\mathcal{U}(y, y')$, H is constant, since it is locally constant. So for $\varphi \in \Sigma$ the relation saturated by $[\mathrm{id}, H(\varphi)]$ holds at every $\psi \in \Sigma$, by the compatibility of the sections through $H(\psi) = H(\varphi)$. Across Z and Z^c, all sections vanish.

Definition 13.3.6 Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.tau. - *Diagonal:* $\tau_{y,y}(\Gamma(g, z)) = [\mathrm{id}, H(\Gamma(g, z))] = [\mathrm{id}, \gamma_y(g)]$, by the condition of W_n. This is $[\mathrm{id}, g]$ for the action through γ_y. - *Swap:* $[\mathrm{id}, H(\varphi^{-1})] = [\mathrm{id}, H(\varphi)^{-1}] = [\mathrm{id}, H(\varphi)]^\sharp$, and the full correspondence is its own swap up to the order of factors.

So Λ is structurable Chapter13/AtomicStructurable · SBLocalization.AtomicStructData.isStructurable.

Where the formal proof departs from the text. The text uses $\{*\}$ with the zero section where Λ is trivial, and correspondences $[\{*\} \leftarrow I \rightarrow I]$ to such points. The formalization uses I with zero sections and the full correspondence. Both are structures in the sense of Definition 13.3.6. This is a different witness, not a different statement.

Theorem 13.5.3 (narrower), p. 630 Chapter13/AtomicStructurable · SBLocalization.theorem_13_5_3_of_goodSystem. If X has a good system, every atomic sc⁺-multisection is structurable.

The added hypothesis, that a good system exists, is not derived from the text, whose statement assumes nothing on X. It is necessary: for atomic Λ, structurable is equivalent to the existence of a good system Chapter13/AtomicStructurable · SBLocalization.theorem_13_5_3, since Definition 13.3.6 includes one. Its witness is Theorem 13.1.8 for paracompact $|X|$ (§XIII.6) Chapter13/GoodSystemExistence · EpGroupoid.theorem_13_1_8, which gives the form Chapter13/AtomicStructurable · SBLocalization.theorem_13_5_3_of_paracompact.

As printed, the theorem puts no hypothesis on X, but a structurable sc⁺-multisection contains a good system by Definition 13.3.6, so the statement needs one; Chapter 13 has no standing assumption that supplies it, and the formal statement names it (narrower, with the added hypothesis shown necessary). The text's proof begins by choosing neighbourhoods with the natural action and the properness property at every point, which is a good system in all but condition (3).

The local alternative, and a parametric form. A first Lean form of the theorem isolates the local part of the proof. - *The local alternative* Chapter13/AtomicStructurableLocal · SBLocalization.AtomicData.IsLocallyTransported Chapter13/AtomicStructurableLocal · SBLocalization.theorem_13_5_3_local. For atomic data of Λ, at every point y one of two things holds: - on an open $O \ni y$, Λ is represented by the atomic sections transported along an sc-smooth τ into $U(x_0)$, with weights $|I|^{-1}$; - Λ is trivial on an open $O \ni y$.

This is §XIII.25 (steps 3 and 5), split by reachability. - *Remark on the parametric form.* The same file states Theorem 13.5.3 for any predicate "structurable" that holds for every sc⁺-multisection with atomic data whose local alternatives hold everywhere Chapter13/AtomicStructurableLocal · SBLocalization.theorem_13_5_3_hyp. That hypothesis is satisfiable, with "structurable" read as "is an sc⁺-multisection" Chapter13/AtomicStructurableLocal · SBLocalization.theorem_13_5_3_hyp_witness. The last clause of Theorem 13.5.5 is stated in the same form Chapter13/AtomicStructurableLocal · SBLocalization.theorem_13_5_5_structurable_hyp.

The proof above supersedes the hypothesis for the predicate of Definition 13.3.6. The parametric clause is still the route by which the last clause of Theorem 13.5.5 is derived (§XIII.28), with Theorem 13.5.3 substituted for the parameter.

XIII.27 Theorem 13.5.4 (2017: Theorem 13.7): Construction I

Symmetric families `Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily`. These are the input of Theorem 13.5.5 (p. 633): for a natural representation of G_x on $U(x)$, - a finite index type I with a G_x-action; - sc⁺-sections s_i of $W \to X$, global, viewing X as an M-polyfold, with support in $U(x)$; - equivariance $s_{g(i)}(g * z) = \mu(\Gamma(g, z), s_i(z))$ for $z \in U(x)$.

Construction I produces such families. They vanish off V, which is stronger than "on $U(x) \setminus V$", since they are global and supported in V.

Auxiliary facts on μ and the auxiliary norm. - $\mu(\varphi, \cdot)$ preserves the level-1 part of the fibres `Chapter13/AtomicConstruction · SBLocalization.mem_oneSet_μ` `Chapter13/AtomicConstruction · SBLocalization.mem_oneSet_of_μ`, in both directions, since it is a strong bundle isomorphism of fibres. - An auxiliary norm N (Definition 8.3.5, 2021 numbering; Part VIII) is invariant: $N(\mu(\varphi, w)) = N(w)$ `Chapter13/AtomicConstruction · SBLocalization.normW_μ`. This is the compatibility of auxiliary norms with the structure maps. - The zero vector is at level 1 `Chapter13/AtomicConstruction · SBLocalization.fiberZero_mem_oneSet` and has norm 0 `Chapter13/AtomicConstruction · SBLocalization.normW_fiberZero`.

The family of one seed `Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.ofSeed`. Let s_0 be an sc⁺-section supported in an invariant open V with $\mathrm{cl}\, V \subset U(x)$. Take: - $I = G_x$, acting on itself by left multiplication; - $s_g(z) = \mu(\Gamma(g, g^{-1} * z), s_0(g^{-1} * z))$ on $U(x)$, and 0 off $U(x)$.

These are the terms of the average of Part XII. They are global sc⁺-sections supported in $\Phi(g)(\mathrm{supp}\, s_0) \subset V$. Their values `Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.ofSeed_s`: - $s_1 = s_0$ on $U(x)$ `Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.ofSeed_one`; - the family vanishes off V `Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.ofSeed_vanish`; - if $N(s_0(y)) \le b$ everywhere then $N(s_g(y)) \le b$ everywhere `Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.ofSeed_normW_le`, by invariance of N.

Equivariance, the text's (13.8), is $s_{gh}(g * z) = \mu(\Gamma(g, z), s_h(z))$. It follows from $\Gamma(g, h * z) \circ \Gamma(h, z) = \Gamma(gh, z)$ and the composition law of μ. The text's map $\tau : G_x \to \mathrm{Per}(G_x)$ is the left multiplication action.

Theorem 13.5.4 (1) (narrower), p. 632 `Chapter13/AtomicConstruction · SBLocalization.theorem_13_5_4_1`. Assume: - X admits bump functions in the pointwise reading; - x is smooth; - $U(x)$ is the domain of a natural representation with the properness property; - $V \ni x$ is open, invariant, with $\mathrm{cl}\, V \subset U(x)$; - $w \in W_x$ is smooth.

Then there is a symmetric family vanishing off V with $s_{i_0}(x) = w$ for some i_0.

Proof. 1. An auxiliary norm of Part I exists, by Proposition 5.1.3 (Part V). 2. Part I's Lemma 5.3.3 gives an sc⁺-section s_0 with $s_0(x) = w$, supported in V `Chapter5/BumpFunctions · lemma_5_3_3`. Its bump-function hypothesis on the object M-polyfold comes from the pointwise reading on the ep-groupoid, by Theorem 12.3.2 (1) (Part XII). This is the text's "construct in local coordinates an sc⁺-section … multiply by a bump function". 3. The family of the seed s_0, with $i_0 = 1$.

The cut-off Chapter13/AtomicConstruction · SBLocalization.exists_cutoff. For an sc⁺-section s on an open $O \ni x$ and an open $V \ni x$, there is an sc⁺-section s_0 of $W \to X$ with these properties: - it is supported in V; - it equals s near x; - it vanishes off $V \cap O$; - $N(s_0(y)) \le N(s(y))$ on O for every auxiliary norm N.

Proof. 1. Proposition 5.5.3 (Part V) gives an sc-smooth $\beta : X \to [0,1]$ with $\beta = 1$ near x and $\operatorname{supp}\beta \subset V \cap O$. 2. $s_0 = \beta \cdot s$, with s extended by zero off O. It vanishes where $\beta = 0$ Chapter13/AtomicConstruction · SBLocalization.sectionSmul_eq_fiberZero. 3. It is sc⁺: on O as a product of an sc-smooth function and an sc⁺-section, and off the closed support of β as the zero section. These two open sets cover X. 4. The norm bound: $N(\beta(y)s(y)) = |\beta(y)|N(s(y)) \le N(s(y))$.

The text asks for $\beta(x) = 1$ "with arbitrarily small support". The conclusion "$s_{i_0} = s$ near x" needs $\beta = 1$ near x, which Proposition 5.5.3 provides.

Theorem 13.5.4 (2) (narrower), p. 632 Chapter13/AtomicConstruction · SBLocalization.theorem_13_5_4_2. For an sc⁺-section s on an open $O \ni x$, there is a symmetric family vanishing off V with $s_{i_0} = s$ near x. *Proof*: the family of the seed given by the cut-off, with $i_0 = 1$.

Narrower only through the pointwise reading of bump functions, as in Theorem 12.3.3 (Part XII). The conclusions are stronger than printed: global sections, vanishing off V. The properness property in both parts, and the smoothness of x in (2), are kept and not used.

XIII.28 Theorem 13.5.5 (2017: Theorem 13.8): Construction II

Step 1: an invariant V Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.exists_vanishing_nbhd. For a symmetric family on $U(x)$ there is an open invariant $V \ni x$ with $\operatorname{cl} V \subset U(x)$ off which every section vanishes. 1. $K = \{x\} \cup \bigcup_i \operatorname{supp} s_i$ is closed, and lies in $U(x)$ since the supports do. 2. The object space is Hausdorff and paracompact, hence normal. There is an open $V_0 \supset K$ with $\operatorname{cl} V_0 \subset U(x)$. 3. $V = \bigcap_{g \in G_x} (U(x) \cap \Phi(g)^{-1}(V_0))$ is open, contains x, and is invariant. Its closure lies in $\operatorname{cl} V_0 \subset U(x)$. 4. Every section vanishes off V. Equivariance gives $s_{g(i)}(g * z) = 0$ iff $s_i(z) = 0$ Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.eq_zero_iff, since $\mu(\Gamma(g,z),\cdot)$ is injective and maps 0 to 0. A point $z \in U(x) \setminus V$ has some g with $g * z \notin V_0$. Then $g * z \notin \operatorname{supp} s_{g(i)}$, so $s_{g(i)}(g * z) = 0$ and $s_i(z) = 0$. A point outside $U(x)$ is outside every support.

This is condition (ii) of the text's proof, which takes such a $V(x)$ as given.

Step 2: the atomic data Chapter13/AtomicConstruction · SBLocalization.AtomicData.ofFamily. The family restricted to $U(x)$, with this V, is atomic data in the sense of §XIII.25. Global sc⁺-sections are sc⁺ on $U(x)$.

Theorem 13.5.5 (narrower), p. 633 Chapter13/AtomicConstruction · SBLocalization.theorem_13_5_5. For a symmetric family on $U(x)$, with $U(x)$ having the properness property and $I \neq \emptyset$, there is a unique Λ with these properties: - it is atomic; - it is trivial over the points outside the saturation of $U(x)$; - over $U(x)$, $\Lambda(w) = |I|^{-1}\#\{i : s_i(P(w)) = w\}$.

Proof. 1. *Existence.* The multisection of the data of step 2. It is atomic, by §XIII.25. It is trivial off the saturation of $\operatorname{cl} V$, which lies in the saturation of $U(x)$. Over $U(x)$ it is the count. 2. *Uniqueness.* Let Λ have the three properties, and w a vector. - If $P(w)$ is reachable through φ, then $\Lambda(w) = \Lambda(\mu(\varphi, w))$, since Λ is a functor. That is the count, by the third property. - Otherwise $P(w)$ is outside the saturation of $U(x)$, and Λ is trivial there by the second property.

In both cases $\Lambda(w)$ is the value of the multisection of the data.

Narrower by $I \neq \emptyset$. The text does not state it, and the printed formula presupposes it. With $I = \emptyset$ the formula gives $\Lambda = 0$ on all vectors over $U(x)$, which is not an sc⁺-multisection, since the weights over a point sum to 1. For atomic Λ it is automatic (§XIII.25), and the families of Construction I have $I = G_x$ (§XIII.27).

"Supported in the saturation of $U(x)$" is read as triviality over the points not isomorphic to a point of $U(x)$. This is the text's definition of Λ off the reachable points. Bump functions and the smoothness of x are kept and not used.

The last clause: Λ is structurable (narrower), p. 633 `Chapter13/AtomicStructurable · SBLocalization.theorem_13_5_5_structurable`. Given a good system, the atomic Λ of Construction II is structurable. It is the parametric form of §XIII.26 `Chapter13/AtomicStructurableLocal · SBLocalization.theorem_13_5_5_structurable_hyp` with Theorem 13.5.3 substituted, as the text derives it ("We have already established that they are structurable"). The added hypothesis is that of Theorem 13.5.3, with the same witness.

XIII.29 Theorem 13.5.6 (2017: Theorem 13.9): atomic multisections through a vector, and with a bound

Two facts about the multisection of atomic data. - *A norm bound* `Chapter13/AtomicConstruction · SBLocalization.AtomicData.pointwiseNorm_mult_le`. If $N(s_i(z)) \leq b$ for all i and $z \in U(x)$, with $b \geq 0$, then the pointwise norm of Definition 13.2.3 (§XIII.8) satisfies $N(\Lambda)(y) \leq b$ for every y. Every vector with positive weight falls in one of two cases: - over a reachable point, it is $\mu(\varphi^{-1}, s_i(t\varphi))$ for some i, and N is invariant; - otherwise, it is 0. - *The local structure on $U(x)$* `Chapter13/AtomicConstruction · SBLocalization.AtomicData.isLocalRepOn_mult`. Over $U(x)$ the sections of the data, enumerated, with weights $|I|^{-1}$, are a local section structure of the multisection.

Theorem 13.5.6, first part (narrower), p. 634 `Chapter13/AtomicConstruction · SBLocalization.theorem_13_5_6_1`. Let $w \neq 0$ be smooth over x, and $U(x)$ the domain of a natural representation. Then there is an atomic Λ with: 1. dom-supp(Λ) in the saturation of $U(x)$; 2. $\Lambda(\mu(g, w)) > 0$ for every $g \in G_x$.

Proof. 1. Inside $U(x)$ choose a natural representation $U'(x)$ with the properness property and an invariant V with $\mathrm{cl}\, V \subset U'(x)$ (§XIII.25). 2. x is smooth, since w is. 3. Construction I (1) gives a family through w, vanishing off V. 4. Its atomic data give Λ, the multisection of the data, with $I = G_x$. 5. The domain support lies in the saturation of $\mathrm{cl}\, V$, so in that of $U(x)$. 6. $\Lambda(\mu(g, w)) = \Lambda(w)$, since Λ is a functor. That is the count at w, which is positive because $s_1(x) = w$.

The text's "$\pi^{-1}(U(x))$" is read as the saturation of $U(x)$, and "$\Lambda(g * w)$" as $\Lambda(\mu(g, w))$.

Theorem 13.5.6, second part (narrower), p. 634 `Chapter13/AtomicConstruction · SBLocalization.theorem_13_5_6_2`. Let N be an auxiliary norm, s an sc⁺-section on $U(x)$, and $\varepsilon > 0$. Then there is an atomic Λ with: 1. domain support in the saturation of $U(x)$; 2. $N(\Lambda)(y) \leq N(s(x)) + \varepsilon$ for all y; 3. a local section structure on an open $O \ni x$ one of whose sections equals s on O, with positive weight.

Proof. 1. Let $b = N(s(x)) + \varepsilon$. The set $O_1 = U(x) \cap \{N(s(\cdot)) < b\}$ is open and contains x: N is continuous on the level-1 part and s is sc⁺. 2. Inside O_1 choose $U'(x)$ and V as in the first part. 3. The cut-off of s on $U'(x)$ gives a seed s_0 equal to s near x. Its norm is $\leq N(s(y)) < b$ on $U'(x)$, and 0 elsewhere, so $\leq b$ everywhere. 4. The family of the seed keeps the bound, and its atomic data give Λ, with the norm bound by the first fact above. 5. Near x, $s_1 = s_0 = s$. The local structure on $U'(x)$, restricted to $U'(x) \cap O'$ with O' the set where $s_0 = s$, contains s with weight $|G_x|^{-1} > 0$.

"Whose local section structure near x contains s with positive weight" is read as the third property.

Both parts `Chapter13/AtomicConstruction · SBLocalization.theorem_13_5_6`. *Narrower* only through the pointwise reading of bump functions. The paracompactness of $|X|$ is kept and not used. The text uses it for the existence of N (Theorem 12.2.2), and here N is given.

XIII.30 Theorem 13.5.7 (2017: Theorem 13.10): decomposition into commensurable atomic pieces

Tools. - *The pieces as data over c* `Chapter13/AtomicSum · SBLocalization.CommData.smulFunOver`. For a structured tuple T and an sc-smooth function β invariant along morphisms, the sections βs_i^x are data over the choice c of T (§XIII.24) for $\beta \odot \Lambda$. This is Lemma 13.3.14 (§XIII.16), with the same index sets and correspondences. - *$\beta \odot \Lambda$ is trivial where $\beta = 0$* `Chapter13/AtomicSum · SBLocalization.multisectionSmulFun_of_eq_zero`. - *Shrinking in the orbit space* `Chapter13/AtomicSum · SBLocalization.exists_orbit_nbhd`. For a good system and a point x there is an open $O_x \ni |x|$ in $|X|$ with $\operatorname{cl} O_x \subset |U(x)|$. $|U(x)|$ is open, by Proposition 7.1.8, and $|X|$ is regular, by Lemma 7.3.5 (Part VII).

Theorem 13.5.7 (stronger), p. 635 `Chapter13/AtomicSum · SBLocalization.theorem_13_5_7`. If X has sc-smooth partitions of unity, then for every structured tuple $T = (\Lambda, \mathcal{U}, S, \tau)$ there are: - a locally finite family $(\Lambda_j)_{j \in X}$, each atomic on a neighbourhood with the natural action (§XIII.25); - data over the choice c of T for each Λ_j;

such that - the locally finite commensurable sum (§XIII.24) is Λ; - its sections are those of T on every $U(x)$; - its structured class is that of T.

Proof. 1. *A partition of unity.* For each x take O_x by the shrinking. The sets $\pi^{-1}(O_x)$ form an open saturated cover of X. Take an sc-smooth partition of unity of functors $(\beta_j)_{j \in X}$ subordinate to it, with $\operatorname{supp} \beta_j \subset \pi^{-1}(O_j)$. 2. *The pieces.* $\Lambda_j = \beta_j \odot \Lambda$, with data $\beta_j s_i^x$ over c. 3. *Locally finite* (Definition 13.2.12). Near each point only finitely many β_j are nonzero, and Λ_j is trivial where $\beta_j = 0$. The neighbourhoods can be taken saturated, because the β_j are functors. 4. *The sections.* $\sum_j \beta_j(y) s_i^x(y) = s_i^x(y)$, since $\sum_j \beta_j = 1$. The finite sum is that of §XIII.24, with the zero summands removed. 5. *The sum is Λ.* The counts of the same sections agree, and the count over c is Λ on every $U(x)$. 6. *Each piece is atomic* at $x_j = j$: - $U(j)$ with its natural action, and proper closure (good systems); - $V = U(j) \cap \pi^{-1}(O_j)$, open and invariant, with $\operatorname{cl} V \subset U(j)$ by Lemma 13.1.1 (§XIII.1); - sections $\beta_j s_i^j$, which vanish on $U(j) \setminus V$, where $\beta_j = 0$; - condition (3) at reachable points is the count of Λ_j transported along φ; - off the saturation of $U(j)$, $\beta_j = 0$, since $\operatorname{cl} O_j \subset |U(j)|$, so Λ_j is trivial. 7. *The classes are equal.* The commensurable sum's tuple and T have the same multisection, the same good system and the same index sets. Their correspondences agree after the identity relabelling. So they are equivalent in the sense of Definition 13.3.8, and their classes are equal.

The text's form `Chapter13/AtomicSum · SBLocalization.theorem_13_5_7_book`. For structurable Λ on X with paracompact $|X|$ and sc-smooth partitions of unity, Λ has a structured lift that is the locally finite commensurable sum of atomic pieces. Paracompactness is kept and not used.

Stronger: - the decomposition holds for every structured lift, not only one; - the class equality is literal, through the quotient by Definition 13.3.8; - the paracompactness of $|X|$ is not used, since regularity of $|X|$, which every ep-groupoid has, suffices for the shrinking.

The text's refinement $(V_j)_{j \in J}$ with points x_j is replaced by the index set X itself, with $V_j = O_j$. The

atomic pieces are atomic on neighbourhoods with the natural action, the extra reading of Definition 13.5.1. The sets of a good system need not be domains of natural representations.

XIII.31 What is not formalized

- No numbered statement of Chapter 13 is open. The chapter's gaps G.141, G.142, G.143, G.148, G.149 and G.163 are closed:
  - G.141: Theorem 13.1.7 as printed (§XIII.5);
  - G.142: decorated sc$^+$-multisections and their algebra (§§XIII.10–XIII.13);
  - G.143: no inverses (§XIII.11);
  - G.148: Proposition 13.3.19 (§XIII.18);
  - G.149: Theorem 13.5.3 and the last clause of Theorem 13.5.5 (§§XIII.26, XIII.28);
  - G.163: Proposition 13.4.2, in the reading of structured data relative to the open V (§XIII.21).
- Remark 13.3.13, the negative half. The claim is that the structured sums $\Lambda_1 \oplus \Lambda_2$ and $\Lambda_2 \oplus \Lambda_1$ differ, because $I_x^1 \times I_x^2$ and $I_x^2 \times I_x^1$ differ. It is a statement about inequality of types and has no formal counterpart. The positive half, that the two are related by the relabelling, is in §XIII.16.
- Remarks 13.3.9, 13.3.16 and 13.5.2 are prose.
- The text's sub-ep-groupoid $W|V$ in Proposition 13.4.2 is read as data relative to V inside W (§XIII.21). No strong bundle over an open full sub-ep-groupoid is built.

XIII.32 What the formalization taught us

§13.1 is a study of the bi-action. Once the bi-action is written as a formula, almost everything follows from two facts: - morphisms between points of a neighbourhood with the natural action are $\Gamma(g, \cdot)$ for a unique g; - s and t are injective on each component.

Lemma 13.1.6 (1) then needs one morphism with $g' * \psi \in \Sigma$, not $g' * \Sigma = \Sigma$. Proposition 13.1.9 follows from Lemma 13.1.6 with the action laws, without the smoothness argument of the text, and with uniqueness among all maps.

The phrase "carries the natural G_x-action" needed a decision. Proposition 13.1.3 shrinks to invariant subsets that need not be connected, so a neighbourhood with the natural action cannot be the connected domain of a natural representation. It is an invariant open subset of one. With that reading the section holds as printed.

In Lemma 13.1.1 the two directions use different halves of the hypotheses: properness one way, the natural action the other. The invariance of V is used by neither.

Theorem 13.1.7 holds in two forms. - With properness read in X, it needs neither the openness of Q nor the smallness of the closures of $U(y)$. - As printed, with properness read in the full subcategory on the open Q, the hypothesis is equivalent to properness in X together with $\mathrm{cl}_X U(q) \subset Q$. A limit of points of $U(q)$ outside Q is moved into Q by a local section of s, and properness in Q then places it in Q.

No sub-ep-groupoid structure is needed: the full subcategory is its set of morphisms, with the restricted source and target.

In §13.2 the multisection algebra is convolution. $\oplus$, scalar multiples and locally finite sums are all sums over decompositions of a vector in a fibre, and their local structures are sums of sections with products

of weights. A locally finite sum over infinitely many indices, which the text does not write out, is a sum over finitely supported families. Over $O(x)$ it is a finite convolution.

The decorations add one subtlety. The intersection $U'(x) \cap U''(x)$ of two neighbourhoods with natural actions need not carry one natural action for which both structures are symmetric. So the sum is decorated on a smaller neighbourhood inside it on which the two actions agree, which Definition 13.2.8 allows.

The absence of inverses is a one-line computation once a neutral element is fixed: a two-valued multisection convolved with anything gives weight at most $\frac{1}{2}$ to the zero vector.

§13.3 is mostly combinatorics of finite index sets, and two points needed care. - The text writes equalities of index sets ($I'_x = \{*\}$, $I'_x = I_x$) where a formalization has bijections. The correspondences are compared after transport along them. - The tight version of Proposition 13.3.15 needs a compatibility the text does not check. It holds because every section of a structure vanishes where Λ is trivial.

Definition 13.3.8 as printed puts no condition on the sections. Presumably they are meant to agree as in Definition 13.2.8; nothing proved depends on it.

Products of infinitely many correspondences are well defined only because, near any two points, all but finitely many factors are the unit diagram $[\{*\} \leftarrow \{*\} \rightarrow \{*\}]$. The text's "left to the reader" in Proposition 13.3.19 is this bookkeeping. With the tight versions over a common good system, it is about five hundred lines.

§13.4 is simpler than printed. - The pull-back needs only F injective on $U(x)$ with $F(U(x)) \subset U'(F(x))$, not the equality the text arranges. The canonicity it asserts is a short argument once the pull-back is written as a map of structured classes. - The push-forward does not need Proposition 13.4.2. Every point of X', in $F(X)$ or not, gets a chart along a morphism $F(x_y) \to y$, which merges the text's two steps. The lifted morphisms are continuous because F is faithful and a local sc-diffeomorphism. - Proposition 13.4.2 is then the same chart for the identity equivalence. The text's three cases for the correspondences, with the maps A, C and a pseudo-inverse, are one formula: the correspondence of the lifted morphism. - The commensurable sum of Definition 13.4.5 is well defined because the count is transported along correspondences: $p|I_x| = q|I_{x'}| = |I|$ for the fibre sizes p, q of the two legs.

In §13.5 the atomic multisection is determined by its data. The count in Definition 13.5.1 (3) does not depend on the morphism used, and its local structure near any point is the given sections transported by a local inverse of t. What the text does not say is that the index set must be nonempty, since the weights of a multisection sum to 1.

In Theorem 13.5.3 the action of G_y on the index set comes from a single function H. It assigns to a morphism the element of G_{x_0} the morphism becomes after both ends are transported into $U(x_0)$. H is functorial, and locally constant because G_{x_0} is finite and X Hausdorff. Every compatibility follows from these two properties. Using the index set I_{x_0} everywhere, with zero sections where Λ is trivial and the full correspondence across the frontier of the saturation, avoids the case distinction of the text's $\{*\}$. The theorem needs a good system and nothing else: structurability is equivalent to the existence of one.

Theorem 13.5.7 needs regularity of $|X|$ for its shrinking, which every ep-groupoid has, and partitions of unity, not paracompactness. Its atomic pieces are atomic on neighbourhoods with the natural action, since the sets of a good system need not be connected domains of natural representations.

Part XIV. Extension of sc⁺-multisections (HWZ Chapter 14, §§14.1–14.6)

Chapter 14 (Springer 2021, pp. 637–682; 2017 numbers in parentheses) proves the ∂-extension theorem: a structurable sc⁺-multisection functor $\Lambda : W|\partial X \to \mathbb{Q}^+$ over the boundary of a tame ep-groupoid extends to a structurable $\Lambda' : W \to \mathbb{Q}^+$ on the whole bundle, with prescribed support and with its size bounded by a given function. It is the tool that makes the transversality theory of Chapter 15 work relative to the boundary, and through Chapter 16 relative to the boundary of a polyfold. §14.1 introduces good neighbourhoods of boundary points, sc⁺-multisections over ∂X and their structured versions, and states the theorem (Proposition 14.1.1, Definitions 14.1.2, 14.1.3, Proposition 14.1.4, Definition 14.1.5, Theorem 14.1.6, Definition 14.1.7, Proposition 14.1.8, Theorem 14.1.9, Remark 14.1.10 (2017: the discussion before Definition 14.1, Definitions 14.1, 14.2, Remark 14.2, Definition 14.3, Theorem 14.1, Definition 14.4, Proposition 14.1, Theorem 14.2, Remark 14.3)). §14.2 replaces a structured representative by one whose correspondences have separated level sets (Lemmas 14.2.1, 14.2.2, Proposition 14.2.3 (2017: the text before Lemma 14.1, Lemma 14.1, Proposition 14.2)). §14.3 extends the correspondences from the boundary morphisms to open sets of morphisms and covers ∂X by sets $\widehat{V}_a$ on which the extensions are defined (Lemma 14.3.1, Definition 14.3.2, Lemma 14.3.3, Proposition 14.3.4, Remark 14.3.5, Lemmas 14.3.6, 14.3.7, Proposition 14.3.8 (2017: Lemma 14.2, the text before Lemma 14.3, Lemma 14.3, Proposition 14.3, Remark 14.4, Lemmas 14.4, 14.5, Proposition 14.4)). §14.4 records, through z-loops, which boundary sections are forced to agree, and extends the boundary sections near each $\widehat{V}_a$ respecting these identifications (Remark 14.4.1, Definitions 14.4.2–14.4.4, Lemma 14.4.5, Proposition 14.4.6, Lemma 14.4.7, Definition 14.4.8, Lemma 14.4.9, Proposition 14.4.10, Definition 14.4.11, Remark 14.4.12, Lemma 14.4.13, Proposition 14.4.14 (2017: Remark 14.5, Definitions 14.5–14.7, Lemma 14.6, Proposition 14.5, Lemma 14.7, Definition 14.8, Lemma 14.8, Proposition 14.6, Definition 14.9, Remark 14.6, Lemma 14.9, Proposition 14.7)). §14.5 cuts the local extensions off, transports them along morphisms, sums them and assembles the extension, using a structurability criterion (Lemmas 14.5.1, 14.5.2, Remark 14.5.3, Proposition 14.5.4, Theorem 14.5.5 and the end of the proof of Theorem 14.1.9 (2017: Lemmas 14.10, 14.11, Remark 14.7, Proposition 14.8, Theorem 14.3)). §14.6 builds boundary data face by face for inductive constructions (Definitions 14.6.1, 14.6.2, Theorem 14.6.3 (2017: Definitions 14.10, 14.11, Theorem 14.4)). This Part follows the book: §14.1 in §§XIV.1–XIV.7, §14.2 in §XIV.8, §14.3 in §§XIV.9–XIV.12, §14.4 in §§XIV.13–XIV.20, §14.5 in §§XIV.21–XIV.24, the proof of Theorem 14.1.9 in §XIV.25 with a witness with boundary in §XIV.26, §14.6 in §§XIV.27–XIV.28; then what is not formalized (§XIV.29) and what the formalization taught us (§XIV.30).

What is proved, and what is not. The ∂-extension theorem, Theorem 14.1.9, is proved with two readings made explicit: the strong bundle has a tame strong bundle chart at every object, which is how "a strong

bundle over a tame ep-groupoid" is read throughout Part XII and here, and Λ charges every boundary fibre, which is what the factor $|I_x|^{-1}$ of Definition 14.1.3 presumes; the second condition is also necessary (§§XIV.7, XIV.25). Every step of the construction of §§14.2–14.5 is proved, for the objects the construction itself produces, with no hypothesis beyond the text's; the half-space bundle $[0,\infty)\times\mathbb{R}^m\times\mathbb{R}^k$ with a constant non-zero section over its boundary satisfies all hypotheses of the theorem jointly (§XIV.26). *§14.1.* Proposition 14.1.1 is proved as printed, by Part I's abstract face calculus instead of a chart computation (§XIV.1); Definition 14.1.2 is formalized, and the remark after it, that the faces $\bar{\theta}_j$ are tame M-polyfolds, is proved (§XIV.1). Definition 14.1.3 is formalized with condition (1) read through the tame strong bundle charts of X (§XIV.2). Proposition 14.1.4 is proved, with the two standing assumptions named (§XIV.3). Theorem 14.1.6 is proved with tameness of X and paracompactness of $|X|$, which its proof uses, in place of the printed paracompactness of $|\partial X|$ (§XIV.4). Definition 14.1.7 is formalized (§XIV.5). Proposition 14.1.8 is proved in a stronger form: in its interior case and over ∂X, along generalized strong bundle isomorphisms and their classes, without the paracompactness of the orbit spaces (§XIV.6). Remark 14.1.10 is prose. *§14.2.* Lemmas 14.2.1, 14.2.2 and Proposition 14.2.3 are proved as printed (§XIV.8). *§14.3.* Lemma 14.3.1 is proved in a stronger form, the extended sets being symmetric under inversion; Definition 14.3.2 is formalized; Lemma 14.3.3 and Proposition 14.3.4 are proved as printed, the diagonal property of Proposition 14.3.4 by an argument the text does not give (§§XIV.9–XIV.10). Lemma 14.3.6 and Proposition 14.3.8 are proved with the facts their proofs use made explicit, and Lemma 14.3.7 in a stronger form (§§XIV.11–XIV.12). *§14.4.* The setting of §14.4 is built from the objects of §14.3 (§XIV.13). Definitions 14.4.2–14.4.4 and 14.4.8 are formalized, with the equivalence-relation properties the text asserts proved; Lemmas 14.4.5 and 14.4.7 are proved (§§XIV.14–XIV.15). Proposition 14.4.6 is proved, (1) without Lemma 14.4.7, (2) in a stronger form, for loops at points of $\widehat{V}_a$ and limit points in $\mathrm{cl}_X(\widehat{V}_a)\cap\partial X$ (§§XIV.15–XIV.16). Lemma 14.4.9, Proposition 14.4.10 and the existence in Definition 14.4.11 are proved, (3) of the lemma in a stronger form (§§XIV.17–XIV.18). Lemma 14.4.13 is proved, its (2) for points of $\mathrm{cl}_X(V_a)$ (§XIV.19). Proposition 14.4.14 is proved by a construction different from the text's (gluing by an ordinary partition of unity, then averaging over G_a), for the objects of §14.3 (§XIV.20). *§14.5.* Lemma 14.5.1 is proved in a stronger form, without tameness, and (14.53) holds for the cover of §14.3 itself, without shrinking (§XIV.21). Lemma 14.5.2 is proved in the form the proof of Theorem 14.1.9 uses it, an identity for the summed sections (§XIV.22). Proposition 14.5.4 is proved, its input carrying the property of the cut-offs that Lemma 14.5.1 (1) gives (§XIV.23). Theorem 14.5.5 is proved in a stronger form, without its properness and closure conditions (§XIV.24). *§14.6.* Faces are Part XI's ep-faces; Definitions 14.6.1 and 14.6.2 are formalized, sc^+ on a face and on a corner read through the charts of X; the restriction of Definition 14.6.1 is sc^+ on the corner; every structured sc^+-multisection on a face has a representative whose neighbourhoods satisfy (1) and (3) of a good system inside the face (§XIV.27). Theorem 14.6.3 is proved for representatives that agree on the intersections of faces, its extension part from Theorem 14.1.9 (§XIV.28). *Open* (§XIV.29): G.172 (the multisection form of Lemma 14.5.2, about 120 lines, unused), G.173 (Theorem 14.6.3 from a class-level compatible assignment), G.185 (condition (2) of a good system on a face, unused) and G.186 (the two readings of Theorem 14.1.9 built into the definitions or derived). No statement of Chapter 14 was found not to hold as we read it. One property of our own formalization is recorded in a remark (§XIV.7): the formal Definition 14.1.3 admits empty index sets, and a Lean statement of Theorem 14.1.9 without the charging condition does not hold when $\partial X\neq\emptyset$.

Decisions that shape the chapter.

- *The boundary.* ∂X is the set of objects with degeneracy index $d_X\geq 1$. It is closed, and saturated because the index is invariant along morphisms; sets open in ∂X are written $O\cap\partial X$ with O open in X. Good neighbourhoods are neighbourhoods of the object space, with the natural action of

Part XIII, and $U(x) = V(x) \cap \partial X$.

- *Sc⁺ on faces through the charts of X.* "$s|\bar{\theta}_j$ is sc⁺" in Definition 14.1.3 (1) is read as: in every tame strong bundle chart of W, at every point of $U(x)$, the local representative of s is sc⁺ on every local face germ $\{t_i = 0\}$ of the model, the condition of Part I's Definition 5.4.1 with ∂X replaced by $U(x)$. In a tame chart the germs of the $\bar{\theta}_j$ at a point are exactly these local faces, so no sub-M-polyfold structure on the $\bar{\theta}_j$ is needed. §14.6 reads sc⁺ on a face F, and on a corner $F \cap F'$, in the same way.
- *The standing assumptions.* "A strong bundle over a tame ep-groupoid" supplies tame strong bundle charts; it is formalized as the hypothesis that every object lies in a tame strong bundle chart, as in Part XII. "X admits sc-smooth partitions of unity" is Definition 5.5.1 for the object M-polyfold. Tameness of X and paracompactness of $|X|$ are assumed where a proof uses them; each result says which it uses.
- *Index sets.* The formal Definition 14.1.3 allows $I_x = \emptyset$. Theorem 14.1.9 is stated with the condition that Λ charges every boundary fibre, which for a structured Λ is the same as $I_x \neq \emptyset$ and is necessary for the conclusion.
- *Abstract steps, concrete instance.* Each step of §§14.3–14.5 is proved over a structure that names the data and the facts of the previous steps it uses (the z-loop setting, the boundary sections, the limit setting, the local extension data, the transport input, the assembly input, the criterion data), and then instantiated by the objects the construction produces from a structured representative. The final theorem takes no hypothesis on these structures.
- *z-loops with their arcs.* A z-loop and a z-arc along it are one inductive predicate, built by appending one morphism and one index step at a time. Concatenation, reversal, the action of G_a, the deformation of Proposition 14.4.6 and the transport of Proposition 14.5.4 are inductions on it.
- *Averaging.* Equivariance is obtained by averaging over the whole isotropy group, $\bar{s}_j(y) = |G_x|^{-1} \sum_g \mu(\Gamma(g^{-1}, g * y), s_{g(j)}(g * y))$, in Proposition 14.1.4 and in Proposition 14.4.14, instead of the text's averaging over a stabilizer and transport along an orbit.
- *Faces in §14.6* are Part XI's ep-faces X_θ (Definition 11.1.3). Theorem 14.6.3 takes chosen representatives that agree on the intersections of faces.

Map. All files are in `Polyfold/Chapter14`.

- *Good neighbourhoods of boundary points.* `GoodBoundary`: faces of an open set at a boundary point, good neighbourhoods, Proposition 14.1.1, Definition 14.1.2 (§XIV.1). `FaceTame`: the faces $\bar{\theta}_j$ of a good neighbourhood as faces of a face-structured open set, sub-M-polyfolds, tame M-polyfolds (§XIV.1).
- *Sc⁺-multisections over ∂X.* `BoundaryMultisection`: face-wise sc⁺ sections, Definition 14.1.3, Definition 14.1.5, Theorem 14.1.6, the averaging of Proposition 14.1.4 (§§XIV.2–XIV.4). `BoundaryStructured`: decorations, correspondences, structured tuples and their equivalence, Definition 14.1.7, the boundary domain support, the uncharged Lean statement of Theorem 14.1.9 (§§XIV.5, XIV.7). `EmptyIndex`: charging, empty index sets, necessity of charging (§§XIV.2, XIV.7).
- *Proposition 14.1.4.* `LocalExtension`: the local extension at a point and the gluing over an open set with closure inside V. `OpenExtension`: the extension on the open set itself, Proposition 14.1.4, the witness $\mathbb{R}^n \times \mathbb{R}^k$ (§XIV.3).
- *Proposition 14.1.8 over ∂X.* `BoundaryPull`, `BoundaryPush`: pull-backs and push-forwards of boundary structures, conditional on the transport of Definition 14.1.3 (1). `FaceTransport`, `FacePush`: that transport, and Proposition 14.1.8 for representatives and for classes (§XIV.6).
- *§14.2.* `GoodStructured`: Lemmas 14.2.1, 14.2.2, (P4), Proposition 14.2.3 (§XIV.8).
- *§14.3.* `ExtendCorrespondences`: (P5), Lemma 14.3.1, Definition 14.3.2, Lemma 14.3.3, Proposition

14.3.4 (§§XIV.9–XIV.10). `BoundaryCover`: saturated sets, Lemmas 14.3.6, 14.3.7, and Lemma 14.5.1 (§§XIV.11, XIV.21). `CoverVHat`: (P6), Proposition 14.3.8 (§XIV.12).

- *§14.4.* `ZLoops`: the z-loop setting, z-loops with arcs, Definitions 14.4.2–14.4.4, Lemma 14.4.5 (§XIV.14). `FiniteRepresentation`: Lemma 14.4.7 (§XIV.15). `ZLoopDeform`: the setting with topology, Proposition 14.4.6 (1) (§XIV.15). `ZRelationClosure`: equivariant neighbourhoods, Definition 14.4.8, Lemma 14.4.9 (1), (2), (4) (§XIV.17). `ZLoopCoherent`: boundary sections, Proposition 14.4.6 (2) at points of V_a and as a statement, Lemma 14.4.9 (3), Proposition 14.4.10, Definition 14.4.11, Lemma 14.4.13 (§§XIV.16–XIV.19). `ZLoopLimits`, `ZLoopLimitExists`: the limit argument, Proposition 14.4.6 (2) and its consequences (§§XIV.16–XIV.18, XIV.20). `CoherentExtension`: Definition 14.4.11 in the form Proposition 14.4.14 consumes, Proposition 14.4.14 (§XIV.20). `ZDataLocalExtension`: Proposition 14.4.14 for the boundary sections (§XIV.20). `ZLoopSetting`: the setting of §14.4 from the objects of §14.3, and all of §14.4 for them (§§XIV.13, XIV.16–XIV.20).
- *§14.5 and Theorem 14.1.9.* `TransportStatement`: the input and the statement of Proposition 14.5.4. `TransportProof`: Proposition 14.5.4 (§XIV.23). `TransportedSum`: the assembly input, the summed sections, the identity of Lemma 14.5.2 (§XIV.22). `StructurabilityCriterion`: Theorem 14.5.5 (§XIV.24). `ExtensionAssembly`: the functor Λ', the criterion data, the extension (§XIV.25). `Norm–Control`: norms of multisections, the size control (§XIV.25). `AssemblyInputInstance`: (14.53) for the cover of §14.3, Lemma 14.5.1 for it, the data of §§14.3–14.5 for every charging Λ (§§XIV.21, XIV.25). `BoundaryExtensionTheorem`: Theorem 14.1.9 and the extension part of Theorem 14.6.3 (§§XIV.7, XIV.25, XIV.28).
- *A witness with boundary.* `HalfSpaceBundle`: the half-space bundle as a strong bundle over an ep-groupoid, with all standing hypotheses. `HalfSpaceConstSection`: sc$^+$-sections satisfy Definition 14.1.3 (1); the multisection of a constant section; Theorem 14.1.9 applied (§§XIV.2, XIV.26).
- *§14.6.* `FaceGerm`: faces through a boundary point, sc$^+$ relative to a face, the gluing criterion. `FaceStructured`: structured data over a set, Definitions 14.6.1, 14.6.2. `CornerScPlus`: sc$^+$ on a corner. `FaceGoodSystem`: good systems on a face (§XIV.27). `FaceAssembly`: Theorem 14.6.3 (§XIV.28).

Throughout, $(P : W \to X, \mu)$ is a strong bundle over an ep-groupoid X (an object of the category of strong bundles over ep-groupoids of Part X) with source and target maps s, t, orbit map $\pi : X \to |X|$, isotropy groups G_x, and $\mu(\varphi, \cdot) : W_{s(\varphi)} \to W_{t(\varphi)}$ the fibre action. A neighbourhood with the natural action, $(U(x), \Phi, \Gamma)$, is Part XIII's: an open $U(x) \ni x$ with an action $\Phi_g = g * \cdot$ of G_x by sc-diffeomorphisms and morphisms $\Gamma(g, y) : y \to g * y$ that are all the morphisms between points of $U(x)$. A set B of objects is saturated if $s(\varphi) \in B$ iff $t(\varphi) \in B$. For sets U, U' of objects, $\mathcal{U}(U, U') = \{\varphi : s(\varphi) \in U,\ t(\varphi) \in U'\}$, and $\mathcal{U}(x, x')$ when the sets are those of x and x'. Index correspondences $J(x, x')$, their bi-action $h * [d] * g$, the swap $[d]^\sharp$ and the correspondences $[I \xleftarrow{\mathrm{id}} I \xrightarrow{g} I]$ are Part XIII's (Definition 13.3.4); a *pair* of a correspondence $[I \xleftarrow{a} K \xrightarrow{b} I']$ is $(a(k), b(k))$ for some $k \in K$ `Chapter14/ZLoops · SBLocalization.IndexCorr.Pairs`, and a relation holds for a correspondence when it holds on all its pairs `Chapter14/TransportProof · SBLocalization.IndexCorr.sat_of_pairs_t9` `Chapter14/TransportProof · SBLocalization.IndexCorr.rel_of_sat_t9`; every index of the right-hand set has a partner `Chapter14/TransportProof · SBLocalization.IndexCorr.exists_pairs_left_t9`. The pairs of $[d]^\sharp$ are the reversed pairs of $[d]$ `Chapter14/ZLoops · SBLocalization.IndexCorr.pairs_swap`, and those of $[\mathrm{id}, g]$ are the $(i, g(i))$ `Chapter14/ZLoops · SBLocalization.IndexCorr.pairs_ofPerm`. Two fibre-action identities are used everywhere: $\mu(\psi \circ \gamma, v) = \mu(\psi, \mu(\gamma, v))$ `Chapter14/BoundaryMultisection · SBLocalization.fibAct_comp_p3w3` and $\mu(1_y, v) = v$ `Chapter14/BoundaryMultisection · SBLocalization.fibAct_unit_p3w3`.

XIV.1 Proposition 14.1.1, Definition 14.1.2 and the remark after it (2017: the discussion before Definition 14.1, Definition 14.1): good neighbourhoods of boundary points

Faces at a point. For $x \in \partial X$ and an open set $V \ni x$, *faces of V at x* are sets $\theta_1, \dots, \theta_{d_X(x)}$ `Chapter14/GoodBoundary · EpGroupoid.HasBoundaryFaces` that are pairwise distinct connected components of $\{y \in V : d_X(y) = 1\}$, whose closures $\bar{\theta}_i = V \cap \operatorname{cl}\theta_i$ in V contain x, and with the counting formula $d_X(y) = \#\{i : y \in \bar{\theta}_i\}$ for $y \in V$. The formula gives (4)(c) of the proposition, $V \cap \partial X = \bigcup_i \bar{\theta}_i$ `Chapter14/GoodBoundary · EpGroupoid.HasBoundaryFaces.inter_boundary_eq`: a point of V lies in ∂X iff its count is positive.

Proposition 14.1.1 (same) `Chapter14/GoodBoundary · EpGroupoid.proposition_14_1_1`, p. 638. *Statement*: let X be tame, $x \in \partial X$ and $W \ni x$ open. There is an open $V(x) \subset W$ with the natural G_x-action such that (1) $V(x)$ and $V(x) \cap \partial X$ are connected, (2) the natural action is defined on $V(x)$, (3) $t : s^{-1}(\operatorname{cl}_X V(x)) \to X$ is proper, and (4) there are faces $\theta_1, \dots, \theta_{d_X(x)}$ of $V(x)$ at x, with $V(x) \cap \partial X = \bigcup_i \bar{\theta}_i$. "Arbitrarily small" is read as "inside every open $W \ni x$". The 2017 text states this inside the discussion before Definition 14.1; the 2021 edition gives a proof in a tame chart.

Proof. The Lean proof is the relative form `Chapter14/GoodBoundary · EpGroupoid.exists_isGoodBoundaryNbhd_le`: given a neighbourhood N of x with the natural action and t proper on $s^{-1}(\operatorname{cl} N)$, and an open $W \ni x$, there is a good $V \subset N \cap W$ carrying the action of N. The proposition follows by taking N from Part XIII (Theorem 7.1.13 with the properness of Lemma 13.1.2), and the relative form is what refinements of good systems need (§§XIV.4, XIV.8). It does not follow the text's chart computation; it uses Part I's abstract face calculus, which works for any function d satisfying the corner axioms, and the degeneracy index of a tame M-polyfold does `Chapter2/TameBoundary · MPolyfold.isCornerIndex_degIndex`.

1. *A neighbourhood all of whose open subsets are face-structured.* Part I provides an open $D \ni x$ such that every open subset of D is a face-structured open set in the sense of Definition 2.7.6 `Chapter2/TameBoundary · TameBoundary.exists_nbhd_forall_isFaceStructuredOpen`.
2. *Shrink inside $W \cap D$.* Restrict N to an invariant neighbourhood $N' \subset N \cap W \cap D$ with the same action `Chapter13/GoodSystem · EpGroupoid.NatNbhd.exists_restrict_subset`; the properness passes to subsets.
3. *The centred part.* Let $V_1 = \operatorname{reach}(N', x)$, the set of $y \in N'$ such that every face of N' through y contains x `Chapter2/TameBoundary · TameBoundary.reach`. It is open `Chapter2/TameBoundary · TameBoundary.isOpen_reach` and centred at x, every face of V_1 containing x `Chapter2/TameBoundary · TameBoundary.isCenteredAt_reach`. It is invariant under the natural action: each Φ_g is a homeomorphism of N' preserving d_X and fixing x, so it maps the faces through y onto the faces through $g * y$ `Chapter7/TameBoundaryEp · TameBoundary.IsDHomeoOn.facesThrough_image`, and the condition "every face through y contains x" is carried to $g * y$. That the natural action preserves d_X is `Chapter14/GoodBoundary · EpGroupoid.NatNbhd.degIndex_Φ`.
4. *The component.* Let V be the connected component of x in V_1. It is open (components of open sets in the locally connected object space are open) and invariant: $\Phi_g(V)$ is connected, contains $\Phi_g(x) = x$, and lies in V_1, hence in V.
5. *V is centred and face-structured.* The component of a centred set is centred `Chapter14/GoodBoundary · TameBoundary.isCenteredAt_connectedComponentIn`, and the faces of V are the traces of those of V_1: for $p \in V$, the component of p in $V \cap \{d = 1\}$ is its component in $V_1 \cap \{d = 1\}$ `Chapter14/GoodBoundary · TameBoundary.connectedComponentIn_inter_deg_of_mem_cc`. V is face-structured by step 1.

6. *The faces θ_i.* Since V is centred and face-structured, the faces of V through x are $d_X(x)$ in number; enumerate them through an equivalence with $\{1, \dots, d_X(x)\}$ and let θ_i be the component of $V \cap \{d = 1\}$ at a chosen point of the i-th face. The counting formula is the face-structured property of V, and $x \in \bar{\theta}_i$ is centredness.
7. *Connectedness of $V \cap \partial X$.* By (4)(c), $V \cap \partial X = \bigcup_i \bar{\theta}_i$ (together with x); each face is preconnected `Chapter14/GoodBoundary · TameBoundary.isPreconnected_faceAt` and all contain x, so the union is preconnected.
8. *Properness.* t is proper on $s^{-1}(\operatorname{cl} V)$ because $\operatorname{cl} V \subset \operatorname{cl} N$ is closed and t is proper on $s^{-1}(\operatorname{cl} N)$ `Chapter7/ProperMaps · isProperMap_domRestrict_of_subset_of_isClosed`.

The text's argument builds the set Q in a tame chart with $\partial C \cap Q = \Theta$; the face calculus replaces it and gives the same four properties.

Definition 14.1.2 (restated) `Chapter14/GoodBoundary · EpGroupoid.IsGoodBoundaryNbhd`, p. 641. A neighbourhood $V(x)$ with the natural G_x-action is a *good open neighbourhood of x in X* if (1) $V(x)$ and $V(x) \cap \partial X$ are connected, (3) t is proper on $s^{-1}(\operatorname{cl}_X V(x))$, and (4) faces at x exist; the *good open neighbourhood in ∂X* is $U(x) = V(x) \cap \partial X$ `Chapter14/GoodBoundary · EpGroupoid.NatNbhd.bdry`. *Restated*: the text phrases the definition through $U(x)$; the formal one is on $V(x)$, of which $U(x)$ is the trace, because every later use (Definition 14.1.5, Proposition 14.1.4, §14.3) needs $V(x)$. "Admits the natural G_x-action" is read as carrying one, which is how Part XIII reads the same words. The remarks after the definition are proved: $U(x) = \bigcup_i \bar{\theta}_i$ `Chapter14/GoodBoundary · EpGroupoid.IsGoodBoundaryNbhd.bdry_eq`; $U(x)$ is invariant under the natural action `Chapter14/GoodBoundary · EpGroupoid.NatNbhd.mapsTo_Φ_bdry`, since the action preserves d_X; and only boundary points have good neighbourhoods `Chapter14/GoodBoundary · EpGroupoid.IsGoodBoundaryNbhd.mem_boundary`: for $d_X(x) = 0$ the counting formula forces $V \cap \partial X = \emptyset$, which is not connected in the sense that requires non-emptiness. Good neighbourhoods exist inside every open $W \ni x$ `Chapter14/GoodBoundary · EpGroupoid.exists_isGoodBoundaryNbhd`, the witness of the definition at every boundary point of a tame X.

The remark after Definition 14.1.2 (same) `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.face_isTame`, p. 641: for X tame, the $\bar{\theta}_j$ are tame M-polyfolds. *Proof.* Fix V open with faces $\theta_1, \dots, \theta_{d_X(x)}$ at x.

1. *The $\bar{\theta}_i$ are the faces of V.* A point of V with $d_X = 1$ in $\operatorname{cl} \theta_i$ lies in θ_i, a component of $V \cap \{d = 1\}$ being closed in it `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.mem_of_mem_closure`; so $\bar{\theta}_i$ is the face of V through any point of θ_i `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.eq_faceAt`, hence a face of V in the sense of Definition 2.7.6 `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.isFaceIn`, and every face of V is one of them `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.isFaceIn_iff`. They are pairwise distinct `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.injective_closure`, and the faces of V through y are the $\bar{\theta}_i \ni y$ `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.facesThrough_eq`.
2. *V is face-structured.* The counting formula of (4) is the face-structured condition, so V is a face-structured open set `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.isFaceStructuredOpen`. Two bridge lemmas identify Definition 2.5.10 (faces of an M-polyfold) with Definition 2.7.6 (faces of an open set) on the whole space `Chapter14/FaceTame · MPolyfold.isFace_iff_isFaceIn_univ` `Chapter14/FaceTame · MPolyfold.isFaceStructured_iff_univ`; with them, the M-polyfold V (Part I's restriction to an open set) is face-structured `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.isFaceStructured_restrictOpen` and each $\bar{\theta}_i$ is one of its faces `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.isFace_restrictOpen`.
3. *Tameness.* Part I's Theorem 2.5.17 (a face of a tame face-structured M-polyfold is a tame M-polyfold, with $d = d_F + 1$ on it) applied to $\bar{\theta}_i \subset V$ gives the remark.

Each $\bar{\theta}_i$ is also a sub-M-polyfold of X `Chapter14/FaceTame · EpGroupoid.HasBoundaryFaces.isSubMPolyfold`, stated for good neighbourhoods `Chapter14/FaceTame · EpGroupoid.IsGoodBoundaryNbhd.faces_isSubMPolyfold`. That this

structure agrees with the one as a face of V is not stated, though both come from the same local face charts. Only the tameness of X is assumed. Nothing in §§14.1–14.5 uses the remark: Definition 14.1.3 (1) is read in the charts of X (§XIV.2), and so is sc$^+$ on a face in §14.6 (§XIV.27).

XIV.2 Definition 14.1.3 (2017: Definition 14.2): sc$^+$-multisections over ∂X

Face-wise sc$^+$ sections `Chapter14/BoundaryMultisection · SBLocalization.IsFaceScPlusSectionOn`. Condition (1) of Definition 14.1.3 asks that "$s_i^x|\bar\theta_j$ is an sc$^+$-section of $W|\bar\theta_j$" for every face $\bar\theta_j$ of $U(x)$. Formally, a map s from objects to W is *face-wise sc$^+$ on a set U* if (a) for $y \in U$, $P(s(y)) = y$ and $s(y) \in W_{0,1}$, and (b) for every tame strong bundle chart c of W, every tame presentation T of its corner, $C = T^{-1}(\text{quadrant})$, every $y \in U$ in the chart's domain and every index i with $t_i(T\varphi(y)) = 0$, the local representative of s is sc$^+$ on the local face germ $\{t_i = 0\}$ near $\varphi(y)$: some neighbourhood of $\varphi(y)$ meets the face in an sc-retract, and the representative restricted to it is an sc$^+$-section there (Part XII's notion `IsScPlusOnFaceNear`). This is Part I's Definition 5.4.1 (an sc$^+$-section over ∂X) with ∂X replaced by U. *Reading*: at a point of $U(x)$ the germs of the $\bar\theta_j$ through it are, in a tame chart, exactly the local faces $\{t_i = 0\}$ through its image, so (b) says that the restriction to each $\bar\theta_j$ is sc$^+$ for the structure the $\bar\theta_j$ inherit from the charts, without building that structure. The condition is monotone in U `Chapter14/BoundaryMultisection · SBLocalization.IsFaceScPlusSectionOn.mono` and pointwise in U `Chapter14/FaceTransport · SBLocalization.isFaceScPlusSectionOn_iff_singleton`; it depends only on the values of s on ∂X near U, because a local face of a tame chart is mapped by the chart inverse into ∂X `Chapter14/BoundaryPull · SBLocalization.symm_mem_boundary_fm` `Chapter14/BoundaryPull · SBLocalization.IsFaceScPlusSectionOn.congr_fm`, and since the representative near a point only sees the section on a neighbourhood `Chapter14/BoundaryPull · IsScPlusOnFaceNear.congr_open_fm`. Three sources of examples: an sc$^+$-section over ∂X in the sense of Definition 5.4.1 is face-wise sc$^+$ on every $U \subset \partial X$ `Chapter14/BoundaryMultisection · SBLocalization.isFaceScPlusSectionOn_of_isBoundaryScPlusSection`; the zero section is `Chapter14/BoundaryMultisection · SBLocalization.isFaceScPlusSectionOn_fiberZero`; and every sc$^+$-section of W on all of X is face-wise sc$^+$ on every set `Chapter14/HalfSpaceConstSection · SBLocalization.isFaceScPlusSectionOn_of_isScPlusSectionOn_w1` (extra). The last is proved in a tame chart and a tame presentation: the local face germ $O \cap V \cap \{t_i = 0\}$ is a sub-retract of O (Part I's corner retraction), the chart representative of s is sc-smooth on O as a map into F_1, and an sc-smooth map between retracts restricts to a sub-retract of its source. It is what makes the multisection of a constant section an example with boundary (§XIV.26).

Definition 14.1.3 (restated) `Chapter14/BoundaryMultisection · SBLocalization.BoundarySymmetricStructure` `Chapter14/BoundaryMultisection · SBLocalization.IsBoundaryScPlusMultisection`, p. 642. *Statement as formalized*: let V be a neighbourhood of x with the natural action and $U(x) = V \cap \partial X$. A *symmetric sc$^+$-section structure for Λ on $U(x)$* is a finite index set I_x with an action of G_x, and maps s_i^x, $i \in I_x$, with (1) s_i^x face-wise sc$^+$ on $U(x)$; (2) $s^x_{g(i)}(g * y) = \mu(\Gamma(g, y), s_i^x(y))$ for $y \in U(x)$; (3) $\Lambda(w) = |I_x|^{-1} \cdot \#\{i \in I_x : s_i^x(P(w)) = w\}$ for $P(w) \in U(x)$. Each s_i^x is a section over $U(x)$ `Chapter14/BoundaryMultisection · SBLocalization.BoundarySymmetricStructure.P_s`, and a structure restricts to a smaller neighbourhood with the same action `Chapter14/BoundaryMultisection · SBLocalization.BoundarySymmetricStructure.restrict`. $\Lambda : W \to \mathbb{Q}^+$ is a *functor on $W|\partial X$* if $\Lambda(\mu(\varphi, w)) = \Lambda(w)$ for every morphism φ with $s(\varphi) \in \partial X$ and $P(w) = s(\varphi)$ `Chapter14/BoundaryMultisection · SBLocalization.IsBoundaryWFunctor` (then $t(\varphi) \in \partial X$ as well), and an *sc$^+$-multisection over ∂X* if it is such a functor and every $x \in \partial X$ has a good neighbourhood $V(x)$ with a symmetric sc$^+$-section structure on $U(x)$. Only the values of Λ over ∂X enter. *Restated*, in three respects. The text's standing assumption that $|X|$ is paracompact is not part of the definition, which

does not use it. The text indexes the structure by $U(x)$; the formal one is attached to $V(x)$, with $U(x)$ its trace. And the index set I_x is not required to be non-empty; with $I_x = \emptyset$ condition (3) reads $\Lambda(w) = 0^{-1} \cdot 0 = 0$ in $\mathbb{Q}^+$, a reading the text's $|I_x|^{-1}$ does not intend. This last point is a property of the formal definition, discussed with Theorem 14.1.9 (§XIV.7); it is gap G.186 (a) (§XIV.29). *Witness*: for X tame, the zero multisection ($\Lambda(w) = 1$ iff $w = 0_{P(w)}$) is an sc⁺-multisection over ∂X `Chapter14/BoundaryMultisection · SBLocalization.isBoundaryScPlusMultisection_zero`, with one index and the zero section on every $U(x)$ `Chapter14/BoundaryMultisection · SBLocalization.zeroBoundaryStructure`, good neighbourhoods coming from Proposition 14.1.1. A non-degenerate witness, with boundary and non-empty support, is the multisection of a constant section on the half-space bundle (§XIV.26).

Charging the boundary `Chapter14/EmptyIndex · SBLocalization.ChargesBoundary` (extra). Λ *charges* ∂X if over every $x \in \partial X$ there is some w with $\Lambda(w) \neq 0$. For the text's multisections, whose local weights $|I_x|^{-1}\#\{\dots\}$ sum to 1 on every fibre, this holds automatically. For a structure it is the same as non-empty index sets: a structure at a point that Λ charges has $I_x \neq \emptyset$ `Chapter14/EmptyIndex · SBLocalization.BoundarySymmetricStructure.nonempty_I_a6`, since with $I_x = \emptyset$ (3) gives $\Lambda = 0$ over $U(x)$; conversely, with $i \in I_x$ the point $w = s_i^x(x)$ has $\Lambda(w) \geq |I_x|^{-1} > 0$ `Chapter14/EmptyIndex · SBLocalization.chargesBoundary_of_nonempty_a6`. The zero multisection charges ∂X, $\Lambda(0_x) = 1$ `Chapter14/EmptyIndex · SBLocalization.chargesBoundary_zeroMultisection_a6`.

XIV.3 Proposition 14.1.4 (2017: Remark 14.2): the local extension

Proposition 14.1.4 (explicit) `Chapter14/OpenExtension · SBLocalization.proposition_14_1_4_full`, p. 642. *Statement as formalized*: suppose every object lies in a tame strong bundle chart and the object M-polyfold admits sc-smooth partitions of unity. Let $(s_i)_{i \in I_x}$ be a symmetric sc⁺-section structure for some Λ on $U(x) = V(x) \cap \partial X$. Then there are sc⁺-sections $\bar{s}_i$ on $V(x)$ with $\bar{s}_i = s_i$ on $U(x)$ and $\bar{s}_{g(i)}(g * y) = \mu(\Gamma(g, y), \bar{s}_i(y))$ for all $y \in V(x)$ (Definition 13.2.5 (1)). *Explicit*: the two hypotheses are the readings of the text's standing assumptions, "a strong bundle over a tame ep-groupoid" (tame strong bundle charts) and "X admits sc-smooth partitions of unity" (Definition 5.5.1 for the object M-polyfold), the same readings as in Theorem 12.3.9 (Part XII). The paracompactness of $|X|$ and the goodness of $V(x)$ are not used. The text calls the $\bar{s}_i$ "sc⁺-multisections"; sc⁺-sections are meant, as its proof shows. *Witness of the hypotheses*: the trivial bundle $\mathbb{R}^n \times \mathbb{R}^k \to \mathbb{R}^n$ over the trivial ep-groupoid of $\mathbb{R}^n$ `Chapter14/OpenExtension · SBLocalization.proposition_14_1_4_hypotheses_rn`, which has $\partial X = \emptyset$; the half-space bundle of §XIV.26 witnesses them with boundary.

Proof. The text extends each s_i to an sc⁺-section on $V(x)$ "using an sc-smooth partition of unity argument" (Proposition 12.3.7 locally), averages over the stabilizer H of an index, and transports the result along the orbit of the index. The Lean proof has the same two stages, with a different gluing and a different averaging.

Stage 1: the non-equivariant extension. For each i, find an sc⁺-section on $V(x)$ equal to s_i on $V(x) \cap \partial X$ `Chapter14/OpenExtension · SBLocalization.exists_scPlusSectionOn_extension_of_face` (for any open V and any face-wise sc⁺ s on $V \cap \partial X$).

1. *The local step* `Chapter14/LocalExtension · StrongBundle.exists_local_extension_of_face`. Let y lie in a tame strong bundle chart c, let $G \ni y$ be open, and let s be a section with values in $W_{0,1}$ on $G \cap \partial X$ that is sc⁺ on every local face germ at y (for $y \notin \partial X$ there are none). Then there are an open U with $y \in U \subset G$ and an sc⁺-section σ of W with $\sigma = s$ on $U \cap \partial X$. This is Part I's local step of the ∂-extension (Proposition 12.3.7 in a tame chart, Part XII) with the hypothesis made local: the

face condition only at y, the section property only on $G \cap \partial X$. The proof applies the inclusion–exclusion construction at the faces through $\varphi(y)$ `Chapter12/LocalBoundaryExtension · proposition_12_3_7_of_faces_at`, which gives an sc⁺ extension e of the local representative on a neighbourhood V' of $\varphi(y)$; restricts the chart to $S = \mathrm{dom} \cap \varphi^{-1}(V')$; takes an sc-smooth bump function β at y supported in $S \cap G$ `Chapter5/BumpFunctions · proposition_5_5_3`; and sets $\sigma =$ the section cut off by β, $\beta \cdot e$ in the chart and 0 outside, which is sc⁺ `Chapter3/IndexAlongPathsLocalBump · isScPlusSection_cutoffSection_of_isChart` and equals s on the interior of $\{\beta = 1\}$ intersected with $S \cap G \cap \partial X$.

2. *Gluing over a set with closure inside V* `Chapter14/LocalExtension · SBLocalization.exists_scPlusSection_extension_of_face`. Let G be open with $\mathrm{cl}\, G \subset V$. Every object y has a local piece: for $y \in \partial X \cap V$ the local extension of step 1 with $G' = V$; for $y \in \partial X \setminus V$, hence $y \notin \mathrm{cl}\, G$, the zero section on $X \setminus \mathrm{cl}\, G$; for $y \notin \partial X$ the zero section on $X \setminus \partial X$. These open sets cover X; an sc-smooth partition of unity subordinate to them glues the pieces to a global section `Chapter12/ScPlusExtension · glueSection`, which is sc⁺ `Chapter12/ScPlusExtension · isScPlusSection_glueSection`, and at a point of $G \cap \partial X$ every piece whose weight is non-zero there equals s, so the glued section does. A single partition of unity cannot give the extension on all of V: it would have to cover the frontier of V, where the face data may be unbounded and no local extension exists.
3. *Exhaustion.* The object space is metrizable. Let $G_n = \{y : \mathrm{dist}(y, X \setminus V) > 1/(n+1)\}$; then $\mathrm{cl}\, G_n \subset G_{n+1}$ and $\bigcup_n G_n = V$. By step 2, σ_n is a global sc⁺-section equal to s on $G_{n+1} \cap \partial X$.
4. *Cut-offs.* For each n an sc-smooth $\chi_n : X \to [0,1]$ equals 1 on $\mathrm{cl}\, G_n$ and has support in G_{n+1} `Chapter14/OpenExtension · SBLocalization.exists_scSmooth_cutoff_p3w4` (a partition of unity for the two-set cover $\{G_{n+1}, X \setminus \mathrm{cl}\, G_n\}$). With $c_0 = 0$ and $c_{n+1} = \chi_n$, the weights $w_n = c_{n+1} - c_n$ vanish off G_{n+1}, are locally finite on V (on G_m, $c_n = 1$ for $n > m$, so only $w_0, \dots, w_m$ are non-zero there), and sum to 1 on V.
5. *The extension* is $\sum_n w_n \sigma_n$. On each G_m it is a finite sum of sc⁺-sections times sc-smooth functions, hence sc⁺ there; being sc⁺ on an open set is local `Chapter14/OpenExtension · SBLocalization.IsScPlusSectionOn.of_locally_p3w4`, so it is sc⁺ on V. At $y \in V \cap \partial X$, every σ_n with $w_n(y) \neq 0$ has $y \in G_{n+1}$ and so $\sigma_n(y) = s(y)$; the weights sum to 1.

Stage 2: averaging. Given sc⁺-sections σ_k on V (indexed by I_x), the average is `Chapter14/BoundaryMultisection · SBLocalization.avgSection`

$$\bar{s}_j(y) = |G_x|^{-1} \sum_{g \in G_x} \mu\big(\Gamma(g^{-1}, g * y),\ \sigma_{g(j)}(g * y)\big),$$

the sum of the translates `Chapter14/BoundaryMultisection · SBLocalization.avgTerm` taken in the fibre over y. The morphism $\Gamma(g^{-1}, g * y)$ goes from $g * y$ to y `Chapter14/BoundaryMultisection · SBLocalization.src_Γ_inv_Φ` `Chapter14/BoundaryMultisection · SBLocalization.tgt_Γ_inv_Φ`, so each translate is a section over V `Chapter14/BoundaryMultisection · SBLocalization.P_avgTerm`. Each translate is sc⁺ on V `Chapter14/BoundaryMultisection · SBLocalization.isScPlusSectionOn_avgTerm`: $y \mapsto g * y$ is an sc-diffeomorphism of V and $y \mapsto \Gamma(g^{-1}, g*y)$ an sc-smooth family of morphisms, along which the fibre action preserves sc⁺-sections (Part XIII). A finite sum of sc⁺-sections is one `Chapter14/BoundaryMultisection · SBLocalization.isSection_sumSection_p3w3`, so the average is sc⁺ `Chapter14/BoundaryMultisection · SBLocalization.isScPlusSectionOn_avgSection`; its value in the fibre is the displayed sum `Chapter14/BoundaryMultisection · SBLocalization.avgSection_apply`.

1. *The key identity* `Chapter14/BoundaryMultisection · SBLocalization.avgTerm_equivariant`: $\mu(\Gamma(h, y), \mathrm{term}_{gh,j}(y)) = \mathrm{term}_{g,h(j)}(h * y)$. Both sides are μ of a composite morphism applied to $\sigma_{gh(j)}(gh * y)$, and the two composites, $\Gamma(h, y) \circ \Gamma((gh)^{-1}, gh * y)$ and $\Gamma(g^{-1}, g * (h * y))$,

are equal by the multiplicativity of the natural representation; the fibre action is functorial.

2. *Equivariance* `Chapter14/BoundaryMultisection · SBLocalization.avgSection_equivariant`: $\bar{s}_{h(j)}(h * y) = \mu(\Gamma(h,y), \bar{s}_j(y))$. Reindex the sum defining $\bar{s}_j(y)$ along $g \mapsto gh$ and apply the key identity term by term; $\mu(\Gamma(h,y),\cdot)$ is linear on fibres.
3. *The average extends what is already equivariant* `Chapter14/BoundaryMultisection · SBLocalization.avgSection_eq_of_equivariant`: if $\sigma_{g(j)}(g*y) = \mu(\Gamma(g,y),\sigma_j(y))$ on an invariant $B \subset V$, then every translate equals σ_j on B, since $\mu(\Gamma(g^{-1}, g*y)) \circ \mu(\Gamma(g,y)) = \mu(1_y) = \mathrm{id}$, and the average of $|G_x|$ equal terms is that term.
4. *Conclusion* `Chapter14/BoundaryMultisection · SBLocalization.proposition_14_1_4_hyp`: for any sc$^+$-sections σ_i on $V(x)$ with $\sigma_i = s_i$ on $U(x)$, the averages are sc$^+$, equivariant, and equal to s_i on $U(x)$, by 3 with $B = U(x)$, which is invariant (§XIV.1) and on which the s_i are equivariant by Definition 14.1.3 (2). For the zero structure the zero sections are such σ_i `Chapter14/BoundaryMultisection · SBLocalization.proposition_14_1_4_hyp_witness`.

The text averages over the stabilizer of one index of each orbit and transports along the orbit; averaging over all of G_x produces the same symmetry and needs no choice of orbit representatives. Two variants are proved on the way: the extension to any $V' \le V(x)$ with the same action and $\mathrm{cl}\, V' \subset V(x)$, from step 2 alone `Chapter14/LocalExtension · SBLocalization.proposition_14_1_4_of_closure`, and the extension to a good $V'(x) \le V(x)$ with $\mathrm{cl}\, V'(x) \subset V(x)$ provided by Lemma 14.2.1 `Chapter14/LocalExtension · SBLocalization.proposition_14_1_4`.

XIV.4 Definition 14.1.5 and Theorem 14.1.6 (2017: Definition 14.3, Theorem 14.1): good systems for ∂X

Definition 14.1.5 (restated) `Chapter14/BoundaryMultisection · EpGroupoid.BoundaryGoodSystem`, p. 643. A *good system for ∂X* assigns to every $x \in \partial X$ a good neighbourhood $V(x)$ with its natural action (Definition 14.1.2) such that for all $x, x' \in \partial X$ and every connected component Σ of $V(x,x') = \mathcal{U}(V(x), V(x'))$, the maps $s : \Sigma \to V(x)$ and $t : \Sigma \to V(x')$ are sc-diffeomorphisms onto open subsets. It carries $U(x) = V(x) \cap \partial X$ `Chapter14/BoundaryMultisection · EpGroupoid.BoundaryGoodSystem.U` and the boundary morphism sets $\mathcal{U}(x,x') = \mathcal{U}(U(x), U(x'))$ `Chapter14/BoundaryMultisection · EpGroupoid.BoundaryGoodSystem.mor`. *Restated*: the text says that for all x, x' "there exist" good $V(x)$, $V(x')$ restricting to $U(x)$, $U(x')$ with the component condition; one $V(x)$ per point is fixed, which is how the proof of Theorem 14.1.6 chooses them and how every later use takes them. The component condition passes to open subsets `Chapter14/BoundaryMultisection · EpGroupoid.BoundaryGoodSystem.isDiffeoComponent_of_subset`: a component of the smaller morphism set lies in a component of the larger one, on which s and t are sc-diffeomorphisms onto open sets, and their restrictions to an open subset remain so. *Refinement* `Chapter14/BoundaryMultisection · EpGroupoid.BoundaryGoodSystem.exists_refinement`: for tame X and open $W(x) \ni x$, a good system has a refinement inside the $W(x)$ whose neighbourhoods carry the same natural actions; at each x, Proposition 14.1.1 in its relative form (§XIV.1) shrinks $V(x)$ inside $W(x)$ keeping the action, and the component condition passes to the smaller sets. This is the boundary analogue of Proposition 13.1.3.

Theorem 14.1.6 (explicit) `Chapter14/BoundaryMultisection · EpGroupoid.theorem_14_1_6_hyp`, p. 643. *Statement as formalized*: let X be tame with $|X|$ paracompact, and let $O(x) \ni x$ be open in X for $x \in \partial X$. There is a good system for ∂X with $V(x) \subset O(x)$, so $U(x) \subset O(x) \cap \partial X$. A cover of ∂X by sets open in ∂X is written $(O(x) \cap \partial X)$ with $O(x)$ open in X.

Proof, the text's. 1. Put $W(y) = O(y)$ for $y \in \partial X$ and $W(y) = X$ otherwise, and apply Theorem 13.1.8 to X (Part XIII) `Chapter13/GoodSystemExistence · theorem_13_1_8`: there is a good system of X, with neighbourhoods $N(y) \subset W(y)$ carrying the natural action, t proper on $s^{-1}(\mathrm{cl}\, N(y))$, and the component condition. 2. At each $x \in \partial X$, Proposition 14.1.1 in its relative form shrinks $N(x)$ to a good $V(x) \subset N(x)$ with the same action (§XIV.1). 3. The component condition passes from the $N(x)$ to the smaller open $V(x)$, as above. *Explicit*: the text assumes $|\partial X|$ paracompact; its proof applies Theorem 13.1.8 to X, which needs $|X|$ paracompact, and Proposition 14.1.1, which needs X tame. Both are standing assumptions of the chapter, and the formal statement takes them; whether paracompactness of $|\partial X|$ alone suffices is not examined. *Witness*: the trivial ep-groupoid of a tame quadrant `Chapter7/TameBoundaryEp · EpGroupoid.trivial_quadrant_witness`, whose orbit space is paracompact `Chapter7/EpGroupoid · EpGroupoid.hasParacompactOrbitSpace_trivial`, and the half-space ep-groupoid of §XIV.26.

XIV.5 Definition 14.1.7 (2017: Definition 14.4): structured sc⁺-multisections over ∂X

Decorations and correspondences. A *decoration* of Λ `Chapter14/BoundaryStructured · SBLocalization.BoundaryDecoration` is a good system $\mathcal{U}$ for ∂X (Definition 14.1.7 (1)) with a symmetric sc⁺-section structure $S_x = (I_x, (s_i^x))$ for Λ on each $U(x)$ (Definition 14.1.7 (3)). For φ with $s(\varphi) \in U(x)$, $t(\varphi) \in U(x')$ and indices $i \in I_x$, $j \in I_{x'}$, the identity of (4) is $s_j^{x'}(t(\varphi)) = \mu(\varphi, s_i^x(s(\varphi)))$ `Chapter14/BoundaryStructured · SBLocalization.BoundaryDecoration.Compat`. *Correspondences* for a decoration `Chapter14/BoundaryStructured · SBLocalization.BoundaryDecoration.Tau`, p. 645, are maps $\tau_{x,x'} : \mathcal{U}(x,x') \to J(x,x')$, $x, x' \in \partial X$, with (2) $\tau_{x,x'}$ locally constant on $\mathcal{U}(x,x')$ with finitely many values; (a) $\tau_{x',x}(\varphi^{-1}) = \tau_{x,x'}(\varphi)^\sharp$; (b) $\tau_{x,x}(\Gamma(g,z)) = [I_x \xleftarrow{\mathrm{id}} I_x \xrightarrow{g} I_x]$; (c) $\tau_{x,x'}(g' * \varphi * g) = g' * \tau_{x,x'}(\varphi) * g$ for the bi-action of $G_{x'} \times G_x$; and (4) the identity above for every pair (i,j) of $\tau_{x,x'}(\varphi)$. Condition (4) is read pointwise on $\mathcal{U}(x,x')$, as printed; Definition 13.3.4 asks it along the component of φ, and on all of $\mathcal{U}(x,x')$ the two are the same. A *structured tuple* is $(\Lambda, \mathcal{U}, S, \tau)$ `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredTuple` with Λ an sc⁺-multisection functor over ∂X (Definition 14.1.3, whose structures are those of the decoration).

Definition 14.1.7 (restated) `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredMultisection`, p. 644. A *structured sc⁺-multisection over ∂X* is an equivalence class of structured tuples; Λ is *structurable over ∂X* if some class lies over it `Chapter14/BoundaryStructured · SBLocalization.IsBoundaryStructurable`. The text defines the equivalence as "similar to the X-case" (Definition 13.3.8). *The equivalence as formalized* `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredTuple.Equiv`: $T \sim T'$ if $\Lambda = \Lambda'$ over ∂X, and there are open $O(x) \ni x$ with $O(x) \cap \partial X \subset U(x) \cap U'(x)$, $I_x = I'_x$, and $\tau_{x,x'} = \tau'_{x,x'}$, transported along these equalities, on the morphisms from $O(x) \cap \partial X$ to $O(x') \cap \partial X$. It is an equivalence relation `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredTuple.equivalence` `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredTuple.setoid`: transitivity intersects the open sets, which needs no tameness. *Agreement with the literal analogue* `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredTuple.equiv_iff_goodSystem`: for X tame, $T \sim T'$ iff $\Lambda = \Lambda'$ over ∂X and some good system $\mathcal{U}''$ for ∂X with $U''(x) \subset U(x) \cap U'(x)$ carries equal index sets and equal correspondences. One direction takes $O(x) = V''(x)$; the other refines the good system of T inside the $O(x)$ (§XIV.4), whose boundary traces lie in $O(x) \cap \partial X \subset U(x) \cap U'(x)$. The underlying functor of a class `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredMultisection.forget` is well defined over ∂X `Chapter14/BoundaryStructured · SBLocalization.BoundaryStructuredMultisection.forget_mk`, and Λ is structurable iff it

is the functor of a structured tuple Chapter14/BoundaryStructured · SBLocalization.isBoundaryStructurable_iff. *Restated*: as in Definition 14.1.3, the paracompactness of $|X|$ is not part of the definition. *Witness*: for X tame with $|X|$ paracompact, the zero multisection is structurable over ∂X Chapter14/BoundaryStructured · SBLocalization.isBoundaryStructurable_zero, on a good system from Theorem 14.1.6, with the zero structures and $\tau \equiv [\{*\} \leftarrow \{*\} \rightarrow \{*\}]$ Chapter14/BoundaryStructured · SBLocalization.BoundaryDecoration.zeroTau. A non-degenerate witness is the multisection of a constant non-zero section on the half-space bundle (§XIV.26).

XIV.6 Proposition 14.1.8 (2017: Proposition 14.1): generalized strong bundle isomorphisms

Proposition 14.1.8 (stronger), p. 645. *The text*: a generalized strong bundle isomorphism $\bar{f} : W \to W'$ between strong bundles over tame ep-groupoids carries structurable sc⁺-multisections to structurable ones, on the whole bundle and over the boundary; the proof is "similar to" those of Theorems 13.4.1 and 13.4.3, for a representative $W \xleftarrow{\Phi} V \xrightarrow{\Psi} W'$ by strong bundle equivalences with V over a tame ep-groupoid: first pull back along Φ, then push forward along Ψ.

The interior case (same). For sc⁺-multisections of the whole bundle, the push-forward and the pull-back along a generalized strong bundle isomorphism preserve structurability Chapter13/MultisectionPushforward · SBLocalization.GenSBMap.isStructurable_pushMult Chapter13/MultisectionPushforward · SBLocalization.GenSBMap.isStructurable_pullMult; this is Theorems 13.4.1 and 13.4.3 composed along a representative, proved in Part XIII. Nothing in it is specific to the boundary.

The boundary case. For Λ structurable over ∂X (Definition 14.1.7), $\bar{f}_*\Lambda$ is structurable over $\partial X'$, and for Λ' structurable over $\partial X'$, $\bar{f}^*\Lambda'$ is structurable over ∂X: for a representative with tame middle and tame target Chapter14/FacePush · SBLocalization.proposition_14_1_8 Chapter14/FacePush · SBLocalization.proposition_14_1_8_pullMult; for a representative between tame ep-groupoids, the middle being then tame Chapter14/FacePush · SBLocalization.proposition_14_1_8_tame Chapter14/FacePush · SBLocalization.proposition_14_1_8_pullMult_tame; and at the level of classes Chapter14/FacePush · SBLocalization.GenSBMap.proposition_14_1_8 Chapter14/FacePush · SBLocalization.GenSBMap.proposition_14_1_8_pullMult, through the chosen representative of the class (Part X), the pull-back needing only X tame. *Stronger*: the paracompactness of the orbit spaces is not used, and the two steps hold for every pull map (strong bundle equivalences and proper strong bundle coverings) and every strong bundle equivalence.

Proof. The construction is Part XIII's for Theorems 13.4.1 and 13.4.3, carried out over the boundary; what is new is that the transported sections stay sc⁺ on the faces, which the text takes for granted.

1. *Boundaries correspond.* A pull map F is a local sc-diffeomorphism on objects, so it preserves the degeneracy index (Proposition 2.4.4) Chapter14/BoundaryPull · SBLocalization.PullMap.degIndex_obj and $F^{-1}(\partial X') = \partial X$ Chapter14/BoundaryPull · SBLocalization.PullMap.mem_boundary_iff; F restricts to a map of boundary points Chapter14/BoundaryPull · SBLocalization.PullMap.bdryObj. The index is also invariant along morphisms Chapter14/BoundaryPush · SBLocalization.mem_boundary_src_iff_fm, so isomorphic points of W lie over ∂X together Chapter14/BoundaryPush · SBLocalization.mem_boundary_of_π_eq_fm, and Part XIII's transport charts $x \mapsto y$ of an equivalence preserve the boundary Chapter14/BoundaryPush · SBLocalization.transportChart_mem_boundary_iff_fm Chapter14/BoundaryPush · SBLocalization.Q_mem_boundary_iff_fm.
2. *The functors.* A functor over ∂X takes equal values on isomorphic points over ∂X Chapter14/

BoundaryPush · SBLocalization.IsBoundaryWFunctor.eq_of_π_eq_fm. Hence $\Phi^*\Lambda'$ is a functor over ∂X Chapter14/BoundaryPull · SBLocalization.PullMap.isBoundaryWFunctor_pull, and $\Phi_*\Lambda(w') = \Lambda(w)$ whenever w lies over ∂X and $\Phi(w) \cong w'$ Chapter14/BoundaryPush · SBLocalization.pushMult_eq_bdry_fm, so $\Phi_*\Lambda$ is a functor over $\partial X'$ Chapter14/BoundaryPush · SBLocalization.isBoundaryWFunctor_pushMult_fm: Lemma 11.5.2 over the boundary, where only values over ∂X enter.

3. *Pull-back.* For a good system $\mathcal{U}'$ for $\partial X'$, Part XIII's adapted neighbourhoods $N(x)$ (with $F(N(x)) \subset N'(F(x))$ and Φ a local strong bundle isomorphism over $N(x)$) map $U(x)$ into $U'(F(x))$ Chapter14/BoundaryPull · SBLocalization.PullMap.IsPullNbhd.mapsTo_bdry, and the component condition is carried back Chapter14/BoundaryPull · SBLocalization.PullMap.isDiffeoComponent_of_isPull_fm. Shrinking each $N(x)$ to a good neighbourhood with the same action by Proposition 14.1.1 gives a good system for ∂X adapted to $\mathcal{U}'$ Chapter14/BoundaryPull · SBLocalization.PullMap.BdryPullData Chapter14/BoundaryPull · SBLocalization.PullMap.exists_bdryPullData, for X tame. On it, the pulled-back structure has $I_x = I'_{F(x)}$, the action through $F : G_x \to G_{F(x)}$, and sections defined by $\Phi(s_i^x(z)) = s_i'^{F(x)}(F(z))$ Chapter14/BoundaryPull · SBLocalization.PullMap.bdryPullStructure; the decoration Chapter14/BoundaryPull · SBLocalization.PullMap.bdryPullDecoration and correspondences $\tau_{x,y}(\varphi) = \tau'_{F(x),F(y)}(F(\varphi))$ Chapter14/BoundaryPull · SBLocalization.PullMap.bdryPullTau form a structured tuple Chapter14/BoundaryPull · SBLocalization.PullMap.bdryPullTuple; a functor over ∂X with a decoration is an sc⁺-multisection over ∂X Chapter14/BoundaryPull · SBLocalization.BoundaryDecoration.isBoundaryScPlusMultisection_fm. Conditions (2)–(4) and (a)–(c) are Part XIII's arguments; condition (1) of Definition 14.1.3 for the pulled-back sections is the transport property `FacePull_hyp` Chapter14/BoundaryPull · SBLocalization.PullMap.FacePull_hyp: for open O, O' with $F(O) \subset O'$, a section face-wise sc⁺ on $O' \cap \partial X'$ pulls back to one face-wise sc⁺ on $O \cap \partial X$. The pull-back step is proved under this property Chapter14/BoundaryPull · SBLocalization.PullMap.isBoundaryStructurable_pull_hyp, for equivalences in particular Chapter14/BoundaryPull · SBLocalization.proposition_14_1_8_pull_hyp, and the property is a theorem (step 5).
4. *Push-forward.* For an equivalence $F : W \to W'$ with X' tame and a decoration of Λ, Part XIII's push neighbourhoods $N'(y)$ around a transport chart $x_y \mapsto y$ are shrunk to good neighbourhoods with the same action Chapter14/BoundaryPush · SBLocalization.exists_isPushNbhd_bdry_fm; the inverse of the chart maps $U'(y)$ into $U(x_y)$ Chapter14/BoundaryPush · Qinv_mem_bdry_fm, and the component condition is carried forward Chapter14/BoundaryPush · isDiffeoComponent_push_fm. With the chosen point x_y Chapter14/BoundaryPush · SBLocalization.bdryX and neighbourhood Chapter14/BoundaryPush · SBLocalization.bdryPushNbhd this is a good system for $\partial X'$ Chapter14/BoundaryPush · SBLocalization.bdryPushGood. The pushed structure has $I'_y = I_{x_y}$ and sections $s'_i(z) = \mu(\psi_u, \Phi(s_i(u)))$, $u = Q^{-1}(z)$ Chapter14/BoundaryPush · SBLocalization.bdryPushStructure, by Part XIII's pointwise formulas with the section property needed only at the points used Chapter14/BoundaryPush · P_obj_fm Chapter14/BoundaryPush · pushSec_eq_fm Chapter14/BoundaryPush · pushSec_compat_fm; the correspondences are $\tau'_{y,y'}(\varphi') = \tau_{x_y,x_{y'}}(\tilde{\varphi})$ for the lift $\tilde{\varphi}$ of φ', which maps boundary morphisms to boundary morphisms Chapter14/BoundaryPush · liftMor_mem_bdry_fm Chapter14/BoundaryPush · SBLocalization.bdryPushDecoration Chapter14/BoundaryPush · SBLocalization.bdryPushTau. Condition (1) for the pushed sections is the property `FacePush_hyp` Chapter14/BoundaryPush · SBLocalization.FacePush_hyp; the push step is proved under it Chapter14/BoundaryPush · SBLocalization.isBoundaryStructurable_pushMult_hyp, and so is the proposition for a representative Chapter14/BoundaryPush · SBLocalization.proposition_14_1_8_hyp Chapter14/BoundaryPush · SBLocalization.proposition_14_1_8_pullMult_hyp.
5. *The transport of face-wise sc⁺ sections* Chapter14/FaceTransport · SBLocalization.isFaceScPlusSectionOn_of_

localIso, the key lemma. Let $L : W|U \to W'|U'$ be a local strong bundle isomorphism over $\phi : U \to U'$ with fibre map Ψ, $G \subset U$ open around $x \in \partial X$, and $s = \Psi \circ s' \circ \phi$ on $G \cap \partial X$. If s' is face-wise sc$^+$ at $\phi(x)$, then s is at x. *Proof*: given a tame strong bundle chart c of W at x, restrict it to $\operatorname{dom}\varphi \cap G$; the restriction is again a tame chart, and its retract is $O \cap N$ for an open N. Transport the restricted chart along L^{-1}: the result is a tame strong bundle chart of W' with the same model, by Part I's lemma on charts transported along local strong bundle isomorphisms Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.isChart_transportChart Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.isTameChart_transportChart, proved for Theorem 3.6.8. In these two charts the local representatives of s and of s' agree at every point of a local face, since such points are mapped into ∂X, where $s = \Psi \circ s' \circ \phi$. The face condition for s' at $\phi(x)$ in the transported chart is therefore the face condition for s at x in the restricted chart, and a face germ on the smaller retract $O \cap N$ is one on O Chapter14/FaceTransport · IsScPlusOnFaceNear.of_restrict_p6. Since the condition is pointwise Chapter14/FaceTransport · SBLocalization.isFaceScPlusSectionOn_iff_singleton, this proves it on sets.

6. *Both transport properties hold.* `FacePull_hyp` holds for every pull map Chapter14/FaceTransport · SBLocalization.PullMap.facePull_hyp: near every x the pulled-back section is $\Psi \circ s' \circ F$ for the local strong bundle isomorphism of Φ at x, and step 5 applies. `FacePush_hyp` holds for every strong bundle equivalence Chapter14/FacePush · SBLocalization.facePush_hyp_of_equivalence: near $z_0 = Q(u_0)$ the pushed section $z \mapsto \mu(\psi_u, \Phi(s(u)))$ is $\Psi_2 \circ s_1 \circ \phi_2$, where $s_1 = \Phi \circ s \circ F^{-1}$ is s transported along the local strong bundle isomorphism of Φ at u_0, and (ϕ_2, Ψ_2) is the action of the morphisms ψ_u near $\sigma = \psi_{u_0}$, itself a local strong bundle isomorphism with an explicit formula: on an open $\mathcal{T} \ni \sigma$ of morphisms, $\phi_2(t\psi) = s\psi$ and $\Psi_2 = \mu(\psi, \cdot)$ Chapter14/FacePush · SBLocalization.exists_localIso_act_p6 (Part X's local isomorphism of a morphism, with its formula exposed). Step 5 applies twice. Two direct checks of the pull property, superseded by this general one, remain in the formalization: it holds for the identity of every strong bundle Chapter14/BoundaryPull · SBLocalization.PullMap.facePull_hyp_id, and vacuously when $\partial X = \emptyset$ Chapter14/BoundaryPull · SBLocalization.PullMap.facePull_hyp_of_boundary_eq_empty; the push property holds vacuously when $\partial X' = \emptyset$ Chapter14/BoundaryPush · SBLocalization.facePush_hyp_of_boundary_eq_empty.
7. *Assembly.* Pull-backs along every pull map Chapter14/FacePush · SBLocalization.PullMap.isBoundaryStructurable_pull and push-forwards along every equivalence Chapter14/FacePush · SBLocalization.isBoundaryStructurable_pushMult preserve structurability over the boundary; composing them along $W \xleftarrow{\Phi} V \xrightarrow{\Psi} W'$ gives $\bar{f}_* = \Psi_*\Phi^*$ and $\bar{f}^* = \Phi_*\Psi^*$. The middle V is tame when X is Chapter14/FacePush · SBLocalization.SDiagram.isTame_B_p6, because Φ covers an equivalence of ep-groupoids and an ep-groupoid equivalent to a tame one is tame (Part X).

XIV.7 Theorem 14.1.9 and Remark 14.1.10 (2017: Theorem 14.2, Remark 14.3): the ∂-extension theorem

The boundary domain support Chapter14/BoundaryStructured · SBLocalization.boundaryDomSupp: Definition 13.2.14 read over ∂X, the closure of the set of $x \in \partial X$ over which Λ charges a non-zero point, $\Lambda(w) > 0$ for some $w \neq 0_x$. It is saturated Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.isSaturated_boundaryDomSupp, and empty for the zero multisection Chapter14/BoundaryStructured · SBLocalization.boundaryDomSupp_zero.

Theorem 14.1.9 (narrower) Chapter14/BoundaryExtensionTheorem · SBLocalization.theorem_14_1_9_charged_a6 Chap-

ter14/BoundaryExtensionTheorem · SBLocalization.theorem_14_1_9_charged_statement, p. 646. *Statement as formalized*: let $(P : W \to X, \mu)$ be a strong bundle over a tame ep-groupoid X with $|X|$ paracompact, whose object M-polyfold admits sc-smooth partitions of unity, and such that every object lies in a tame strong bundle chart. Let $\Lambda : W|\partial X \to \mathbb{Q}^+$ be structurable over ∂X and charge every boundary fibre, N an auxiliary norm (Definition 8.3.5), $\tilde{U}$ an open saturated set containing the boundary domain support of Λ, and $f : X \to [0, \infty)$ a continuous functor with $\mathrm{cl}\{f \neq 0\} \subset \tilde{U}$ and $N(\Lambda)(x) < f(x)$ on the boundary domain support. Then there is a structurable sc$^+$-multisection functor $\Lambda' : W \to \mathbb{Q}^+$ (Definition 13.3.6) with (1) $N(\Lambda')(x) \leq f(x)$ for all x, (2) dom-supp$(\Lambda') \subset \tilde{U}$, (3) $\Lambda' = \Lambda$ over ∂X. *Narrower*, by the two readings named in the decisions: the tame strong bundle charts at every object, the reading of "a strong bundle over a tame ep-groupoid" used for Proposition 14.1.4 (§XIV.3); and charging, the reading of the factor $|I_x|^{-1}$ of Definition 14.1.3 (3). Both are gap G.186 (§XIV.29). Two readings of the hypotheses on f: "supported in $\tilde{U}$" is read as $\mathrm{cl}\{f \neq 0\} \subset \tilde{U}$; and the text writes $N(\Lambda)(x) < f(x)$ "for $x \in \partial X$" in the theorem, while what is needed and assumed is the inequality on the boundary domain support (off it, $N(\Lambda) = 0$ and $f \geq 0$ would allow $f = 0$). The proof, the whole of §§14.2–14.5, is §XIV.25.

Charging is necessary Chapter14/EmptyIndex · SBLocalization.chargesBoundary_of_structurable_eq_a6: if a structurable Λ' on W agrees with Λ over ∂X, then Λ charges every boundary fibre. *Proof*: a structurable Λ' has local section structures at every point (Definition 13.2.1), whose local weights sum to 1 on every fibre; so over each x some w has $\Lambda'(w) > 0$, and over ∂X this is $\Lambda(w)$. Hence the exact form Chapter14/BoundaryExtensionTheorem · SBLocalization.theorem_14_1_9_iff_a6: under the other hypotheses, a structurable Λ over ∂X has an extension as in the theorem if and only if it charges every boundary fibre. For a structured tuple, charging is the same as non-empty index sets at all boundary points Chapter14/EmptyIndex · SBLocalization.BoundaryStructuredTuple.nonempty_I_a6 (§XIV.2).

Remark: the uncharged Lean statement. The Lean statement of Theorem 14.1.9 without the charging condition and without the tame strong bundle charts Chapter14/BoundaryStructured · SBLocalization.theorem_14_1_9_statement, whose hypotheses are jointly satisfiable ($\Lambda = 0$, $\tilde{U} = \emptyset$, $f = 0$) Chapter14/BoundaryStructured · SBLocalization.theorem_14_1_9_statement_hyp_witness, does not hold when $\partial X \neq \emptyset$ Chapter14/EmptyIndex · SBLocalization.not_theorem_14_1_9_statement_a6, for X tame with $|X|$ paracompact and sc-smooth partitions of unity. Because the formal Definition 14.1.3 admits $I_x = \emptyset$, the function $\Lambda \equiv 0$ is structurable over ∂X in the formal sense Chapter14/EmptyIndex · SBLocalization.isBoundaryStructurable_zeroFun_a6: on a good system from Theorem 14.1.6, with the empty index set at every boundary point Chapter14/EmptyIndex · SBLocalization.emptyBoundaryStructure_a6 under the trivial action on the empty type Chapter14/EmptyIndex · SBLocalization.pemptyAction_a6, and the unique correspondence between empty index sets Chapter14/EmptyIndex · SBLocalization.IndexCorr.eq_of_isEmpty_a6 Chapter14/EmptyIndex · SBLocalization.emptyTau_a6, which satisfies (a)–(c) and (4) vacuously. Its boundary domain support is empty Chapter14/EmptyIndex · SBLocalization.boundaryDomSupp_zeroFun_a6, so $\tilde{U} = \emptyset$ and $f = 0$ satisfy the hypotheses, with N from Theorem 12.2.2; an extension would be structurable and 0 over a boundary point, which necessity excludes. The statement holds when $\partial X = \emptyset$ Chapter14/BoundaryExtensionTheorem · SBLocalization.theorem_14_1_9_statement_of_boundary_eq_empty_a6. This is a property of that Lean statement and of the formal Definition 14.1.3, not of the text, whose $|I_x|^{-1}$ presumes $I_x \neq \emptyset$; the statement with charging above is the one proved. The forms derived from that statement are recorded where they occur (§§XIV.25, XIV.28).

Remark 14.1.10 (2017: Remark 14.3), p. 646, says that the proof needs preparation and is lengthy; nothing to formalize.

XIV.8 Lemmas 14.2.1, 14.2.2 and Proposition 14.2.3 (2017: the text before Lemma 14.1, Lemma 14.1, Proposition 14.2): a good structured representative

§14.2 fixes a representative $(\Lambda, \mathcal{U}^0, S^0, \tau^0)$ of a structured sc⁺-multisection over ∂X; the text names its properties (P1) (the good system), (P2) (the structures) and (P3) (the correspondences), which are the fields of a structured tuple (§XIV.5). It then shrinks the good system so that the level sets of the correspondences acquire disjoint closures, property (P4), which §14.3 needs to separate them by open sets.

Lemma 14.2.1 (same) `Chapter14/GoodStructured · EpGroupoid.lemma_14_2_1`, p. 648. *Statement*: let X be tame, $x \in \partial X$ and $V^0(x)$ a good neighbourhood, $U^0(x) = V^0(x) \cap \partial X$. There is a good neighbourhood $V(x) \le V^0(x)$ (same natural action, restricted) with $\mathrm{cl}_X V(x) \subset V^0(x)$, $\mathrm{cl}_X U(x) \subset U^0(x)$, and $\mathrm{cl}_{|X|} |U(x)| \subset |U^0(x)|$ (14.15). The text states (14.15) with the closure in $|\partial X|$; since $|\partial X| = \pi(\partial X)$ is closed in $|X|$ (§XIV.11), the closure in $|X|$ is the same. The faces, the connectedness and the invariance of $U(x)$ are those of a good neighbourhood (Definition 14.1.2).

Proof. 1. Choose a closed neighbourhood C of x with $C \subset V^0(x)$ (the object space is regular). 2. Apply Proposition 14.1.1 in its relative form inside the interior of C (§XIV.1): this gives a good $V(x) \le V^0(x)$ with $V(x) \subset C$, so $\mathrm{cl}\, V(x) \subset C \subset V^0(x)$, and $\mathrm{cl}\, U(x) \subset \mathrm{cl}\, V(x) \cap \partial X \subset U^0(x)$ because ∂X is closed. 3. For the orbit closure, Proposition 7.1.10 for the proper set $\mathrm{cl}\, V^0(x)$ `Chapter7/Basic · proposition_7_1_10_of_isProperMap` gives $\mathrm{cl}_{|X|}\, \pi(A) = \pi(\mathrm{cl}_X A)$ for $A \subset V^0(x)$ with $\mathrm{cl}\, A$ inside; applied to $A = U(x)$ it gives (14.15). For all boundary points at once `Chapter14/GoodStructured · EpGroupoid.lemma_14_2_1_system`: a good system $\mathcal{U} \le \mathcal{U}^0$ for ∂X with these properties; the component condition passes to the smaller sets (§XIV.4).

Lemma 14.2.2 (same) `Chapter14/GoodStructured · SBLocalization.lemma_14_2_2`, p. 648. *Statement*: let $\mathcal{U}$, $\mathcal{U}^0$ be good systems for ∂X with $\mathrm{cl}_X U(x) \subset U^0(x)$ for all x, and let τ be locally constant on $\mathcal{U}^0(x, x')$. For $[d] \neq [d']$ the closures in the morphism space of $\tau^{-1}([d]) \cap \mathcal{U}(x, x')$ and $\tau^{-1}([d']) \cap \mathcal{U}(x, x')$ are disjoint. *Proof*: $\mathrm{cl}\, \mathcal{U}(x, x') \subset \mathcal{U}^0(x, x')$ `Chapter14/GoodStructured · SBLocalization.closure_mor_subset`, since s and t are continuous and $\mathrm{cl}\, U(x) \subset U^0(x)$. A common limit point φ of the two sets therefore lies in $\mathcal{U}^0(x, x')$, where τ is locally constant; near φ in $\mathcal{U}^0(x, x')$, τ is constant, and the two sets both meet that neighbourhood, so $[d] = \tau(\varphi) = [d']$. *A reading*: the text defines $\mathcal{U}(x, x')$ with $t(\varphi) \in U(x)$; presumably $U(x')$ is meant, as in (P3), and that is what is formalized.

Restriction. A decoration restricts to a smaller good system with the same actions `Chapter14/GoodStructured · SBLocalization.BoundaryDecoration.restrictTo`, the boundary morphism sets shrink `Chapter14/GoodStructured · SBLocalization.BoundaryDecoration.mor_mono`, and the correspondences restrict `Chapter14/GoodStructured · SBLocalization.BoundaryDecoration.Tau.restrict`: local constancy, finiteness of the values, (a)–(c) and (4) are inherited by subsets, and the bi-action is the same because the actions are. The restricted tuple `Chapter14/GoodStructured · SBLocalization.BoundaryStructuredTuple.restrict` is equivalent to the original `Chapter14/GoodStructured · SBLocalization.BoundaryStructuredTuple.equiv_restrict`, with $O(x)$ the smaller neighbourhoods.

Proposition 14.2.3 (same) `Chapter14/GoodStructured · SBLocalization.BoundaryStructuredTuple.proposition_14_2_3`, p. 649. *Statement*: for X tame, every structured tuple $(\Lambda, \mathcal{U}, S, \tau)$ is equivalent to one with the same Λ, the same index sets and the same correspondences on a smaller good system with restricted actions, which has (P4) `Chapter14/GoodStructured · SBLocalization.BoundaryStructuredTuple.HasP4`: for $[d] \neq [d']$ the closures of $\tau^{-1}_{x,x'}([d])$ and $\tau^{-1}_{x,x'}([d'])$ (preimages in $\mathcal{U}(x, x')$) are disjoint. *Proof*: Lemma 14.2.1

for the good system of the tuple, restriction to the smaller system, and Lemma 14.2.2 with $\mathcal{U}^0$ the original system, on which τ is locally constant by (2) of Definition 14.1.7. (P4) persists under further shrinking `Chapter14/GoodStructured · SBLocalization.BoundaryStructuredTuple.HasP4.restrict` (the text: "it will persist when we replace these sets by even smaller ones"), since the preimages only shrink. On classes `Chapter14/GoodStructured · SBLocalization.BoundaryStructuredTuple.proposition_14_2_3_class`: every structured sc⁺-multisection over ∂X of a tame X has a representative with (P4). The hypotheses of Theorem 14.1.9 enter only as tameness.

XIV.9 (P5) and Lemma 14.3.1 (2017: Lemma 14.2): open neighbourhoods of the level sets

(P5) `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds`, p. 649. Fix a tuple with (P1)–(P4). Neighbourhoods $\tilde{U}'(x)$, $x \in \partial X$, with (P5) are open sets of objects with (i) the natural G_x-action and t proper on $s^{-1}(\mathrm{cl}_X \tilde{U}'(x))$, and (ii) $\tilde{U}'(x) \cap \partial X = U^0(x)$. *Reading*: "admits the natural G_x-action" is read as carrying the natural representation of the good system $\mathcal{U}^0$ itself, extended to $\tilde{U}'(x)$; this makes the bi-action on $\tilde{U}'(x,x') = \mathcal{U}(\tilde{U}'(x), \tilde{U}'(x'))$ (14.19) `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.mor` `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.isOpen_mor`, `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.biact`, agree with the bi-action of Definition 14.1.7 (c) on the boundary morphisms `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.biact_eq`, the natural bi-action depending only on the representations `Chapter14/ExtendCorrespondences · EpGroupoid.biact_congr_rep_p3w4`. The bi-action preserves $\tilde{U}'(x,x')$ `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.biact_mem`, and that of $\mathcal{U}^0$ preserves $U^0(x,x')$ `Chapter14/ExtendCorrespondences · EpGroupoid.BoundaryGoodSystem.biact_mem_mor_p3w4`. *Boundary morphisms* are those with source and target in ∂X `Chapter14/ExtendCorrespondences · SBLocalization.boundaryMor`; by (ii), the boundary morphisms of $\tilde{U}'(x,x')$ are exactly $U^0(x,x')$ `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.mor_inter_boundaryMor` `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.mor_subset`, and inversion maps $U^0(x,x')$ to $U^0(x',x)$ `Chapter14/ExtendCorrespondences · EpGroupoid.BoundaryGoodSystem.inv_mem_mor_p3w4`. *Witness*: the open sets $V(x)$ of the good system itself `Chapter14/ExtendCorrespondences · SBLocalization.P5Nbhds.ofGood`, which have $V(x) \cap \partial X = U^0(x)$ by definition.

Two identities of the bi-actions are used: $(g' * [d] * g)^\sharp = g^{-1} * [d]^\sharp * g'^{-1}$ `Chapter14/ExtendCorrespondences · SBLocalization.IndexCorr.swap_biact_p3w4` for correspondences, and $(g' * \varphi * g)^{-1} = g^{-1} * \varphi^{-1} * g'^{-1}$ `Chapter14/ExtendCorrespondences · EpGroupoid.inv_biact_p3w4` for morphisms (Definition 13.1.5).

Lemma 14.3.1 (stronger) `Chapter14/ExtendCorrespondences · SBLocalization.lemma_14_3_1` `Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension`, p. 650. *Statement*: under (P1)–(P5), for all $x, x' \in \partial X$ and every $[d] \in J(x,x')$ there is an open $\tilde{O}_{x,x',[d]} \supset \tau^{0-1}([d])$ with (1) $\tilde{O}_{x,x',[d]} \subset \tilde{U}'(x,x')$; (2) pairwise disjoint closures for $[d] \neq [d']$ `Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.disjoint`, so that a morphism lies in at most one of them `Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.eq_of_mem`; (3) $h * \tilde{O}_{[d]} * g = \tilde{O}_{h*[d]*g}$ `Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.image_biact`; (4) the union $\tilde{O}_{x,x'}$ `Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.Ot` meets ∂X exactly in $U^0(x,x')$ `Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.iUnion_inter_boundaryMor`; and (14.20), $\tilde{O}_{[d]} \cap \partial X = \tau^{0-1}([d])$ `Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.inter_boundaryMor`. *Stronger*: in addition, $\varphi \in \tilde{O}_{x,x',[d]}$ iff $\varphi^{-1} \in \tilde{O}_{x',x,[d]^\sharp}$. The printed form, (1)–(4) alone, is `Chapter14/ExtendCorrespondences · SBLocalization.lemma_14_3_1_book`.

Proof, the text's with one step added.

1. *Separation* Chapter14/ExtendCorrespondences · SBLocalization.CorrPre.exists_of_hasP4 Chapter14/ExtendCorrespondences · SBLocalization.CorrPre. Fix x, x'. The correspondence $\tau^0_{x,x'}$ has finitely many values (Definition 14.1.7 (2)), and by (P4) the closures of its level sets are pairwise disjoint closed sets. The morphism space is metrizable, hence normal, and in a normal space finitely many pairwise disjoint closed sets have open neighbourhoods with pairwise disjoint closures Chapter14/ExtendCorrespondences · P3W4S3.exists_open_disjoint_closure (an induction on the finite set, the empty level sets getting the empty set). Intersecting with the open set $\tilde{U}'(x,x')$ gives open $\tilde{O}'_{x,x',[d]} \supset \tau^{0-1}([d])$ inside $\tilde{U}'(x,x')$ with disjoint closures. The level set lies in $\tilde{U}'(x,x')$ because $U^0(x,x') \subset \tilde{U}'(x,x')$.
2. *Invariance under the bi-action* Chapter14/ExtendCorrespondences · SBLocalization.CorrPre.biInv. Replace $\tilde{O}'_{[d]}$ by $\bigcap_{h,g}(h * \cdot * g)^{-1}(\tilde{O}'_{h*[d]*g})$, the intersection over the finite group $G_{x'} \times G_x$ of the preimages under the bi-action, which is a homeomorphism of $\tilde{U}'(x,x')$. This is the text's $\bigcap h * \tilde{O}'_{[d']} * g$ over the $(h,[d'],g)$ with $h * [d'] * g = [d]$, written through preimages. The result is open, still contains $\tau^{0-1}([d])$ by the equivariance (c) of τ^0 and the invariance of $U^0(x,x')$, keeps (1) and (2) (it is smaller), and satisfies $h * \varphi * g \in \tilde{O}_{h*[d]*g} \iff \varphi \in \tilde{O}_{[d]}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrPre.biInv_biact_mem_iff, which is (3).
3. *Symmetry under inversion* (added) Chapter14/ExtendCorrespondences · SBLocalization.CorrPre.symm. Replace $\tilde{O}_{x,x',[d]}$ by $\tilde{O}_{x,x',[d]} \cap \iota^{-1}(\tilde{O}_{x',x,[d]^\sharp})$, ι the inversion. This is open, contains $\tau^{0-1}([d])$ by (a) of Definition 14.1.7, keeps (1) and (2), and has the symmetry Chapter14/ExtendCorrespondences · SBLocalization.CorrPre.symm_inv_mem_iff, since $[d]^{\sharp\sharp} = [d]$; it keeps (3) Chapter14/ExtendCorrespondences · SBLocalization.CorrPre.symm_biact_mem_iff by the two identities of the bi-actions above.
4. *(4) and (14.20).* A boundary morphism in $\tilde{O}_{[d]}$ lies in $U^0(x,x')$ by (1) and (P5) (ii), so it has some value $\tau^0(\varphi) = [d']$ and lies in $\tilde{O}_{[d']}$; by (2), $[d'] = [d]$. Conversely the level sets are inside.

The inversion symmetry is what makes the extended correspondences satisfy Definition 14.1.7 (a) (§XIV.10), which the z-loops of §14.4 need to be reversible. Only finitely many $[d]$ have non-empty sets.

XIV.10 Definition 14.3.2, Lemma 14.3.3, Proposition 14.3.4 and Remark 14.3.5 (2017: the text before Lemma 14.3, Lemma 14.3, Proposition 14.3, Remark 14.4): the extended correspondences

Definition 14.3.2 (restated) Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.Ohat Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat, p. 651. $\hat{O}_{x,x'}$ is the union of the connected components of $\tilde{O}_{x,x'}$ that meet ∂X. For $\varphi \in \tilde{O}_{x,x'}$, $\hat{\tau}_{x,x'}(\varphi)$ is the unique $[d]$ with $\varphi \in \tilde{O}_{x,x',[d]}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_eq Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.mem_O_tauHat; off $\tilde{O}_{x,x'}$ the value is irrelevant. $\hat{O}_{x,x',[d]} = \{\varphi \in \hat{O}_{x,x'} : \hat{\tau}(\varphi) = [d]\}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.OhatD. *Restated*: the text defines $[d]_\varphi = \tau^0(\psi)$ for a boundary morphism ψ in the component of φ; the formal definition reads the value off the decomposition of Lemma 14.3.1, and the two agree:

1. $\tilde{O}_{x,x'}$ is open Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.isOpen_Ot, lies in $\tilde{U}'(x,x')$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.Ot_subset_mor and contains $U^0(x,x')$

Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.mor_subset_Ot.

2. The $\tilde{O}_{[d]}$ are pairwise disjoint open sets with union $\tilde{O}_{x,x'}$, so the component in the union of a point of one of them lies in it Chapter14/ExtendCorrespondences · P3W4S3.connectedComponentIn_iUnion_subset Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.component_subset: the component is connected and the other sets separate it.
3. Hence $\hat{\tau}$ is constant on the components of $\tilde{O}_{x,x'}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_eq_of_mem_component, and, by (14.20), $\hat{\tau}(\varphi) = \tau^0(\psi)$ for every boundary morphism ψ in the component of φ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_eq_tau_of_mem_component_Ot, which is the text's definition.

(14.23): $\hat{O}_{x,x'} \subset \tilde{O}_{x,x'}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.Ohat_subset_Ot, so $\hat{O}_{x,x'} \subset \tilde{U}'(x,x')$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.Ohat_subset_mor; $U^0(x,x') \subset \hat{O}_{x,x'}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.mor_subset_Ohat, each of its points lying in a component that meets ∂X at that point; and $\hat{O}_{x,x'} \cap \partial X = U^0(x,x')$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.Ohat_inter_boundaryMor by (4). The component in $\tilde{O}_{x,x'}$ of a point of $\hat{O}_{x,x'}$ lies in $\hat{O}_{x,x'}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.component_subset_Ohat, so $\hat{O}_{x,x'}$, a union of components of an open set in a locally connected space, is open Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.isOpen_Ohat. And $\hat{O}_{[d]} = \hat{O} \cap \tilde{O}_{[d]}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.OhatD_eq, with $\hat{O}_{[d]} \cap \partial X = \tau^{0-1}([d])$ (14.24) Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.OhatD_inter_boundaryMor.

Lemma 14.3.3 (same) Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.lemma_14_3_3, p. 651: two boundary morphisms in one component of $\hat{O}_{x,x'}$ have the same τ^0. *Proof*: a component of $\hat{O}_{x,x'}$ lies in a component of $\tilde{O}_{x,x'}$, which lies in one $\tilde{O}_{[d]}$ (item 2 above); by (14.20) both morphisms have $\tau^0 = [d]$. So $\varphi \mapsto [d]_\varphi$ is well defined, and $\hat{\tau}(\varphi) = \tau^0(\psi)$ for every boundary ψ in the component of φ in $\hat{O}_{x,x'}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_eq_tau_of_mem_component. Every component of $\hat{O}_{x,x'}$ contains a boundary morphism, indeed one in the component in $\tilde{O}_{x,x'}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.exists_boundary_mem_component, by definition of $\hat{O}$.

Proposition 14.3.4 (same) Chapter14/ExtendCorrespondences · SBLocalization.proposition_14_3_4, p. 652. *Statement*: under (P1)–(P5) there are open sets $\hat{O}_{x,x'}$ of morphisms with (1) $U^0(x,x') \subset \hat{O}_{x,x'} \subset \tilde{U}'(x,x')$ and $\hat{O}_{x,x'} \cap \partial X = U^0(x,x')$; (2) $\hat{O}_{x,x'}$ invariant under the bi-action of $G_{x'} \times G_x$; (3) a locally constant extension $\hat{\tau}_{x,x'}$ of $\tau^0_{x,x'}$ to $\hat{O}_{x,x'}$, unique among locally constant extensions, with $\hat{\tau}(g' * \varphi * g) = g' * \hat{\tau}(\varphi) * g$ and $\hat{\tau}_{x,x}(\Gamma(g,y)) = \tau^0_{x,x}(\Gamma(g,z))$ for $y \in \tilde{U}'(x)$ with $\Gamma(g,y) \in \hat{O}_{x,x}$ and $z \in U^0(x)$; and the decomposition (14.24). *Proof.*

1. *(1)* is (14.23) above.
2. *Local constancy* Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_locallyConstant: near $\varphi \in \tilde{O}_{[d]}$ the open set $\tilde{O}_{[d]}$ is a neighbourhood on which $\hat{\tau} = [d]$.
3. *Extension* Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_eq_tau: on $U^0(x,x')$, $\varphi \in \tilde{O}_{\tau^0(\varphi)}$ because $\tilde{O}_{[d]} \supset \tau^{0-1}([d])$.
4. *Uniqueness* Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_unique: a function locally constant on $\hat{O}_{x,x'}$ is constant on its components Chapter14/ExtendCorrespondences · P3W4S3.eq_of_mem_connectedComponentIn; every component contains a boundary morphism ψ, where the function equals $\tau^0(\psi) = \hat{\tau}(\psi)$, and $\hat{\tau}$ is constant on the component too. The values of $\hat{\tau}$ on $\hat{O}$ are values of τ^0 Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_image_subset, hence finitely many

Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.finite_tauHat (the text's "taking the same values as τ^0").

5. *Equivariance and (2)* Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_biact: by (3) of Lemma 14.3.1, $\varphi \in \tilde{O}_{[d]}$ iff $h * \varphi * g \in \tilde{O}_{h*[d]*g}$. The bi-action maps $\tilde{O}_{x,x'}$ to itself Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.biact_mem_Ot, and, being a homeomorphism preserving ∂X, maps components meeting ∂X to components meeting ∂X Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.biact_mem_Ohat.
6. *The diagonal property* Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_Γ: $\hat{\tau}_{x,x}(\Gamma(g,y)) = [I_x \xleftarrow{\mathrm{id}} I_x \xrightarrow{g} I_x]$ for $y \in \tilde{U}'(x)$ with $\Gamma(g,y) \in \hat{O}_{x,x}$. The text states it without proof. *Sheets.* For a natural representation on R, every morphism φ between points of R is $\Gamma(g, s(\varphi))$ for exactly one g, its *sheet label* Chapter14/ExtendCorrespondences · EpGroupoid.sheetLabel_p3w4 Chapter14/ExtendCorrespondences · EpGroupoid.Γ_sheetLabel_p3w4 Chapter14/ExtendCorrespondences · EpGroupoid.sheetLabel_eq_p3w4. The sheet $\{\Gamma(g,z)\}$ is open: if $\varphi_0 = \Gamma(g, s(\varphi_0))$, then $\varphi = \Gamma(g, s(\varphi))$ for all φ near φ_0 Chapter14/ExtendCorrespondences · EpGroupoid.eventually_Γ_src_eq_p3w4, because s is a local homeomorphism and $z \mapsto \Gamma(g,z)$ is a continuous local inverse of s through φ_0. So the sheet label is locally constant on the morphisms between points of R Chapter14/ExtendCorrespondences · EpGroupoid.sheetLabel_locallyConstant_p3w4. *The argument.* The component of $\Gamma(g,y)$ in $\tilde{O}_{x,x}$ meets ∂X (as $\Gamma(g,y) \in \hat{O}$), say in ψ; the sheet label is constant on that component, so $\psi = \Gamma(g, s(\psi))$ with $s(\psi) \in U^0(x)$; then $\hat{\tau}(\Gamma(g,y)) = \hat{\tau}(\psi) = \tau^0(\psi) = [\mathrm{id}, g]$ by (b) of Definition 14.1.7.
7. *Inversion* (added): $\varphi \in \hat{O}_{x,x'}$ iff $\varphi^{-1} \in \hat{O}_{x',x}$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.inv_mem_Ohat, inversion being a homeomorphism that preserves ∂X and, by the symmetry of Lemma 14.3.1, maps $\tilde{O}_{x,x'}$ onto $\tilde{O}_{x',x}$; and $\hat{\tau}_{x',x}(\varphi^{-1}) = \hat{\tau}_{x,x'}(\varphi)^\sharp$ Chapter14/ExtendCorrespondences · SBLocalization.CorrExtension.tauHat_inv, which is Definition 14.1.7 (a) for $\hat{\tau}$.

Remark 14.3.5 (2017: Remark 14.4), p. 653, observes that $\hat{O}_{x,x'}$ need not be of the form $\tilde{U}(x,x')$ for neighbourhoods of objects; it states nothing to prove, and nothing formal depends on that form.

XIV.11 Lemmas 14.3.6 and 14.3.7 (2017: Lemmas 14.4, 14.5): a locally finite cover of the boundary

The rest of §14.3 chooses the index set A of the construction and the sets $\hat{V}_a$ on which the local extensions of §14.4 live. Both lemmas are formalized in an abstract setting that the objects of Chapter 14 instantiate (§XIV.12): the boundary is any set B of objects (with $|B|$ closed for Lemma 14.3.6, saturated for Lemma 14.3.7), the neighbourhoods are natural neighbourhoods in the sense of §13.1 (Part XIII), and the sets $\hat{O}_{a,b}$ are any open sets of morphisms that contain the boundary morphisms $U'(a,b)$. The proofs use only these properties; isolating them makes visible which facts of §§14.1–14.3 the lemmas need.

Closed saturated sets. Four small facts about saturated sets are used throughout §§14.3–14.5. A saturated set contains the target of every morphism with source in it Chapter14/BoundaryCover · EpGroupoid.IsSaturated.tgt_mem (that is the definition, read through the inverse morphism); the complement of a saturated set is saturated Chapter14/BoundaryCover · EpGroupoid.isSaturated_compl (a morphism from the complement into the set would, inverted, leave the set); every preimage $\pi^{-1}(S)$ of a set of orbits is saturated Chapter14/BoundaryCover · EpGroupoid.isSaturated_preimage_π; and the saturation of an open set is open Chapter14/BoundaryCover · EpGroupoid.isOpen_saturation, which is Proposition 7.1.8 (Part VII). From these: *a closed saturated set B has closed image $|B|$ in $|X|$* Chapter14/BoundaryCover · EpGroupoid.isClosed_π_image_of_isSaturated.

Proof: the complement of $|B|$ is $\pi(X \setminus B)$, because B is saturated (an orbit meets B iff it lies in B); $X \setminus B$ is open and saturated, so $\pi(X \setminus B)$ is open by Proposition 7.1.8. For $B = \partial X$: the degeneracy index is invariant under morphisms, so ∂X is saturated `Chapter14/CoverVHat · EpGroupoid.isSaturated_boundary_p3w4`, and it is closed; hence $|\partial X|$ is closed in $|X|$, which the text uses tacitly when it treats $|\partial X|$ as a closed subset.

Lemma 14.3.6 (explicit) `Chapter14/BoundaryCover · EpGroupoid.lemma_14_3_6`, p. 654. *Statement*: let $|X|$ be paracompact, B a set of objects with $|B|$ closed in $|X|$, and $\tilde{U}(x)$, for every object x, an open neighbourhood with the natural G_x-action. There are $A \subset B$ and nonempty open sets $\tilde{V}_a \subset \tilde{U}(a)$, $a \in A$, with (1) $|\tilde{V}_a|$ open and $\mathrm{cl}_{|X|}\,|\tilde{V}_a| \subset |\tilde{U}(a)|$, (2) $\tilde{V}_a$ invariant under the natural G_a-action, (3) $(|\tilde{V}_a|)_{a\in A}$ locally finite in $|X|$ and covering $|B|$. *Explicit*: the closedness of $|\partial X|$, which the text's proof uses, is a hypothesis here, discharged for $B = \partial X$ as above.

Proof, the text's.

1. *The cover.* The sets $|\tilde{U}(x)|$, $x \in B$, and $|X| \setminus |B|$ form an open cover of $|X|$, indexed by B plus one extra index: $|\tilde{U}(x)| = \pi(\tilde{U}(x))$ is open by Proposition 7.1.8 (Part VII), and $|X| \setminus |B|$ is open because $|B|$ is closed. It covers: an orbit meeting B at x lies in $|\tilde{U}(x)|$.
2. *Refinement.* $|X|$ is paracompact, so the cover has a locally finite open refinement (v_i) indexed by the same set, each v_i inside the i-th member (precise refinement). A paracompact Hausdorff space is normal, and a point-finite open cover of a normal space can be shrunk to an open cover (w_i) with $\mathrm{cl}\, w_i \subset v_i$; (w_i) is again locally finite.
3. *The sets $\tilde{V}_a$.* For $a \in B$ put $\tilde{V}_a = \tilde{U}(a) \cap \pi^{-1}(w_a)$, and let A be the set of $a \in B$ with $\tilde{V}_a \neq \emptyset$. Then $\tilde{V}_a$ is open, contained in $\tilde{U}(a)$, and invariant under the natural G_a-action, because $\tilde{U}(a)$ is and $\pi^{-1}(w_a)$ is saturated. Its image is $|\tilde{V}_a| = w_a$: $w_a \subset v_a \subset |\tilde{U}(a)|$, so every orbit in w_a meets $\tilde{U}(a)$. So $|\tilde{V}_a|$ is open and $\mathrm{cl}\,|\tilde{V}_a| = \mathrm{cl}\, w_a \subset v_a \subset |\tilde{U}(a)|$.
4. *Local finiteness and cover.* $(|\tilde{V}_a|)_{a\in A}$ is a subfamily of (w_i), re-indexed injectively, hence locally finite. A point $\pi(x)$ with $x \in B$ lies in some w_i; not in the extra one, since $\mathrm{cl}\, w_{\text{extra}} \subset |X| \setminus |B|$; so $\pi(x) \in w_a$ for some $a \in B$, and then $\tilde{V}_a \neq \emptyset$ and $a \in A$.

Lemma 14.3.7 (stronger) `Chapter14/BoundaryCover · EpGroupoid.lemma_14_3_7`, p. 655. *Setting*: B saturated; $a \in A$ fixed; $\tilde{U}'(a)$ a neighbourhood of a with the natural G_a-action; for $b \in A$, $\mathrm{cl}_X\, \tilde{U}(b) \subset \tilde{U}'(b)$ and $\mathrm{cl}_X\, \tilde{U}(b)$ proper (Definition 7.1.13: t is proper on $s^{-1}(\mathrm{cl}_X\, \tilde{U}(b))$); the sets $\hat{O}_{a,b}$ open and containing every φ with $s(\varphi) \in \tilde{U}'(a) \cap B$, $t(\varphi) \in \tilde{U}'(b) \cap B$; and $(|\tilde{V}_b|)_{b\in A}$ locally finite. *Statement*: every $y \in U'(a) = \tilde{U}'(a) \cap B$ has a finite $o(y) \subset A$ and an open $\tilde{O}(y) \ni y$ inside $\tilde{U}'(a)$ with (1) $|\tilde{O}(y)| \cap |\tilde{V}_b| \neq \emptyset$ only for $b \in o(y)$; (2) $g * \tilde{O}(y) = \tilde{O}(g * y)$ and $o(g * y) = o(y)$ for $g \in G_a$; (3) every φ with $s(\varphi) \in \tilde{O}(y)$ and $t(\varphi) \in \tilde{U}(b)$, $b \in o(y)$, lies in $\hat{O}_{a,b}$. *Stronger*: the text asks (3) for $s(\varphi) \in \tilde{O}(y) \cap \tilde{U}(a)$; it holds without the intersection, at no cost.

Proof, the text's, in four steps.

0. *The domain.* $U'(a) = \tilde{U}'(a) \cap B$ is invariant under the natural action: $g * y$ is the target of $\Gamma(g, y)$, whose source y lies in the saturated B.
1. *Finitely many b near each orbit.* By local finiteness every orbit p has an open $W(p) \ni p$ in $|X|$ meeting only finitely many $|\tilde{V}_b|$; let $F(p)$ be that finite set of b. Put $o(y) = F(|y|)$. It depends only on the orbit, so $o(g * y) = o(y)$, which is the second half of (2).
2. *Properness* `Chapter14/BoundaryCover · EpGroupoid.exists_nhds_of_isProperSubset`. For $b \in o(y)$: every morphism φ with $s(\varphi) = y$ and $t(\varphi) \in \mathrm{cl}_X\, \tilde{U}(b)$ lies in $\hat{O}_{a,b}$, because $y \in \tilde{U}'(a) \cap B$, $t(\varphi) \in \mathrm{cl}\, \tilde{U}(b) \subset \tilde{U}'(b)$, and $t(\varphi) \in B$ by saturation `Chapter14/BoundaryCover · EpGroupoid.IsSaturated.tgt_mem`. The gen-

eral lemma: if Q is proper, S open, and every φ with $s(\varphi) = y$, $t(\varphi) \in Q$ lies in S, then the same holds for all φ with $s(\varphi)$ in an open $W \ni y$. Its proof: the inverses of the bad morphisms, $\{\psi \in s^{-1}(Q) : \psi^{-1} \notin S\}$, form a closed subset T of $s^{-1}(Q)$; by properness of t on $s^{-1}(Q)$, $t(T)$ is closed; $y \notin t(T)$ by hypothesis; W is the complement of $t(T)$. So each $b \in o(y)$ gives an open $W_b(y) \ni y$.

3. $O_0(y)$. $O_0(y) = \tilde{U}'(a) \cap \pi^{-1}(W(|y|)) \cap \bigcap_{b \in o(y)} W_b(y)$, a finite intersection of open sets containing y. It has (1), as $|O_0(y)| \subset W(|y|)$, and (3), by step 2 and $\tilde{U}(b) \subset \operatorname{cl} \tilde{U}(b)$.
4. *Symmetrization.* $\tilde{O}(y) = \bigcap_{g \in G_a} \{z \in \tilde{U}'(a) : g * z \in O_0(g * y)\}$. It is open (finite intersection, the actions continuous), contains y (as $g*y \in O_0(g*y)$), lies in $O_0(y)$ (take $g = 1$), so keeps (1) and (3). For (2): $z \in \tilde{O}(y)$ iff $hz \in O_0(hy)$ for all h; then for $g*z$ and $g*y$, $h*(g*z) = (hg)*z \in O_0((hg)*y)$, so $g*\tilde{O}(y) \subset \tilde{O}(g*y)$, and the reverse inclusion is the same argument for g^{-1}, since $g^{-1}*(g*z) = z$ for the natural action.

The G_y-invariance `Chapter14/BoundaryCover · EpGroupoid.lemma_14_3_7_stab`: the text asks $\tilde{O}(y)$ to be G_y-invariant. It is read as invariance under the elements of G_a fixing y, whose natural action near y is that of G_y (every morphism between points of $\tilde{U}'(a)$ is a $\Gamma(g, \cdot)$); by (2), $g * \tilde{O}(y) = \tilde{O}(g * y) = \tilde{O}(y)$ for such g.

The hypotheses of the setting are what the proof uses, named: $\operatorname{cl} \tilde{U}(b) \subset \tilde{U}'(b)$ and its properness come from (P6) (§XIV.12); $\hat{O}_{a,b}$ open with $U'(a,b) \subset \hat{O}_{a,b}$ is Proposition 14.3.4 (1); local finiteness is Lemma 14.3.6 (3); saturation of ∂X is shown above.

XIV.12 (P6) and Proposition 14.3.8 (2017: Proposition 14.4): the sets $\hat{V}_a$

(P6) `Chapter14/CoverVHat · SBLocalization.P5Nbhds.P6Nbhds`, p. 653. Given (P5) neighbourhoods $\tilde{U}'(x)$, $x \in \partial X$, (P6) neighbourhoods are open $\tilde{U}(x) \ni x$ with (i) the natural G_x-action and the properness property, (ii) $\operatorname{cl}_{|X|} |\tilde{U}(x)| \subset |\tilde{U}'(x)|$. *Reading*: "the natural G_x-action" is read as the restriction of that of $\tilde{U}'(x)$, the same representation with $\tilde{U}(x) \subset \tilde{U}'(x)$, so that the bi-actions and the sets $\hat{O}$ of §XIV.10 are the same for both. *The "obvious ramification"* `Chapter14/CoverVHat · SBLocalization.P5Nbhds.P6Nbhds.closure_subset`: $\operatorname{cl}_X \tilde{U}(x) \subset \tilde{U}'(x)$. *Proof*: a point $z \in \operatorname{cl}_X \tilde{U}(x)$ has $|z| \in \operatorname{cl} |\tilde{U}(x)| \subset |\tilde{U}'(x)|$, so z is isomorphic to a point of $\tilde{U}'(x)$; Lemma 13.1.1 (Part XIII), with the properness of $\tilde{U}'(x)$ from (P5) (i), says that a limit of points of $\tilde{U}(x) \subset \tilde{U}'(x)$ isomorphic to points of $\tilde{U}'(x)$ lies in $\tilde{U}'(x)$ itself. *Witness* `Chapter14/CoverVHat · SBLocalization.P5Nbhds.P6Nbhds.exists_`: for any (P5) data, without tameness: choose a closed neighbourhood C of x inside $\tilde{U}'(x)$ and an open neighbourhood with the properness property inside its interior (Proposition 7.1.10 and Corollary 7.1.17, Part VII), intersect over the finite group to make it invariant, and use Proposition 7.1.10 again for (ii).

Off ∂X the neighbourhoods are extended by arbitrary natural neighbourhoods, irrelevant since $A \subset \partial X$; the sets $\hat{O}_{a,b}$ are extended by $\emptyset$ `Chapter14/CoverVHat · SBLocalization.CorrExtension.OhatObj`, so that the abstract lemmas, indexed by objects, apply.

Proposition 14.3.8 (explicit), p. 656. *Abstract form* `Chapter14/CoverVHat · EpGroupoid.proposition_14_3_8`. *Setting*: B saturated; $\tilde{U}'(a)$, $\tilde{U}(a)$ natural neighbourhoods with the same representation, $\operatorname{cl}_X \tilde{U}(b) \subset \tilde{U}'(b)$ proper; $\tilde{V}_a \subset \tilde{U}(a)$ open and invariant, $(|\tilde{V}_a|)$ locally finite and covering $|B|$; $\hat{O}_{a,b}$ open with $U'(a,b) \subset \hat{O}_{a,b}$. *Statement*: the sets (14.32) $\hat{V}_a = (\bigcup_{y \in U'(a)} \tilde{O}(y)) \cap \tilde{V}_a$, with $\tilde{O}(y)$ from Lemma 14.3.7, satisfy (1) $\hat{V}_a$ open, G_a-invariant, $\hat{V}_a \subset \tilde{V}_a \subset \tilde{U}(a)$; (2) $\hat{V}_a \cap B = \tilde{V}_a \cap B$; (3) $(|\hat{V}_a|)$ a locally finite cover of $|B|$ by

open subsets of $|X|$; (4) $\hat{V}_{a,a'} \subset \hat{O}_{a,a'}$, where $\hat{V}_{a,a'}$ is the set of morphisms from $\hat{V}_a$ to $\hat{V}_{a'}$. *Explicit*: the hypotheses are named.

Proof.

1. *(1).* $\hat{V}_a$ is a union of open sets intersected with an open set. Invariance: $g*\tilde{O}(y) = \tilde{O}(g*y)$ (Lemma 14.3.7 (2)) and $g * y \in U'(a)$, so the union is invariant, and $\tilde{V}_a$ is invariant.
2. *(2).* $\tilde{U}(a) \subset \tilde{U}'(a)$ (same representation and (P6)), so a point $y \in \tilde{V}_a \cap B$ lies in $U'(a)$ and in its own $\tilde{O}(y)$; hence $\tilde{V}_a \cap B \subset \hat{V}_a$.
3. *(3).* $|\hat{V}_a|$ is open (Proposition 7.1.8) and contained in $|\tilde{V}_a|$, so the family is locally finite; it covers $|B|$ because $(|\tilde{V}_a|)$ does and, by (2), $\hat{V}_a$ keeps the boundary points of $\tilde{V}_a$.
4. *(4),* the text's argument. Let φ go from $z \in \hat{V}_a$ to $z' \in \hat{V}_{a'}$, and $z \in \tilde{O}(y)$, $y \in U'(a)$. Then $|z| = |z'| \in |\tilde{O}(y)| \cap |\tilde{V}_{a'}|$, so $a' \in o(y)$ by Lemma 14.3.7 (1); and $t(\varphi) = z' \in \tilde{V}_{a'} \subset \tilde{U}(a')$, so $\varphi \in \hat{O}_{a,a'}$ by Lemma 14.3.7 (3). This is where the strengthening of (3) is convenient: $s(\varphi) \in \tilde{O}(y)$ suffices.

Instantiated `Chapter14/CoverVHat · SBLocalization.CorrExtension.proposition_14_3_8`: for a representative with (P1)–(P4), (P5) neighbourhoods, the extension of Lemma 14.3.1, (P6) neighbourhoods, and $|X|$ paracompact, there are $A \subset \partial X$, $\tilde{V}_a$ with the conclusions of Lemma 14.3.6, and $\hat{V}_a$ with (1)–(4) for the $\hat{O}_{a,a'}$ of Definition 14.3.2. Every hypothesis of the abstract form is discharged: saturation of ∂X; closedness of $|\partial X|$; the closure and properness conditions by (P6); $U'(a,b) \subset \hat{O}_{a,b}$ by Proposition 14.3.4 (1). The text's summary (14.33)–(14.38) is contained in this statement.

Definition 14.1.7 (a), (b) for $\hat{\tau}$ on $\hat{V}$. §14.4 needs two properties of $\hat{\tau}$ on the sets $\hat{V}_a$, which Proposition 14.3.4 gives on $\hat{O}$: (b) $\hat{\tau}_{a,a}(\Gamma(g,w)) = [I_a \xleftarrow{\mathrm{id}} I_a \xrightarrow{g} I_a]$ for $w \in \hat{V}_a$ `Chapter14/CoverVHat · SBLocalization.CorrExtension.tauHat_Γ_of_VHat`, since $\Gamma(g,w)$ is a morphism of $\hat{V}_{a,a} \subset \hat{O}_{a,a}$ by (4) and invariance; and (a) $\hat{\tau}_{a',a}(\varphi) = \hat{\tau}_{a,a'}(\varphi^{-1})^\sharp$ on $\hat{V}_{a',a}$ `Chapter14/CoverVHat · SBLocalization.CorrExtension.tauHat_inv_of_VHat`, from step 7 of Proposition 14.3.4. They are the conditions *diag* and *swap* of the setting of §XIV.13.

XIV.13 Remark 14.4.1 and the setting of §14.4 (2017: Remark 14.5, (14.33)–(14.38)): from the objects of §14.3

§14.4 works with the objects of §14.3 through a short list of their properties, (14.33)–(14.38). The formalization does the same: the results of §14.4 are proved in an abstract setting that carries exactly those properties, and the objects of §14.3 are then shown to form an instance of it. **Remark 14.4.1** (2017: Remark 14.5), p. 657, explains the plan of the section (the local extension near ∂X must respect the identifications of indices forced by loops of morphisms) and has nothing to prove.

The combinatorial setting `Chapter14/ZLoops · EpGroupoid.ZSetup`, p. 659: an index set A of objects; for $a \in A$ an open neighbourhood $\tilde{U}(a)$ with the natural G_a-action, a G_a-invariant set $\hat{V}_a \subset \tilde{U}(a)$, and a finite index set I_a with a G_a-action; and maps $\hat{\tau}_{a,a'}$ from morphisms to correspondences $J(a,a')$ with two properties: *diag*, $\hat{\tau}_{a,a}(\Gamma(g,w)) = [I_a \xleftarrow{\mathrm{id}} I_a \xrightarrow{g} I_a]$ for $w \in \hat{V}_{a'}$ and *swap*, $\hat{\tau}_{a',a}(\varphi) = \hat{\tau}_{a,a'}(\varphi^{-1})^\sharp$ for φ from $\hat{V}_{a'}$ to $\hat{V}_a$. These are Definition 14.1.7 (a), (b) for the extended correspondences; the text uses them in the proof of Lemma 14.4.5 without naming them. *Witness* `Chapter14/ZLoops · EpGroupoid.ZSetup.trivialSetup`: every ep-groupoid, with A all objects, $\hat{V}_a = \tilde{U}(a)$ a neighbourhood with the natural action (Theorem 7.1.13, Part VII), one-point index sets and constant $\hat{\tau}$.

The setting with topology Chapter14/ZLoopDeform · EpGroupoid.ZData, pp. 657–664: the combinatorial setting together with the three facts of §14.3 that §14.4 uses: the $\hat{V}_a$ are open (Proposition 14.3.8 (1)); $\mathrm{cl}_X \hat{V}_a \subset \tilde{U}(a)$, which is (14.33); and $\hat{\tau}_{a,a'}$ is locally constant at every morphism from $\hat{V}_a$ to $\hat{V}_{a'}$ (Proposition 14.3.4 through Proposition 14.3.8 (4)). *Witness* Chapter14/ZLoopDeform · EpGroupoid.ZData.trivial: the trivial setting with smaller $\hat{V}_a$, $\mathrm{cl}\,\hat{V}_a \subset \tilde{U}(a)$ (two natural neighbourhoods one inside the other with the same action, by Proposition 7.1.10 and Theorem 7.1.13); in it every a lies in its $\hat{V}_a$ and $i \sim_a i$ Chapter14/ZLoopDeform · EpGroupoid.ZData.trivial_zRel.

The boundary sections Chapter14/ZLoopCoherent · SBLocalization.ZSections, p. 665: over a setting with topology, sections s_i^{0a}, $i \in I_a$, with $P(s_i^{0a}(y)) = y$ and (14.45), $s_{g(i)}^{0a}(g * y) = \mu(\Gamma(g,y), s_i^{0a}(y))$, on $U(a) = \tilde{U}(a) \cap \partial X$, and Definition 14.1.7 (4) for $\hat{\tau}$: $s_j^{0a'}(t(\varphi)) = \mu(\varphi, s_i^{0a}(s(\varphi)))$ whenever (i,j) is a pair of $\hat{\tau}_{a,a'}(\varphi)$ and φ is a morphism from $\hat{V}_a$ to $\hat{V}_{a'}$ with source in ∂X (there $\hat{\tau} = \tau^0$). A morphism has source in ∂X iff its target is Chapter14/ZLoopCoherent · SBLocalization.tgt_mem_boundary_iff_z4, so such a φ is a boundary morphism. *Witness* Chapter14/ZLoopCoherent · SBLocalization.ZSections.zero: the zero sections over the trivial setting.

The objects of §14.3 (explicit) Chapter14/ZLoopSetting · SBLocalization.ZConcrete: for a tuple T with (P4), (P5) neighbourhoods, an extension E of the correspondences (Lemma 14.3.1) and (P6) neighbourhoods, the data of Proposition 14.3.8: the set $A \subset \partial X$, the sets $\tilde{V}_a$ with the conclusions of Lemma 14.3.6, the sets $\hat{V}_a$ with (1)–(4) of Proposition 14.3.8, and a base point $x_0 \in \partial X$ that fixes irrelevant values off ∂X. They exist when $|X|$ is paracompact and $\partial X \neq \emptyset$ Chapter14/ZLoopSetting · SBLocalization.ZConcrete.exists_, by the instantiated Proposition 14.3.8 (§XIV.12); the whole chain from (P4) Chapter14/ZLoopSetting · SBLocalization.exists_zConcrete_of_hasP4: (P5) from the good system of T (§XIV.9), the extension from Lemma 14.3.1, (P6) from its witness, and the data from Proposition 14.3.8; and for tame X with $|X|$ paracompact and a boundary point, from the zero tuple with (P4) by Proposition 14.2.3 Chapter14/ZLoopSetting · SBLocalization.exists_zConcrete_of_tame, a nonvacuity check.

Index transport. The objects of §14.3 are indexed by boundary points (a subtype of the objects), those of §14.4 by objects. A retraction r of the objects onto ∂X, the identity on ∂X and x_0 elsewhere Chapter14/ZLoopSetting · SBLocalization.bdryRetr_z5 Chapter14/ZLoopSetting · SBLocalization.bdryRetr_z5_of_mem, with the homomorphism $G_a \to G_{r(a)}$ that is the identity on morphisms for $a \in \partial X$ Chapter14/ZLoopSetting · SBLocalization.isoRetr_z5, carries the index sets, actions and correspondences over without casts; the natural action at $r(a)$ through this homomorphism is that at a, and $[\mathrm{id}, g]$ is unchanged by the relabelling. The base point only fixes values at objects off ∂X, where no $a \in A$ lies.

The instance. Chapter14/ZLoopSetting · SBLocalization.ZConcrete.toZData: $\tilde{U}(a)$ the (P6) neighbourhood, $\hat{V}_a$ from Proposition 14.3.8, I_a the index set of T at a, and $\hat{\tau}_{a,a'}$ the extended correspondence of Definition 14.3.2. Every field is a proved property: *diag* and *swap* are the last two properties of §XIV.12; $\hat{V}_a$ open and invariant is Proposition 14.3.8 (1); local constancy of $\hat{\tau}$ at the morphisms of $\hat{V}_{a,a'}$ is Proposition 14.3.4 with $\hat{V}_{a,a'} \subset \hat{O}_{a,a'}$; and $\mathrm{cl}_X \hat{V}_a \subset \tilde{U}(a)$ Chapter14/ZLoopSetting · SBLocalization.ZConcrete.closure_Vh_subset comes from $\mathrm{cl}_{|X|} |\tilde{V}_a| \subset |\tilde{U}(a)|$ (Lemma 14.3.6 (1)), Lemma 13.1.1 (Part XIII) and the properness of $\tilde{U}(a)$, exactly as the text derives (14.33). *The boundary sections* Chapter14/ZLoopSetting · SBLocalization.ZConcrete.toZSections are those of T: (14.45) is Definition 14.1.3 (2); Definition 14.1.7 (4) for $\hat{\tau}$ along the boundary morphisms Chapter14/ZLoopSetting · SBLocalization.ZConcrete.compatNbhd holds because $\hat{\tau} = \tau^0$ on the boundary morphisms (Proposition 14.3.4 (3)) and $\tilde{U}(a) \cap \partial X \subset U^0(a)$, where the tuple's sections live. A pair of a correspondence satisfies every condition the correspondence satisfies, which is how Definition 14.1.7 (4), stated for all representatives, applies to a pair. *The facts used by the limit ar-*

gument (§XIV.16) `Chapter14/ZLoopSetting · SBLocalization.ZConcrete.toLimit`: the sets $\widehat{O}_{b,c}$, which contain the boundary morphisms from $\tilde{U}(b)$ to $\mathrm{cl}_X \tilde{U}(c)$ `Chapter14/ZLoopSetting · SBLocalization.ZConcrete.morBetween_subset_Ohat` (since $\mathrm{cl}\,\tilde{U}(c) \subset \tilde{U}'(c)$ by (P6) and $U'(b,c) \subset \widehat{O}_{b,c}$); the properness of $\mathrm{cl}_X \tilde{U}(b)$ `Chapter14/ZLoopSetting · SBLocalization.ZConcrete.isProper`; and the local finiteness of Proposition 14.3.8 (3).

Verdict: explicit. The setting is the text's; the identification of objects with boundary points and the three facts are named.

XIV.14 Definitions 14.4.2–14.4.4 and Lemma 14.4.5 (2017: Definitions 14.5–14.7, Lemma 14.6): z-loops and the relations $\sim_z$

Pairs of a correspondence `Chapter14/ZLoops · SBLocalization.IndexCorr.Pairs`: for a correspondence $\tau = [I \xleftarrow{\alpha} K \xrightarrow{\beta} I']$, (i,j) is a pair if $(i,j) = (\alpha(k), \beta(k))$ for some k; this does not depend on the representative, since equivalent representatives differ by a bijection of K. The pairs of $\tau^\sharp$ are the reversed pairs of τ `Chapter14/ZLoops · SBLocalization.IndexCorr.pairs_swap`, and the pairs of $[\mathrm{id}, g]$ are the $(i, g(i))$ `Chapter14/ZLoops · SBLocalization.IndexCorr.pairs_ofPerm`.

Definitions 14.4.2 and 14.4.3 (restated) `Chapter14/ZLoops · EpGroupoid.ZSetup.Arc`, pp. 659–660. The text: for $a \in A$ and $z \in \widehat{V}_a$, a z-loop is a sequence $a = a_0, \dots, a_n = a$ in A with composable morphisms φ_j from $\widehat{V}_{a_j}$ to $\widehat{V}_{a_{j+1}}$, $s(\varphi_0) = z$, composing to 1_z; a z-arc along it is a sequence of indices $i_j \in I_{a_j}$ with each (i_j, i_{j+1}) of the form $(\alpha_j(k_j), \beta_j(k_j))$ for a representative of $\hat{\tau}_{a_j, a_{j+1}}(\varphi_j)$. *As formalized*, loop and arc are one inductive predicate $\mathrm{Arc}(a, b, i, j, \varphi)$: "there are $a = a_0, \dots, a_m = b$ in A, composable morphisms through the $\widehat{V}_{a_j}$ with composite φ, and indices $i = i_0, \dots, i_m = j$ with (i_j, i_{j+1}) a pair of $\hat{\tau}_{a_j, a_{j+1}}(\varphi_j)$". It is generated by two rules: *start*, $\mathrm{Arc}(a, a, i, i, 1_z)$ for $a \in A$, $z \in \widehat{V}_a$; and *append*, from $\mathrm{Arc}(a, b, i, j, \varphi)$, a morphism ψ with $s(\psi) = t(\varphi)$, $t(\psi) \in \widehat{V}_c$, $c \in A$, and a pair (j,k) of $\hat{\tau}_{b,c}(\psi)$, conclude $\mathrm{Arc}(a, c, i, k, \psi \circ \varphi)$. A z-loop with a z-arc from i to i' is $\mathrm{Arc}(a, a, i, i', 1_z)$: the composite 1_z fixes the start and the end at z. Every arc has $a, b \in A$, $s(\varphi) \in \widehat{V}_a$ and $t(\varphi) \in \widehat{V}_b$, by induction. *Restated*: the text's loop is a sequence and the arc a further sequence along it; the predicate records only what the later proofs use, the composite and the end indices.

Concatenation `Chapter14/ZLoops · EpGroupoid.ZSetup.Arc.trans`: from $\mathrm{Arc}(a, b, i, j, \varphi)$ and $\mathrm{Arc}(b, c, j, k, \psi)$ with $s(\psi) = t(\varphi)$, $\mathrm{Arc}(a, c, i, k, \psi \circ \varphi)$. *Proof*: induction on the second arc; its start $1_{t(\varphi)}$ composes to φ, and each appended step is appended to the concatenation, by associativity. *Reversal* `Chapter14/ZLoops · EpGroupoid.ZSetup.Arc.symm`: from $\mathrm{Arc}(a, b, i, j, \varphi)$, $\mathrm{Arc}(b, a, j, i, \varphi^{-1})$. *Proof*: induction; for an appended step ψ with pair (j,k) of $\hat{\tau}_{b,c}(\psi)$, the reversed chain starts with ψ^{-1} from $\widehat{V}_c$ to $\widehat{V}_b$, whose correspondence is $\hat{\tau}_{c,b}(\psi^{-1}) = \hat{\tau}_{b,c}(\psi)^\sharp$ by *swap*, with the reversed pair (k,j); it is followed by the reversal of the rest, and $(\psi \circ \varphi)^{-1} = \varphi^{-1} \circ \psi^{-1}$.

Definition 14.4.4 (same) `Chapter14/ZLoops · EpGroupoid.ZSetup.ZRel`, p. 660: $i \sim_z i'$ if there is a z-loop for a with a z-arc from i to i', that is, $\mathrm{Arc}(a, a, i, i', 1_z)$; the class (14.43) is $[i]_{\sim_z} = \{i' : i' \sim_z i\}$ `Chapter14/ZLoops · EpGroupoid.ZSetup.zClass`. $i \sim_z i'$ forces $z \in \widehat{V}_a$ `Chapter14/ZLoops · EpGroupoid.ZSetup.ZRel.mem_V`. *$\sim_z$ is an equivalence relation* `Chapter14/ZLoops · EpGroupoid.ZSetup.zRel_equivalence` for $a \in A$, $z \in \widehat{V}_a$, as the text calls it without proof: reflexivity is the start rule; symmetry is reversal, $1_z^{-1} = 1_z$; transitivity is concatenation, $1_z \circ 1_z = 1_z$.

Loops of length zero. The start rule gives loops with no morphism, which the text does not list. They

add nothing `Chapter14/ZLoops · EpGroupoid.ZSetup.zRel_iff_unit_step`: $i \sim_z i'$ iff a loop with at least one step relates them. *Proof*: append the step $1_z = \Gamma(1, z)$ from $\hat{V}_a$ to $\hat{V}_a$, whose correspondence is $[\mathrm{id}, 1] = [\mathrm{id}]$ by *diag*, with pairs (i', i'); conversely a loop with a last step is a loop.

Lemma 14.4.5 (explicit) `Chapter14/ZLoops · EpGroupoid.ZSetup.lemma_14_4_5`, p. 660. *Statement*: for $a \in A$, $z \in \hat{V}_a$, $i, i' \in I_a$ and $g \in G_a$, $i \sim_z i'$ iff $g(i) \sim_{g*z} g(i')$; hence $[g(i)]_{\sim_{g*z}} = g([i]_{\sim_z})$ `Chapter14/ZLoops · EpGroupoid.ZSetup.lemma_14_4_5_class`. *Explicit*: *diag* is a hypothesis of the setting. *Proof*, the text's `Chapter14/ZLoops · EpGroupoid.ZSetup.zRel_smul`. Let $w = g * z$, which lies in $\hat{V}_a$ by invariance.

1. *The first step.* $\Gamma(g^{-1}, w)$ is a morphism from w to $g^{-1} * w = z$, between points of $\hat{V}_a$, with correspondence $[\mathrm{id}, g^{-1}]$ by *diag*; its pairs are $(k, g^{-1}(k))$, so $(g(i), i)$ is one. Start at w with index $g(i)$ and append this step: $\mathrm{Arc}(a, a, g(i), i, \Gamma(g^{-1}, w))$.
2. *The loop.* Concatenate the given $\mathrm{Arc}(a, a, i, i', 1_z)$: the composite is $\Gamma(g^{-1}, w)$ again.
3. *The last step.* Append $\Gamma(g, z)$ from z to w, correspondence $[\mathrm{id}, g]$, pair $(i', g(i'))$. The composite is $\Gamma(g, z) \circ \Gamma(g^{-1}, w) = 1_w$, by the functoriality of the natural representation ($\Gamma(g, g^{-1} * w) \circ \Gamma(g^{-1}, w) = \Gamma(gg^{-1}, w)$). So $g(i) \sim_w g(i')$.
4. *The converse* applies this to g^{-1} and w: $g^{-1}(g(i)) = i$, $g^{-1} * w = z$. The class identity follows from the equivalence at each i'.

XIV.15 Proposition 14.4.6 (1) and Lemma 14.4.7 (2017: Proposition 14.5 (1), Lemma 14.7): deforming z-loops

Proposition 14.4.6 (1) (same) `Chapter14/ZLoopDeform · EpGroupoid.ZData.proposition_14_4_6_1`, p. 661. *Statement*: if $i \sim_{z_0} i'$, then $i \sim_z i'$ for all z near z_0 (all of them in $\hat{V}_a$). Open-set form `Chapter14/ZLoopDeform · EpGroupoid.ZData.proposition_14_4_6_1_open`: an open $O \ni z_0$, $O \subset \hat{V}_a$, with $i \sim_z i'$ on O. Class form `Chapter14/ZLoopDeform · EpGroupoid.ZData.eventually_zClass_subset`: $[i]_{\sim_{z_0}} \subset [i]_{\sim_z}$ for z near z_0, because I_a is finite and finitely many "eventually" statements hold together.

The text's proof moves the morphisms of a z_0-loop along with z, using the finite natural representation of Lemma 14.4.7, and concludes by the local constancy of $\hat{\tau}$. *The Lean proof* moves them along sheets (Definition 7.1.4, Part VII), the open sets of morphisms on which s is an sc-diffeomorphism onto an open set, and does not need Lemma 14.4.7.

Sheets. For a sheet $\mathbf{U}$, the local inverse $(s|\mathbf{U})^{-1}$ is defined on the open set $s(\mathbf{U})$ and continuous; $\mathbf{U}$ is open; $(s|\mathbf{U})^{-1}(s(\varphi)) = \varphi$ for $\varphi \in \mathbf{U}$; and $(s|\mathbf{U})^{-1}(z) \to \varphi$ as $z \to s(\varphi)$ `Chapter14/ZLoopDeform · EpGroupoid.Sheet.tendsto_srcInv`. If $1_x \in \mathbf{U}$, then $(s|\mathbf{U})^{-1}(z) = 1_z$ for z near x `Chapter14/ZLoopDeform · EpGroupoid.Sheet.eventually_srcInv_eq_unit`: the unit map is continuous, so $1_z \in \mathbf{U}$ for z near x, and 1_z has source z, where $s|\mathbf{U}$ is injective. Composition is continuous along composable pairs `Chapter14/ZLoopDeform · EpGroupoid.tendsto_comp_of_eventually`: if $a_n \to a_0$, $b_n \to b_0$ and a_n, b_n are eventually composable, then $a_n \circ b_n \to a_0 \circ b_0$, since the multiplication is continuous on the fibre product, which carries the subspace topology.

Key step `Chapter14/ZLoopDeform · EpGroupoid.ZData.Arc.eventually_srcInv`: if $\mathrm{Arc}(a, b, i, j, \varphi)$ and $\mathbf{U} \ni \varphi$ is a sheet, then $\mathrm{Arc}(a, b, i, j, (s|\mathbf{U})^{-1}(z))$ for all z near $s(\varphi)$. *Proof*, by induction on the arc.

1. *Start*: $\varphi = 1_{z_0}$, $z_0 \in \hat{V}_a$. For z near z_0, $(s|\mathbf{U})^{-1}(z) = 1_z$ and $z \in \hat{V}_a$ ($\hat{V}_a$ open), so the start rule applies at z.
2. *Append*: $\varphi = \psi \circ \varphi_1$ with $\mathrm{Arc}(a, b', i, j', \varphi_1)$, $s(\psi) = t(\varphi_1)$, $t(\psi) \in \hat{V}_b$, (j', j) a pair of $\hat{\tau}_{b',b}(\psi)$. Choose sheets $\mathbf{U}_1 \ni \varphi_1$ and $\mathbf{U}_2 \ni \psi$ (sheets cover the morphisms, s being a local sc-

diffeomorphism). For z near $s(\varphi_1) = s(\varphi)$: $\varphi_1' = (s|\mathbf{U}_1)^{-1}(z)$ carries an arc from i to j', by induction, and is near φ_1; so $t(\varphi_1')$ is near $s(\psi)$ and $\psi' = (s|\mathbf{U}_2)^{-1}(t(\varphi_1'))$ is defined and near ψ.

3. *The step survives*: $t(\psi') \in \widehat{V}_b$ for ψ' near ψ ($\widehat{V}_b$ open, t continuous); ψ is a morphism from $\widehat{V}_{b'}$ to $\widehat{V}_b$ (its source is $t(\varphi_1) \in \widehat{V}_{b'}$), where $\widehat{\tau}_{b',b}$ is locally constant, so $\widehat{\tau}_{b',b}(\psi') = \widehat{\tau}_{b',b}(\psi)$ and (j', j) is still a pair. Hence $\mathrm{Arc}(a, b, i, j, \psi' \circ \varphi_1')$.
4. *Identification*: $\psi' \circ \varphi_1' \to \psi \circ \varphi_1 = \varphi$ by continuity of composition, so it eventually lies in the open sheet $\mathbf{U}$; it has source z, so it equals $(s|\mathbf{U})^{-1}(z)$.

Proof of (1). $i \sim_{z_0} i'$ is $\mathrm{Arc}(a, a, i, i', 1_{z_0})$. Take a sheet $\mathbf{U} \ni 1_{z_0}$: by the key step, $\mathrm{Arc}(a, a, i, i', (s|\mathbf{U})^{-1}(z))$ for z near z_0, and $(s|\mathbf{U})^{-1}(z) = 1_z$ for z near z_0. So $i \sim_z i'$.

Lemma 14.4.7 (restated) `Chapter14/FiniteRepresentation · EpGroupoid.lemma_14_4_7`, pp. 661–662. The text restates Proposition 7.1.15 and Corollary 7.1.17 (Part VII) for a finite set Y of isomorphic objects and open $Q(x) \ni x$. Part VII has the proposition as a structure (a natural representation of Y inside one open set): open, connected, mutually disjoint $O(x)$, $x \in Y$, a functor f from the morphisms between points of Y to sc-diffeomorphisms $f(\psi) : O(s(\psi)) \to O(t(\psi))$, the morphisms between points of $O = \bigcup O(x)$ the disjoint union of components $\mathbf{O}(\psi)$, and items (1)–(3). The lemma adds:

1. *Per-object neighbourhoods and (7)* `Chapter14/FiniteRepresentation · EpGroupoid.exists_naturalRepFinite_subset`: $O(x) \subset Q(x)$, and each $\mathrm{cl}\, O(x)$ proper. *Proof*: choose pairwise disjoint open neighbourhoods of the finitely many points of Y inside the $Q(x)$ with the properness property (Hausdorff, Corollary 7.1.17), apply Proposition 7.1.15 inside their union, and note that the connected $O(x) \ni x$ lies in the member containing x.
2. *(4)* `Chapter14/FiniteRepresentation · EpGroupoid.NaturalRepFinite.F_isotropy`: for $g \in G_x$, $f(g)(z) = t(\Gamma(g, z)) = g * z$, with a natural representation of G_x on $O(x)$: the restriction of the representation to the isotropy group is one.
3. *(5)* `Chapter14/FiniteRepresentation · EpGroupoid.NaturalRepFinite.F_equivariant`: $f(\varphi)(g * z) = \gamma_\varphi(g) * f(\varphi)(z)$ with $\gamma_\varphi(g) = \varphi \circ g \circ \varphi^{-1}$: functoriality, $f(\varphi) \circ f(g) = f(\varphi g) = f(\gamma_\varphi(g)\varphi) = f(\gamma_\varphi(g)) \circ f(\varphi)$.
4. *(6)*: the multiplication $\mathbf{O}(\psi) \times_{s,t} \mathbf{O}(\varphi) \to \mathbf{O}(\psi \circ \varphi)$. *The key identity* `Chapter14/FiniteRepresentation · EpGroupoid.NaturalRepFinite.comp_srcInv_eq`: for $\varphi' \in \mathbf{O}(\varphi)$, $(s|\mathbf{O}(\psi))^{-1}(t(\varphi')) \circ \varphi' = (s|\mathbf{O}(\psi \circ \varphi))^{-1}(s(\varphi'))$. *Proof* by connectedness: the map $\varphi' \mapsto (s|\mathbf{O}(\psi))^{-1}(t(\varphi')) \circ \varphi'$ is continuous on the connected $\mathbf{O}(\varphi)$ and takes φ to $\psi \circ \varphi$; its image is connected and consists of morphisms between points of O, so it lies in one component, $\mathbf{O}(\psi \circ \varphi)$; there s is injective. *Bijection* `Chapter14/FiniteRepresentation · EpGroupoid.NaturalRepFinite.bijOn_comp`: every pair (ψ', φ') of the fibre product has $\psi' = (s|\mathbf{O}(\psi))^{-1}(t(\varphi'))$, so $m(\psi', \varphi') = (s|\mathbf{O}(\psi \circ \varphi))^{-1}(s(\varphi'))$, injective in φ'; surjectivity uses the inverse $\chi \mapsto (\ldots, (s|\mathbf{O}(\varphi))^{-1}(s(\chi)))$. *sc-diffeomorphism* `Chapter14/FiniteRepresentation · EpGroupoid.NaturalRepFinite.isScDiffeoOn_comp`: parametrizing the fibre product by its second factor, the multiplication is $(s|\mathbf{O}(\psi \circ \varphi))^{-1} \circ s : \mathbf{O}(\varphi) \to \mathbf{O}(\psi \circ \varphi)$, with inverse $(s|\mathbf{O}(\varphi))^{-1} \circ s$, both composites of sc-diffeomorphisms. *Restated*: the text's fibre product is an M-polyfold; the parametrization by the second factor avoids building that structure.

Lemma 14.4.7 is not used by the proof of Proposition 14.4.6 (1) above; it is used by the proof of (2) (§XIV.16).

XIV.16 Proposition 14.4.6 (2) (2017: Proposition 14.5 (2)): limits of z-loops

Transport along chains. Over boundary sections (§XIV.13), the sections are transported along every arc that starts in ∂X `Chapter14/ZLoopCoherent · SBLocalization.ZSections.arc_transport`: from $\mathrm{Arc}(a,b,i,j,\varphi)$ with $s(\varphi)\in\partial X$, $s_j^{0b}(t(\varphi))=\mu(\varphi,s_i^{0a}(s(\varphi)))$. *Proof* by induction: at the start $\mu(1_z,w)=w$; for an appended ψ with pair (j',j) of $\hat\tau(\psi)$, the source $t(\varphi_1)$ of ψ is in ∂X by saturation, so Definition 14.1.7 (4) for $\hat\tau$ gives $s_j(t\psi)=\mu(\psi,s_{j'}(s\psi))$, and $\mu(\psi,\mu(\varphi_1,\cdot))=\mu(\psi\circ\varphi_1,\cdot)$ (Definition 8.3.5, Part VIII). For a loop, $\varphi=1_z$: if $i\sim_z i'$ with $z\in V_a=\hat V_a\cap\partial X$, then $s_{i'}^{0a}(z)=s_i^{0a}(z)$ `Chapter14/ZLoopCoherent · SBLocalization.ZSections.zRel_sections_eq`.

Proposition 14.4.6 (2) at points of V_a `Chapter14/ZLoopCoherent · SBLocalization.ZSections.proposition_14_4_6_2_of_mem`: if $z_0\in V_a$ and $i\sim_{z_0} i'$, then $s_i^{0a}=s_{i'}^{0a}$ on a neighbourhood of z_0 in ∂X. *Proof*: by (1), $i\sim_z i'$ for z near z_0, and at those z in ∂X the transport gives the equality.

Proposition 14.4.6 (2) (same, and stronger), p. 661. *The printed form* `Chapter14/ZLoopCoherent · SBLocalization.proposition_14_4_6_2_statement`: if $z_k\in V_a$, $i\sim_{z_k} i'$ and $z_k\to z_0\in \mathrm{cl}_X(V_a)$, then $s_i^{0a}=s_{i'}^{0a}$ on a neighbourhood of z_0 in $U(a)$. The sequences are read as closure: $z_0\in\mathrm{cl}\{y\in V_a : i\sim_y i'\}$. *The form with $z_k\in\hat V_a$* `Chapter14/ZLoopCoherent · SBLocalization.HasThetaLocalEq`: for $(i,i')\in\Theta_{z_0}$ (Definition 14.4.8, §XIV.17), that is, $z_k\in\hat V_a$, and $z_0\in\mathrm{cl}_X(V_a)$, the same conclusion. It implies the printed form `Chapter14/ZLoopCoherent · SBLocalization.HasThetaLocalEq.proposition_14_4_6_2`, since $V_a\subset\hat V_a$. *A reading*: Lemma 14.4.9 (3) cites (2) for the pairs of Θ_z, whose sequences lie in $\hat V_a$, while (2) is printed for $z_k\in V_a$. The text's proof works for $z_k\in\hat V_a$, and that is the form proved.

The setting of the proof `Chapter14/ZLoopLimits · SBLocalization.ZLimitSetting`, the facts of §14.3 it uses beyond the setting with topology: open sets $M_{b,c}$ of morphisms (the $\hat O_{b,c}$ of Proposition 14.3.4) on which $\hat\tau_{b,c}$ is locally constant and which contain every boundary morphism from $\tilde U(b)$ to $\mathrm{cl}_X\tilde U(c)$; the properness of $\mathrm{cl}_X\tilde U(b)$ ((P6)); and the local finiteness of $(|\hat V_b|)_{b\in A}$ (Proposition 14.3.8 (3)). And Definition 14.1.7 (4) for $\hat\tau$ along the boundary morphisms from $\tilde U(b)$ to $\tilde U(c)$ `Chapter14/ZLoopLimits · SBLocalization.ZSections.CompatNbhd`, slightly more than along those of $\hat V_{b,c}$, since the limit loop runs through the closures. All of these hold for the objects of §14.3 (§XIV.13).

The general statement `Chapter14/ZLoopLimitExists · SBLocalization.sections_eq_of_theta_closure` (stronger): for every $z_0\in\mathrm{cl}_X(\hat V_a)\cap\partial X$ and $(i,i')\in\Theta_{z_0}$, $s_i^{0a}=s_{i'}^{0a}$ on a neighbourhood of z_0 in ∂X. From it, the form with $z_k\in\hat V_a$ `Chapter14/ZLoopLimitExists · SBLocalization.hasThetaLocalEq_of_limit` ($\mathrm{cl}_X(V_a)\subset\mathrm{cl}_X(\hat V_a)\cap\partial X$, ∂X being closed) and the printed form `Chapter14/ZLoopLimitExists · SBLocalization.proposition_14_4_6_2_of_limit`. *Stronger*: $z_k\in\hat V_a$ instead of V_a, and every $z_0\in\mathrm{cl}_X(\hat V_a)\cap\partial X$ instead of $z_0\in\mathrm{cl}_X(V_a)$.

Proof, the text's, in Lean's order.

1. *The finite representation at z_0* `Chapter14/ZLoopLimitExists · SBLocalization.ZLimitSetting.exists_limitRep` `Chapter14/ZLoopLimits · SBLocalization.ZLimitRep`. (a) By local finiteness, a neighbourhood of $|z_0|$ meets only the $|\hat V_b|$ with b in a finite set $o\subset A$. (b) $K=\bigcup_{b\in o}\mathrm{cl}_X\hat V_b$ lies in the proper set $\bigcup_{b\in o}\mathrm{cl}_X\tilde U(b)$, a finite union of proper sets; so only finitely many objects of K are isomorphic to z_0 (Lemma 7.1.11, Part VII); let $Y\ni z_0$ be that finite set. (c) For $y\in Y$ choose neighbourhoods $Q(y)$: for each pair $b,c\in o$ with $y\in\mathrm{cl}\,\hat V_b\cap\partial X$, inside $\tilde U(b)$ and with every morphism from $Q(y)$ into $\mathrm{cl}_X\tilde U(c)$ in $M_{b,c}$ `Chapter14/ZLoopLimitExists · SBLocalization.ZLimitSetting.exists_nbhd_near` (by the properness step of Lemma 14.3.7, §XIV.11, since at y itself all such morphisms are boundary mor-

phisms from $\tilde{U}(b)$ to $\operatorname{cl}\tilde{U}(c)$, which lie in $M_{b,c}$); for each $b \in o$ with $y \notin \operatorname{cl}\hat{V}_b$, disjoint from $\operatorname{cl}\hat{V}_b$ `Chapter14/ZLoopLimitExists · SBLocalization.ZLimitSetting.exists_nbhd_yb`; and the intersection over the finitely many conditions. (d) Lemma 14.4.7 on Y inside the $Q(y)$ gives the sheets $\mathbf{O}(\psi)$. (e) Properness of K gives a neighbourhood $W \subset O(z_0)$ of z_0 such that every morphism from W into a $\hat{V}_c$ has $c \in o$ `Chapter14/ZLoopLimits · SBLocalization.ZLimitRep.mem_o_of_mem_W` and ends in $\bigcup_y O(y)$: otherwise morphisms with sources tending to z_0 and targets in K outside $\bigcup O(y)$ would have a convergent subsequence, with limit a morphism from z_0 to a point of K isomorphic to z_0, so a point of Y, inside the open $O(y)$.

2. *Sheets and correspondences.* The morphisms between points of the $O(y)$ lie in sheets, and the sheet containing a given morphism is unique `Chapter14/ZLoopLimits · EpGroupoid.NaturalRepFinite.eq_of_mem_sheet_z5` (the sheets are disjoint components). For a morphism $\omega : y \to y'$ of Y with $y \in \operatorname{cl}\hat{V}_b$, $y' \in \operatorname{cl}\hat{V}_c$, the sheet $\mathbf{O}(\omega)$ lies in $M_{b,c}$ `Chapter14/ZLoopLimits · SBLocalization.ZLimitRep.sheet_subset_M`, by the choice of $Q(y)$ (its morphisms go into $O(y') \subset \tilde{U}(c)$). A map locally constant at every point of a set is constant on every preconnected subset `Chapter14/ZLoopLimits · EpGroupoid.eq_of_isPreconnected_z5`, so $\hat{\tau}_{b,c}$ is constant on the connected sheet $\mathbf{O}(\omega)$ `Chapter14/ZLoopLimits · SBLocalization.ZLimitRep.tau_eq`.
3. *The limit loop* `Chapter14/ZLoopLimits · SBLocalization.ZLimitRep.arc_transport`. Claim: for an arc $\mathrm{Arc}(a, b, i, j, \varphi)$ with $s(\varphi) \in W$ and $z_0 \in \operatorname{cl}\hat{V}_a$, there is a morphism $\psi : z_0 \to y$ of Y with $y \in \operatorname{cl}\hat{V}_b$ and $\varphi \in \mathbf{O}(\psi)$, and along the deformed morphisms $(s|\mathbf{O}(\psi))^{-1}(y')$, $y' \in O(z_0) \cap \partial X$, the sections are transported: $s_j^{0b}(t((s|\mathbf{O}(\psi))^{-1}(y'))) = \mu((s|\mathbf{O}(\psi))^{-1}(y'), s_i^{0a}(y'))$. *Proof* by induction. At the start, $\varphi = 1_z$ with $z \in W \subset O(z_0)$ lies in the sheet of 1_{z_0}, and the deformed morphisms are units. For an appended step χ (from $\hat{V}_{b'}$ to $\hat{V}_b$, pair (j', j)): by induction $\varphi_1 \in \mathbf{O}(\psi_1)$, $\psi_1 : z_0 \to y_1$; χ starts at $t(\varphi_1) \in O(y_1)$ and ends in $\hat{V}_{b'}$, and the source of $\chi \circ \varphi_1$ is in W, so by 1 (e) it ends in some $O(y)$ and lies in a sheet $\mathbf{O}(\omega)$, $\omega : y_1 \to y$, with $y \in \operatorname{cl}\hat{V}_b$ (since $O(y)$ meets $\hat{V}_b$, and $O(y)$ misses the closures not containing y). By Lemma 14.4.7 (6), $\chi \circ \varphi_1 \in \mathbf{O}(\omega \circ \psi_1)$; put $\psi = \omega \circ \psi_1$. For $y' \in O(z_0) \cap \partial X$, the deformed $(s|\mathbf{O}(\psi))^{-1}(y')$ is the composite of the deformed φ_1 and the morphism of $\mathbf{O}(\omega)$ from its target (the key identity of Lemma 14.4.7 (6)); the latter is a boundary morphism from $\tilde{U}(b')$ to $\operatorname{cl}\tilde{U}(b)$, its correspondence is $\hat{\tau}_{b',b}(\chi)$ by step 2, so (j', j) is a pair of it, and Definition 14.1.7 (4) along it, composed with the induction hypothesis, gives the transport.
4. *Conclusion* `Chapter14/ZLoopLimits · SBLocalization.ZLimitRep.sections_eq`. Let $(i, i') \in \Theta_{z_0}$: there is $z \in W \cap \hat{V}_a$ with $i \sim_z i'$, an arc with composite 1_z. By 3, $1_z \in \mathbf{O}(\psi)$ for a morphism ψ from z_0; the unit 1_z lies in the sheet of 1_{z_0} too, so $\psi = 1_{z_0}$ by uniqueness of the sheet, and the deformed morphisms are the units $1_{y'}$. The transport gives $s_{i'}^{0a}(y') = s_i^{0a}(y')$ for $y' \in O(z_0) \cap \partial X$.

How Lean departs from the text. The text builds the limit z_0-loop (the limits of the morphisms of the z_k-loops, which exist by properness) and deforms it along ∂X. Here each step of one z_k-loop, k large (a $z \in W$), is located in a sheet of the finite representation directly; the limit loop is the chain of sheet centres ψ, and the identity of its composite is read off from the sheet of the unit. The two arguments use the same facts. Gap G.168 is closed by this proof. For the objects of §14.3 (§XIV.13), where every fact of the setting is proved, both forms hold with no hypothesis beyond the text's data: the printed one `Chapter14/ZLoopSetting · SBLocalization.ZConcrete.proposition_14_4_6_2` and the one with $z_k \in \hat{V}_a$ `Chapter14/ZLoopSetting · SBLocalization.ZConcrete.hasThetaLocalEq`.

XIV.17 Definition 14.4.8 and Lemma 14.4.9 (2017: Definition 14.8, Lemma 14.8): the relations $\approx_z$ on the closure

At points of $\mathrm{cl}_X \hat{V}_a$ outside $\hat{V}_a$ there are no z-loops; the relation $\approx_z$ records which indices are identified by loops at nearby points.

Definition 14.4.8 (restated), p. 663. Θ_z `Chapter14/ZRelationClosure · EpGroupoid.ZData.Theta`: $(i,i') \in \Theta_z$ if $z \in \mathrm{cl}\{y : i \sim_y i'\}$. The text asks for a sequence $z_k \in \hat{V}_a$ with $i \sim_{z_k} i'$ and $z_k \to z$; the closure is the same in a Fréchet–Urysohn space `Chapter14/ZRelationClosure · EpGroupoid.ZData.theta_iff_seq`, for instance a metrizable one, which the object space is. $\approx_z$ `Chapter14/ZRelationClosure · EpGroupoid.ZData.Approx`: the reflexive-transitive closure of Θ_z, that is, $i \approx_z i'$ if there is a chain $i = i_0, \dots, i_k = i'$ with $(i_p, i_{p+1}) \in \Theta_z$ (the text's last index is printed $i_p = i'$; $i_k = i'$ is meant). (14.44): $[i]_{\approx_z} = \{i' : i' \approx_z i\}$ `Chapter14/ZRelationClosure · EpGroupoid.ZData.approxClass`. *Restated*: closure in place of sequences, and the reflexive closure included, so that $\approx_z$ is reflexive also where Θ_z is empty (off $\mathrm{cl}\,\hat{V}_a$, where nothing is asked).

$\approx_z$ is an equivalence relation `Chapter14/ZRelationClosure · EpGroupoid.ZData.approx_equivalence`, as the text calls it. Θ_z is symmetric `Chapter14/ZRelationClosure · EpGroupoid.ZData.theta_symm`, because $\sim_y$ is (§XIV.14); so the reflexive-transitive closure is symmetric (reverse the chain), and it is reflexive and transitive by construction. On $\mathrm{cl}_X \hat{V}_a$, Θ_z is itself reflexive `Chapter14/ZRelationClosure · EpGroupoid.ZData.theta_refl`: $i \sim_y i$ for every $y \in \hat{V}_a$, so $z \in \mathrm{cl}\,\hat{V}_a = \mathrm{cl}\{y : i \sim_y i\}$.

Lemma 14.4.9 (same; (3) stronger), pp. 663–664.

(1) `Chapter14/ZRelationClosure · EpGroupoid.ZData.lemma_14_4_9_1`: for $z \in \hat{V}_a$, $i \sim_z i'$ implies $i \approx_z i'$. *Proof*: by Proposition 14.4.6 (1), $i \sim_y i'$ for y near z, so z is in the closure of that set and $(i,i') \in \Theta_z$.

(2) `Chapter14/ZRelationClosure · EpGroupoid.ZData.lemma_14_4_9_2`: $i \approx_z i'$ implies $g(i) \approx_{g*z} g(i')$. *Proof*: for a single step `Chapter14/ZRelationClosure · EpGroupoid.ZData.theta_smul`, the set $\{y : g(i) \sim_y g(i')\}$ contains $g * \{y : i \sim_y i'\}$ by Lemma 14.4.5, and $z \mapsto g * z$ is continuous on $\tilde{U}(a)$, which contains $\mathrm{cl}\,\hat{V}_a$ (14.33); so $g * z$ is in the closure of the image. Chains map to chains. *Classes* `Chapter14/ZRelationClosure · EpGroupoid.ZData.lemma_14_4_9_2_class`: $[g(i)]_{\approx_{g*z}} = g([i]_{\approx_z})$ for $z \in \mathrm{cl}_X \hat{V}_a$; the reverse inclusion applies (2) to g^{-1} and uses $g^{-1} * (g * z) = z$, valid on $\tilde{U}(a) \supset \mathrm{cl}\,\hat{V}_a$.

(4) `Chapter14/ZRelationClosure · EpGroupoid.ZData.lemma_14_4_9_4`: for $i \in I_a$ and $z_0 \in \mathrm{cl}_X \hat{V}_a$ there is an open $\tilde{Q}(z_0) \ni z_0$ in $\tilde{U}(a)$ with $[i]_{\sim_z} \subset [i]_{\approx_{z_0}}$ for $z \in \hat{V}_a \cap \tilde{Q}(z_0)$. *Proof*: for each of the finitely many $i' \notin [i]_{\approx_{z_0}}$, $(i',i) \notin \Theta_{z_0}$ (as $\Theta_{z_0} \subset \approx_{z_0}$), so z_0 has an open neighbourhood missing $\{y : i' \sim_y i\}$. Intersect these with $\tilde{U}(a)$. At z in the intersection, every $i' \sim_z i$ is in $[i]_{\approx_{z_0}}$. For all i at once `Chapter14/ZRelationClosure · EpGroupoid.ZData.lemma_14_4_9_4_all`, intersect over the finite I_a. The text argues by contradiction with sequences; this is the same argument with neighbourhoods.

(3), p. 663: for $z \in \mathrm{cl}_X(V_a)$ and $i \approx_z i'$, $s_i^{0a} = s_{i'}^{0a}$ on $U(a)$ near z. *Proof*, the text's: chain Proposition 14.4.6 (2), in the form with $z_k \in \hat{V}_a$, along the steps of Θ_z, intersecting the finitely many neighbourhoods. With that form as a hypothesis `Chapter14/ZLoopCoherent · SBLocalization.lemma_14_4_9_3_hyp`, and, the form being proved (§XIV.16), unconditionally and for every $z \in \mathrm{cl}_X(\hat{V}_a) \cap \partial X$ `Chapter14/ZLoopLimitExists · SBLocalization.lemma_14_4_9_3_of_limit`, from the general statement of §XIV.16. *Stronger*: $z \in \mathrm{cl}_X(\hat{V}_a) \cap \partial X$, which contains $\mathrm{cl}_X(V_a)$.

XIV.18 Proposition 14.4.10, Definition 14.4.11 and Remark 14.4.12 (2017: Proposition 14.6, Definition 14.9, Remark 14.6): coherent neighbourhood systems

The natural action on open sets. For a natural neighbourhood N of x and $O \subset N$: $g*O = N \cap \Phi_{g^{-1}}^{-1}(O)$, so $g * O$ is open when O is `Chapter14/ZRelationClosure · EpGroupoid.NatNbhd.isOpen_image_Φ`, and $(gh) * O = g * (h * O)$ `Chapter14/ZRelationClosure · EpGroupoid.NatNbhd.image_Φ_mul`. The action preserves ∂X `Chapter14/ZLoopCoherent · SBLocalization.Φ_mem_boundary_z4` (the degeneracy index is invariant) and maps $\mathrm{cl}_X \hat{V}_a$ and $\mathrm{cl}_X(V_a)$ into themselves `Chapter14/ZLoopCoherent · SBLocalization.mapsTo_Φ_closure_z4` (continuity on $\tilde{U}(a) \supset \mathrm{cl}\,\hat{V}_a$).

Equivariant shrinking `Chapter14/ZRelationClosure · EpGroupoid.NatNbhd.exists_equivariant_nbhds`, the step of Proposition 14.4.10 (2) the text leaves to the reader. *Statement*: let $C \subset N$ be G_x-invariant and $P(z, O)$ a property of neighbourhoods of $z \in C$ that passes to smaller sets and is carried along by the action ($P(z,O) \Rightarrow P(g*z, g*O)$); if every $z \in C$ has an open $O \ni z$ with $P(z,O)$, there are open $O(z) \ni z$, $O(z) \subset N$, with $P(z, O(z))$, $O(g*z) = g*O(z)$, and $O(z) \cap O(g*z) = \emptyset$ whenever $g*z \neq z$. *Proof.*

1. *At one point $w \in C$.* Start from O with $P(w,O)$, intersected with N. The finitely many points $g*w \neq w$ are distinct from w; the object space is Hausdorff, so shrink O so that $O \cap g*O = \emptyset$ for each such g (choose O inside a neighbourhood U_g of w with $U_g \cap g*U_g = \emptyset$, which exists by continuity of the action and $g*w \neq w$). Then intersect over the stabilizer: $O_w = \bigcap_{h*w=w} h*O$. It is open, contains w, is smaller than O (so $P(w, O_w)$ and the separation persist), and is invariant under the stabilizer.
2. *Transport from orbit representatives.* Choose one w in each G_x-orbit of C and put $O(g*w) = g*O_w$. This is well defined: if $g*w = g'*w$, then $g^{-1}g'$ fixes w and $g'*O_w = g*(g^{-1}g')*O_w = g*O_w$. P holds by the equivariance of P; $O(h*z) = h*O(z)$ by construction.
3. *Separation.* If $z = h*w$ and $g*z \neq z$, then $k = h^{-1}gh$ moves w, so $O_w \cap k*O_w = \emptyset$; applying h, $O(z) \cap O(g*z) = \emptyset$.

Proposition 14.4.10 (same) `Chapter14/ZLoopCoherent · SBLocalization.proposition_14_4_10_hyp`, p. 664. *Statement*: for $a \in A$, every $z \in \mathrm{cl}_X \hat{V}_a$ has an open $\tilde{O}(z) \ni z$ with (1) $\tilde{O}(z) \subset \tilde{U}(a)$; (2) $\tilde{O}(g*z) = g*\tilde{O}(z)$, and $\tilde{O}(z) \cap \tilde{O}(g*z) = \emptyset$ if $g*z \neq z$; (3) $[i]_{\sim_y} \subset [i]_{\approx_z}$ for $y \in \tilde{O}(z) \cap \hat{V}_a$; (4) for $z \in \mathrm{cl}_X(V_a)$ and $i \approx_z i'$, $s_i^{0a} = s_{i'}^{0a}$ on $\tilde{O}(z) \cap U(a)$. *Proof.* The text calls it immediate from Lemma 14.4.9. Apply the equivariant shrinking with $C = \mathrm{cl}_X \hat{V}_a$ (invariant, inside $\tilde{U}(a)$ by (14.33)) and $P(z,O)$ the conjunction of (3) at z and (4) at z.

1. *Existence at each z*: (3) holds on the $\tilde{Q}(z)$ of Lemma 14.4.9 (4) for all i; (4) holds on a neighbourhood by Lemma 14.4.9 (3), for each of the finitely many pairs $i \approx_z i'$; intersect.
2. *Shrinking*: both are statements about all points of O.
3. *Action*: (3) at $g*z$ on $g*O$: for $y \in O \cap \hat{V}_a$, $[i]_{\sim_{g*y}} = g([g^{-1}(i)]_{\sim_y}) \subset g([g^{-1}(i)]_{\approx_z}) = [i]_{\approx_{g*z}}$ by Lemma 14.4.5 and Lemma 14.4.9 (2), with $\hat{V}_a$ invariant. (4) at $g*z$: if $i \approx_{g*z} i'$, then $g^{-1}(i) \approx_z g^{-1}(i')$, so $s^{0a}_{g^{-1}(i)} = s^{0a}_{g^{-1}(i')}$ on $O \cap U(a)$; by (14.45), $s_i^{0a}(g*y) = \mu(\Gamma(g,y), s^{0a}_{g^{-1}(i)}(y))$, and the same for i', so they agree on $g*(O \cap U(a)) = g*O \cap U(a)$, the action preserving ∂X.

The hypothesis of this form, Proposition 14.4.6 (2) with $z_k \in \hat{V}_a$, is used only in step 1 through Lemma 14.4.9 (3). Unconditionally `Chapter14/ZLoopLimitExists · SBLocalization.proposition_14_4_10_of_limit`, by §XIV.16; for the objects of §14.3, with no hypothesis beyond the text's data `Chapter14/`

ZLoopSetting · SBLocalization.ZConcrete.proposition_14_4_10.

Definition 14.4.11 (restated) Chapter14/ZLoopCoherent · SBLocalization.ZCoherentNbhdSystem, p. 664. A coherent neighbourhood system for $\mathrm{cl}_X(\hat V_a) \subset \tilde U(a)$ (the 2017 text calls it a good neighbourhood system) is a family of open $\tilde O(z) \ni z$, $z \in \mathrm{cl}_X \hat V_a$, with (1), (2), (3) for $z \in \hat V_a$ as printed, and (4). *Existence*, "in view of Proposition 14.4.10": from the form with $z_k \in \hat V_a$ Chapter14/ZLoopCoherent · SBLocalization.exists_zCoherentNbhdSystem_hyp; unconditionally Chapter14/ZLoopLimitExists · SBLocalization.exists_zCoherentNbhdSystem_of_limit; for the objects of §14.3 Chapter14/ZLoopSetting · SBLocalization.ZConcrete.exists_zCoherentNbhdSystem. For the zero data the hypothesis holds trivially Chapter14/ZLoopCoherent · SBLocalization.hasThetaLocalEq_zero, and a system exists Chapter14/ZLoopCoherent · SBLocalization.exists_zCoherentNbhdSystem_zero.

The abstract form used by Proposition 14.4.14. The local extension is proved over data for one fixed a Chapter14/CoherentExtension · SBLocalization.LocalExtensionBase: $\tilde U(a)$ with the natural G_a-action, an open invariant $\hat V_a \subset \tilde U(a)$, a finite I_a with a G_a-action, boundary sections face-wise sc⁺ on $U(a) = \tilde U(a) \cap \partial X$ with (14.45), relations $\sim_y$ with Lemma 14.4.5, and relations $\approx_z$ as parameters. Over them, a coherent neighbourhood system Chapter14/CoherentExtension · SBLocalization.CoherentNbhdSystem has (1), (3) for $z \in \mathrm{cl}_X \hat V_a$, and (4) as fields; (2) is a separate predicate Chapter14/CoherentExtension · SBLocalization.CoherentNbhdSystem.IsEquivariant, since the proof of Proposition 14.4.14 below does not use it. *A reading*: (3) is printed for $z \in \hat V_a$; Proposition 14.4.10 (3) states it for $z \in \mathrm{cl}_X \hat V_a$, and the proof of Proposition 14.4.14 uses it at points of the closure; we read $z \in \mathrm{cl}_X \hat V_a$, presumably what is meant. The data come from the setting of §XIV.13 Chapter14/CoherentExtension · SBLocalization.LocalExtensionBase.ofZSetup, with $\sim_y$ the relation of Definition 14.4.4 and Lemma 14.4.5 discharged; and from the boundary sections Chapter14/ZDataLocalExtension · SBLocalization.ZSections.toLocalExtensionBase, with $\approx_z$ that of Definition 14.4.8 and the face-wise sc⁺ condition of Definition 14.1.3 (1) as input. The system in this form, with (2), comes from Proposition 14.4.10 Chapter14/ZDataLocalExtension · SBLocalization.coherentNbhdSystem_hyp, and unconditionally Chapter14/ZLoopLimitExists · SBLocalization.coherentNbhdSystem_of_limit. *Witness* of the abstract form at every boundary point of a tame X Chapter14/CoherentExtension · SBLocalization.exists_coherentNbhdSystem_zero: a good V_0 at x contains a good V with $\mathrm{cl}\, V \subset V_0$ (Lemma 14.2.1), and $\tilde U(x) = V_0$, $\hat V_x = V \ni x$ with zero sections, one index and trivial relations carry the system $\tilde O(z) = V_0$.

Remark 14.4.12 (2017: Remark 14.6), p. 664, explains the meaning of the conditions (sections constant on the classes near z can be extended compatibly) and has nothing to prove.

XIV.19 Lemma 14.4.13 (2017: Lemma 14.9): the sections near an orbit

Fix a coherent neighbourhood system and $z \in \mathrm{cl}_X(\hat V_a) \cap \partial X$ with orbit $[z] = G_a * z$. The text sets $\tilde O([z]) = \bigcup_{z' \in [z]} \tilde O(z')$, a disjoint union Chapter14/ZLoopCoherent · SBLocalization.ZCoherentNbhdSystem.disjoint_orbit: distinct points of one orbit have disjoint neighbourhoods, by (2).

Lemma 14.4.13 (narrower in (2)), p. 666. The $\approx_{z'}$-classes partition I_a Chapter14/ZLoopCoherent · SBLocalization.approxClass_eq_or_disjoint, $\approx_{z'}$ being an equivalence relation: two classes are equal or disjoint.

(1) Chapter14/ZLoopCoherent · SBLocalization.lemma_14_4_13_1: an element g of the stabilizer $G_a(z')$ maps $[i]_{\approx_{z'}}$ onto $[g(i)]_{\approx_{z'}}$, so it permutes the classes. *Proof*: Lemma 14.4.9 (2) with $g * z' = z'$.

(2) Chapter14/ZLoopCoherent · SBLocalization.lemma_14_4_13_2: for $z' \in \mathrm{cl}_X(V_a)$ and $g \in G_a(z')$ fixing the class $[i]_{\approx_{z'}}$, $s_i^{0a}(g * y) = \mu(\Gamma(g, y), s_i^{0a}(y))$ for $y \in \tilde O(z') \cap \partial X$. *Proof*: within one class the sections

agree on $\tilde{O}(z')\cap\partial X$ `Chapter14/ZLoopCoherent · SBLocalization.lemma_14_4_13_classSection`, by (4) of the system (the text recalls this as the definition of the sections $s_j^{z'}$ of the proof). $g(i)$ is in the class of i; by (14.45), $s^{0a}_{g(i)}(g*y)=\mu(\Gamma(g,y),s_i^{0a}(y))$; and $g*y\in\tilde{O}(g*z')\cap\partial X=\tilde{O}(z')\cap\partial X$, where $s^{0a}_{g(i)}=s_i^{0a}$. *Narrower*: the text states (2) for every $z\in\mathrm{cl}_X(\hat{V}_a)\cap\partial X$. The proof uses Definition 14.4.11 (4), which covers only points of $\mathrm{cl}_X(V_a)$, and a point of $\mathrm{cl}_X(\hat{V}_a)\cap\partial X$ need not lie in $\mathrm{cl}_X(V_a)$. Presumably $z\in\mathrm{cl}_X(V_a)$ is meant; it is what Proposition 14.4.14 uses. The printed (2) at the other points would need a system with (4) there, which the stronger Lemma 14.4.9 (3) of §XIV.17 permits (about 90 lines, not done, not needed).

(3) `Chapter14/ZLoopCoherent · SBLocalization.lemma_14_4_13_3`: for $g\in G_a(z')$ and every i, $s^{0a}_{g(i)}(g*y)=\mu(\Gamma(g,y),s_i^{0a}(y))$ for $y\in\tilde{O}(z')\cap\partial X$. This is (14.45) on $\tilde{O}(z')\cap\partial X\subset U(a)$; it relates the class of i to the class $g([i])=[g(i)]$ when they differ.

(4) `Chapter14/ZLoopCoherent · SBLocalization.lemma_14_4_13_4`: for $z''=g*z'$, the sections over $\tilde{O}(z'')\cap\partial X$ are determined by those over $\tilde{O}(z')\cap\partial X$. *Proof*: every point of $\tilde{O}(z'')\cap\partial X=g*\tilde{O}(z')\cap\partial X$ is $g*y$ with $y\in\tilde{O}(z')\cap\partial X$, and there $s^{0a}_{g(i)}(g*y)=\mu(\Gamma(g,y),s_i^{0a}(y))$ by (14.45).

The lemma serves the text's construction of Proposition 14.4.14 orbit by orbit. The Lean proof of Proposition 14.4.14 (§XIV.20) does not go orbit by orbit and uses none of (1)–(4); they are proved as printed (with the reading of (2)) for completeness.

XIV.20 Proposition 14.4.14 (2017: Proposition 14.7): the local extension on $\hat{V}_a$

Proposition 14.4.14 (restated) `Chapter14/CoherentExtension · SBLocalization.proposition_14_4_14`, pp. 667–671. *Statement*: let every object lie in a tame strong bundle chart and let the object M-polyfold admit sc-smooth partitions of unity (the hypotheses of Proposition 14.1.4, §XIV.3). For the data of a fixed a and a coherent neighbourhood system (abstract form, (1), (3), (4)) there are sc$^+$-sections $\hat{s}_i^a$, $i\in I_a$, on $\hat{V}_a$ with $\hat{s}^a_{g(i)}(g*y)=\mu(\Gamma(g,y),\hat{s}_i^a(y))$ on $\hat{V}_a$, (1) $\hat{s}_i^a=s_i^{0a}$ on $V_a=\hat{V}_a\cap\partial X$, and (2) $\hat{s}_i^a(z)=\hat{s}_{i'}^a(z)$ whenever $i\sim_z i'$, $z\in\hat{V}_a$. *Restated*: "a local sc$^+$ symmetric section structure on $\hat{V}_a$" is read as sc$^+$-sections with the symmetry of Definition 13.2.5 (1) (Part XIII); the weights and the functor $\hat{\Lambda}_a$ are defined from them in §14.5.

The text's proof builds, on each $\tilde{O}([z])$, sections constant on the $\approx_{z'}$-classes and equivariant under G_a, class by class and orbit by orbit (using Lemma 14.4.13), and glues them with a G_a-invariant partition of unity subordinate to the $\tilde{O}([z])$. *The Lean proof* glues non-equivariant pieces with an ordinary partition of unity and then averages over G_a, as in Proposition 14.1.4.

1. *(4) for the equivalence closure* `Chapter14/CoherentExtension · SBLocalization.CoherentNbhdSystem.eqvGen_s0`: for $z\in\mathrm{cl}_X(V_a)$, if i and i' are related by the equivalence relation generated by $\approx_z$, then $s_i^{0a}=s_{i'}^{0a}$ on $\tilde{O}(z)\cap U(a)$; equality is an equivalence relation, so (4) passes to the generated one. Thus $\approx_z$ need not be an equivalence relation for this proof.
2. *Local pieces* `Chapter14/CoherentExtension · SBLocalization.CoherentNbhdSystem.exists_local_piece`: every object y has an open $U\ni y$ with sc$^+$-sections σ_i of P that equal s_i^{0a} on $U\cap\hat{V}_a\cap\partial X$ and are constant on the $\sim_z$-classes at every $z\in U\cap\hat{V}_a$. Three cases.
   (a) $y\in\mathrm{cl}_X(V_a)$. Take an open $G\ni y$ with $\mathrm{cl}\,G\subset\tilde{O}(y)$ (regularity). Choose a representative $r(i)$ of the class of each i under the equivalence relation generated by $\approx_y$. The section $s^{0a}_{r(i)}$ is face-wise sc$^+$ on $\tilde{O}(y)\cap U(a)$, so it has an sc$^+$ extension $\bar{s}_{r(i)}$ equal to it on $G\cap\partial X$ (the partition-

of-unity step of Proposition 14.1.4, §XIV.3). Put $U = G$ and $\sigma_i = \bar{s}_{r(i)}$. On $G \cap \hat{V}_a \cap \partial X$, $\sigma_i = s^{0a}_{r(i)} = s^{0a}_i$ by step 1. At $z \in G \cap \hat{V}_a$, $i \sim_z i'$ implies $i' \in [i]_{\approx_y}$ by (3), so $r(i) = r(i')$ and $\sigma_i = \sigma_{i'}$.

(b) $y \in \mathrm{cl}_X(\hat{V}_a) \setminus \mathrm{cl}_X(V_a)$. $U = \tilde{O}(y) \setminus \mathrm{cl}_X(V_a)$, $\sigma_i = 0$. $U \cap \hat{V}_a \cap \partial X \subset U \cap V_a = \emptyset$, so nothing is to be matched, and zero sections are constant on every class.

(c) $y \notin \mathrm{cl}_X \hat{V}_a$. U the complement of $\mathrm{cl}_X \hat{V}_a$, $\sigma_i = 0$; nothing is asked.

3. *Gluing.* Choose an sc-smooth partition of unity (ρ_k) subordinate to the cover by the sets U of step 2, and put $\sigma_i = \sum_k \rho_k \sigma^k_i$, an sc⁺-section (a locally finite sum of products of sc-smooth functions with sc⁺-sections). On $\hat{V}_a \cap \partial X$ each piece with $\rho_k \neq 0$ equals s^{0a}_i, so the sum does. A glued section takes equal values for i, i' wherever every piece with non-zero weight does `Chapter14/CoherentExtension · SBLocalization.glueSection_congr_at`; so $\sigma_i(z) = \sigma_{i'}(z)$ when $i \sim_z i'$.
4. *Averaging over G_a.* $\hat{s}^a_i$ is the average of §XIV.3 applied to (σ_i) on the invariant $\hat{V}_a$. It is sc⁺ and equivariant (§XIV.3, stage 2). It still extends s^{0a}, because s^{0a} is equivariant on V_a by (14.45), and the average of an equivariant family is itself. It still satisfies (2): if $i \sim_z i'$, then $g(i) \sim_{g*z} g(i')$ by Lemma 14.4.5, so each translate $\mu(\Gamma(g,z)^{-1}, \sigma_{g(i)}(g * z))$ agrees for i and i'.

Consequences of the departure. Definition 14.4.11 (2) is not needed, nor Lemma 14.4.13, nor a G_a-invariant partition of unity; $\approx_z$ need not be an equivalence relation; and (4) is used only at points of $\mathrm{cl}_X(V_a)$, as printed, since the other points of $\mathrm{cl}_X \hat{V}_a$ get neighbourhoods missing $\mathrm{cl}_X(V_a)$.

For the setting of §14.4. With Proposition 14.4.6 (2) as a hypothesis `Chapter14/ZDataLocalExtension · SBLocalization.proposition_14_4_14_of_hyp`; unconditionally, from the facts of §14.3 and Definition 14.1.7 (4) `Chapter14/ZLoopLimitExists · SBLocalization.proposition_14_4_14_of_limit`; and for the objects of §14.3 `Chapter14/ZLoopSetting · SBLocalization.ZConcrete.proposition_14_4_14`, with $\hat{s}^a_i$ equal to the sections of the tuple on $\hat{V}_a \cap \partial X$, under the hypotheses of Proposition 14.1.4 only. There the boundary sections are face-wise sc⁺ on $U(a)$ `Chapter14/ZLoopSetting · SBLocalization.ZConcrete.isFaceScPlus`, by Definition 14.1.3 (1) for the tuple, restricted to $\tilde{U}(a) \cap \partial X \subset U^0(a)$.

XIV.21 Lemma 14.5.1 and (14.53) (2017: Lemma 14.10): the cut-offs

§14.5 transports the local extensions of §14.4 from the $\hat{V}_a$ to every $\hat{V}_b$, cut off by functors β_a, sums them, and assembles the result into a structurable multisection on X.

Lemma 14.5.1 (stronger) `Chapter14/BoundaryCover · EpGroupoid.lemma_14_5_1`, p. 671. *Statement*: let X admit sc-smooth partitions of unity (Definition 7.5.5, Part VII), B a closed saturated set of objects, $A \subset B$, and $\hat{V}_a$, $a \in A$, open with $B \subset \bigcup_{a \in A} \pi^{-1}(\pi(\hat{V}_a))$. There are sc-smooth functors $\beta_a : X \to [0,1]$ ($\beta_a(s\varphi) = \beta_a(t\varphi)$ for every morphism) with (1) $\mathrm{supp}\,\beta_a \subset \pi^{-1}(\pi(\hat{V}_a))$; (2) every object has a saturated open neighbourhood on which only finitely many β_a are not identically 0; (3) $\sum_{a \in A} \beta_a = 1$ on B. *Stronger*: the tameness of X, part of the text's setting, is not used.

Proof, the text's.

1. *The cover.* For each object x, let $U_x = \pi^{-1}(\pi(\hat{V}_x))$, the saturation of $\hat{V}_x$, if $x \in A$, and $U_x = X \setminus B$ otherwise. Each U_x is open (the saturation of an open set is open, §XIV.11) and saturated (a preimage under π, resp. the complement of the saturated B). They cover X: a point of B lies in some saturation by hypothesis, and a point off B lies in $X \setminus B = U_y$ for any $y \notin A$, in particular for itself (it is not in $B \supset A$).

2. *The partition.* Definition 7.5.5 for ep-groupoids gives an sc-smooth partition of unity (ρ_x) by functors, subordinate to a saturated open cover, locally finite on saturated open sets. Put $\beta_a = \rho_a$ for $a \in A$.
3. *(1)* is subordination. *(2)* is the local finiteness of (ρ_x). *(3)*: at $y \in B$, every ρ_x with $x \notin A$ vanishes, since its support lies in $X \setminus B$; so $\sum_{a\in A} \beta_a(y) = \sum_x \rho_x(y) = 1$.

(14.53), p. 672: $\mathrm{cl}_X\{y \in \tilde{U}(a) : \beta_a(y) \neq 0\} \subset \hat{V}_a$. The text obtains it by shrinking the cover. For the objects of §14.3 no shrinking is needed: it follows from (1), by a property of natural neighbourhoods.

Closure points of a natural neighbourhood `Chapter14/AssemblyInputInstance · SBLocalization.tgt_mem_of_closure_a6`: for a natural neighbourhood $\tilde{U}(x)$ and an invariant $V \subset \tilde{U}(x)$, a morphism φ from a point of V to a point of $\mathrm{cl}_X \tilde{U}(x)$ ends in V. *Proof*: t is a local homeomorphism, hence open, so φ is a limit of morphisms ψ with $s(\psi) \in V$ (open condition near φ along the sheet) and $t(\psi) \in \tilde{U}(x)$; such ψ are $\Gamma(g_\psi, s(\psi))$ for some $g_\psi \in G_x$, by the naturality of the representation. G_x is finite, so one g occurs for ψ arbitrarily close to φ. The condition $\Gamma(g, s(\psi)) = \psi$ is closed near φ (both sides continuous, the morphism space Hausdorff), so $\varphi = \Gamma(g, s(\varphi))$, whose target $g * s(\varphi)$ lies in V by invariance.

(14.53) from (1) `Chapter14/AssemblyInputInstance · SBLocalization.closure_support_subset_a6`: if $\operatorname{supp}\beta \subset \pi^{-1}(\pi(V))$ for an invariant open $V \subset \tilde{U}(x)$, then $\mathrm{cl}_X\{y \in \tilde{U}(x) : \beta(y) \neq 0\} \subset V$. *Proof*: a point y of the closure lies in $\mathrm{cl}\,\tilde{U}(x)$ and in $\operatorname{supp}\beta$, so it is the target of a morphism from a point of V `Chapter14/AssemblyInputInstance · SBLocalization.exists_mor_of_ne_zero_a6` (that is what $y \in \pi^{-1}(\pi(V))$ says); by the previous lemma, $y \in V$.

For the objects of §14.3 `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.exists_betaSpec`: Lemma 14.5.1 with $B = \partial X$ (closed and saturated, §XIV.11), A and the $\hat{V}_a$ of Proposition 14.3.8 (whose orbits cover $|\partial X|$ by (3)), and $\beta_a = 0$ for $a \notin A$, gives cut-offs with all the properties the transport needs `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.BetaSpec`: sc-smooth functors into $[0,1]$, (1)–(3), and (14.53) for the $\hat{V}_a$ themselves, by the lemma above with $V = \hat{V}_a \subset \tilde{U}(a)$ invariant.

XIV.22 Lemma 14.5.2 and Remark 14.5.3 (2017: Lemma 14.11, Remark 14.7): the cut-offs over ∂X

Lemma 14.5.2, p. 672, says that for Λ structurable over ∂X and the β_a of Lemma 14.5.1, the family $(\beta_a|\partial X) \odot \Lambda$ is commensurable (Definition 13.3.11, Part XIII) and its sum is Λ. *As formalized* (narrower): the identity the proof of Theorem 14.1.9 uses, for the summed sections, $\tilde{s}^b_j = s^{0b}_j$ on $\hat{V}_b \cap \partial X$ `Chapter14/TransportedSum · SBLocalization.AssemblyInput.usec_boundary`, proved below once the summed sections are defined. The multisection form, the commensurable family over ∂X and its sum, is not built: it needs the boundary analogue of the commensurability data of §13.3 (about 120 lines), and nothing uses it (gap G.172, §XIV.29).

The data of §§14.3–14.5 `Chapter14/TransportedSum · SBLocalization.AssemblyInput`, for Λ structurable over ∂X, as the assembly uses them: a setting of §14.4 with an input of Proposition 14.5.4 (§XIV.23) whose cut-offs satisfy Lemma 14.5.1 (1)–(3); the values of $\hat{\tau}$ finite in number and equivariant for the bi-action (Proposition 14.3.4); non-empty index sets I_b; the representation of Λ by the boundary sections s^{0b} on $\hat{V}_b \cap \partial X$ (Definition 14.1.3 (3)); and the functor property of Λ over ∂X.

A closed set off which everything vanishes. $K_a = \mathrm{cl}\{y \in \tilde{U}(a) : \beta_a(y) \neq 0\} \subset \hat{V}_a$ (14.53), and $C = \bigcup_{a\in A} t(s^{-1}(K_a))$ `Chapter14/TransportedSum · SBLocalization.AssemblyInput.C`, the set of

points isomorphic to a point where some cut-off is non-zero near its own $\widehat{V}_a$. *C is closed* `Chapter14/TransportedSum · SBLocalization.AssemblyInput.isClosed_C`: each $t(s^{-1}(K_a))$ is closed, K_a being a closed subset of the proper cl $\widetilde{U}(a)$ ((P6)), and the family is locally finite by Lemma 14.5.1 (2) (a saturated neighbourhood on which only finitely many β_a are non-zero meets only finitely many of these saturated sets). *C is saturated* `Chapter14/TransportedSum · SBLocalization.AssemblyInput.isSaturated_C`. *Every transported section vanishes off C* `Chapter14/TransportedSum · SBLocalization.AssemblyInput.tsec_eq_zero_of_not_mem_C`: a value $\mu(\varphi, \beta_a(s\varphi)\widehat{s}^a_i(s\varphi))$ with $t(\varphi) \notin C$ has $s(\varphi) \notin K_a$, so $\beta_a(s\varphi) = 0$. This is how the text's points $|x| \notin \bigcup_b |\widehat{V}_b|$, where "all sections vanish", are handled.

The sum `Chapter14/TransportedSum · SBLocalization.AssemblyInput.usec`: $\widetilde{s}^b_j(y) = \sum_{a\in A} \widetilde{s}^a_{b,j}(y)$ in the fibre over y. *Locally finite* `Chapter14/TransportedSum · SBLocalization.AssemblyInput.exists_finite_tsec`: every y_0 has an open $Q \ni y_0$ and a finite $F \subset A$ with $\widetilde{s}^a_{b,j} = 0$ on Q for $a \notin F$, by Lemma 14.5.1 (2) (if β_a vanishes on a saturated neighbourhood, every transport of $\beta_a \widehat{s}^a$ vanishes there). On Q the sum is a finite section sum `Chapter14/TransportedSum · SBLocalization.AssemblyInput.usec_eq_sectionSum`, so *sc⁺ on $\widehat{V}_b$* `Chapter14/TransportedSum · SBLocalization.AssemblyInput.isScPlusSectionOn_usec`, a finite sum of sc⁺-sections (Proposition 14.5.4) being sc⁺. *Equivariant* `Chapter14/TransportedSum · SBLocalization.AssemblyInput.usec_equivariant` and *compatible with $\widehat{\tau}$* `Chapter14/TransportedSum · SBLocalization.AssemblyInput.usec_compat`: $\mu(\varphi, \cdot)$ is linear on the fibres and commutes with the finite sum, and each summand has the property by Proposition 14.5.4 (4) and the equivariance there.

Proof of the sum identity (Lemma 14.5.2 as used). For $y \in \widehat{V}_b \cap \partial X$: $\widetilde{s}^a_{b,j}(y) = \beta_a(y) s^{0b}_j(y)$ by Proposition 14.5.4 (3), so $\widetilde{s}^b_j(y) = (\sum_a \beta_a(y)) s^{0b}_j(y) = s^{0b}_j(y)$ by Lemma 14.5.1 (3).

The cut-off of the size control, folded into the sections: for an sc-smooth functor σ, $\sigma\widetilde{s}^b_j$ `Chapter14/TransportedSum · SBLocalization.AssemblyInput.ssec` is again sc⁺ on $\widehat{V}_b$, equivariant and compatible with $\widehat{\tau}$ (σ is invariant under morphisms), and zero off C.

Remark 14.5.3 (2017: Remark 14.7), p. 672, comments on the role of the cut-offs and states nothing to prove.

XIV.23 Proposition 14.5.4 (2017: Proposition 14.8): the transport

The input `Chapter14/TransportStatement · SBLocalization.TransportInput`, over a combinatorial setting of §14.4: the open sets $\widehat{V}_a$; the properness of cl $\widetilde{U}(a)$; $\widehat{\tau}$ locally constant; cut-offs β_a, sc-smooth functors with (14.53); boundary sections s^{0a} with Definition 14.1.7 (4) for $\widehat{\tau}$ over ∂X; and local extensions $\widehat{s}^a$, the output of Proposition 14.4.14: sc⁺ on $\widehat{V}_a$, G_a-equivariant, equal to s^{0a} on V_a, and equal on $\sim_z$-related indices.

Proposition 14.5.4 (same) `Chapter14/TransportStatement · SBLocalization.proposition_14_5_4_statement`, p. 673. *Statement*: for every $a \in A$ there are sections $\widetilde{s}^a_{b,j}$, $b \in A$, $j \in I_b$, sc⁺ and G_b-equivariant on $\widehat{V}_b$, with (1) $\widetilde{s}^a_{a,i} = \beta_a \widehat{s}^a_i$ on $\widehat{V}_a$; (2) the support of $\widetilde{s}^a_{a,i}$ closed in X and contained in $\widehat{V}_a$, read as: $\widetilde{s}^a_{a,i}$ vanishes off a closed subset of X contained in $\widehat{V}_a$; (3) $\widetilde{s}^a_{b,j} = \beta_a s^{0b}_j$ on $V_b = \widehat{V}_b \cap \partial X$; (4) $\widetilde{s}^a_{b',\beta(k)}(t\varphi) = \mu(\varphi, \widetilde{s}^a_{b,\alpha(k)}(s\varphi))$ for $\varphi \in \widehat{V}_{b,b'}$ and every representative $[I_b \xleftarrow{\alpha} K \xrightarrow{\beta} I_{b'}]$ of $\widehat{\tau}_{b,b'}(\varphi)$. "Symmetric sc⁺-section structure on $\widehat{V}_b$" is read as sc⁺ and G_b-equivariant (Definition 13.2.5 (1)). *The statement is consistent* `Chapter14/TransportStatement · SBLocalization.proposition_14_5_4_statement_of_zero`: for vanishing data it holds with $\widetilde{s} = 0$, multiples of zero sections being zero `Chapter14/TransportStatement · SBLocalization.sectionSmul_fiberZero_gl`.

Proved Chapter14/TransportProof · SBLocalization.TransportInput.proposition_14_5_4, for every input whose cut-offs satisfy Lemma 14.5.1 (1) Chapter14/TransportProof · SBLocalization.TransportInput.SuppInSat: $\beta_a(y) \neq 0$ only if y is the target of a morphism with source in $\hat{V}_a$. The input records Lemma 14.5.1 only through (14.53); (1) itself is needed for (3), at boundary points of $\hat{V}_b$ not reached from $\hat{V}_a$. The cut-offs of §XIV.21 have it; so does $\beta \equiv 0$ Chapter14/TransportProof · SBLocalization.TransportInput.suppInSat_of_zero. Gap G.170 is closed by this proof.

Proof, the text's, with the transport defined through arcs.

1. *The cut-off local extensions.* $\beta_a \hat{s}^a_i$, extended by 0 off $\hat{V}_a$, is a global section, sc$^+$ on $\hat{V}_a$ Chapter14/TransportProof · SBLocalization.TransportInput.isScPlusSectionOn_bsec (product of an sc-smooth function with an sc$^+$-section).
2. *Definition* Chapter14/TransportProof · SBLocalization.TransportInput.tsec: $\tilde{s}^a_{b,j}(y) = \mu(\varphi, \beta_a \hat{s}^a_i(s\varphi))$ for any arc $\mathrm{Arc}(a,b,i,j,\varphi)$ (§XIV.14) with $t(\varphi) = y$ Chapter14/TransportProof · SBLocalization.TransportInput.tsec_of_arc, and 0_y if there is none Chapter14/TransportProof · SBLocalization.TransportInput.tsec_of_not. A morphism from $\hat{V}_a$ to $\hat{V}_b$ with a pair (i,j) of $\hat{\tau}_{a,b}(\varphi)$ is an arc of length one Chapter14/TransportProof · SBLocalization.TransportInput.arc_of_pairs, so the definition agrees with the text's one-step form Chapter14/TransportProof · SBLocalization.TransportInput.tsec_of_pairs; and the section vanishes at points of $\hat{V}_b$ that are targets of no morphism from $\hat{V}_a$ Chapter14/TransportProof · SBLocalization.TransportInput.tsec_of_not_reach. *Why arcs*: with arcs the equivariance and (4) are immediate (append a step); the text defines the value along one morphism and proves independence by z-loops, which is the next step.
3. *Independence of the arc* Chapter14/TransportProof · SBLocalization.TransportInput.fibAct_bsec_eq, the text's z-loop argument. Let $\mathrm{Arc}(a,b,i,j,\varphi)$ and $\mathrm{Arc}(a,b,i',j,\varphi')$ end at the same point. Concatenating the second with the reversal of the first gives $\mathrm{Arc}(a,a,i',i,\varphi^{-1}\circ\varphi')$, a chain from $s(\varphi') \in \hat{V}_a$ to $s(\varphi) \in \hat{V}_a$. Both ends lie in $\tilde{U}(a)$, so $\varphi^{-1}\circ\varphi' = \Gamma(g, s\varphi')$ for some $g \in G_a$. Append $\Gamma(g^{-1}, s\varphi)$, with pair $(i, g^{-1}(i))$ by *diag*: the composite is $1_{s\varphi'}$, a z-loop, so $i' \sim_{s\varphi'} g^{-1}(i)$. By Proposition 14.4.14 (2), $\hat{s}^a_{i'}(s\varphi') = \hat{s}^a_{g^{-1}(i)}(s\varphi')$; by equivariance, $\mu(\Gamma(g, s\varphi'), \hat{s}^a_{g^{-1}(i)}(s\varphi')) = \hat{s}^a_i(s\varphi)$; β_a is invariant. Hence $\mu(\varphi^{-1}\circ\varphi', \beta_a \hat{s}^a_{i'}(s\varphi')) = \beta_a \hat{s}^a_i(s\varphi)$, and applying $\mu(\varphi, \cdot)$ gives the claim.
4. *sc$^+$ on $\hat{V}_b$* Chapter14/TransportProof · SBLocalization.TransportInput.isScPlusSectionOn_tsec. Two cases at $y_0 \in \hat{V}_b$. (a) $y_0 = t(\varphi_0)$ for a morphism φ_0 with source in $\hat{V}_a$. Take a local sc-smooth inverse τ of t through φ_0 (Definition 7.1.4), and i with (i,j) a pair of $\hat{\tau}_{a,b}(\varphi_0)$ (the right leg of a representative is onto). For z near y_0: $\tau(z)$ goes from $\hat{V}_a$ to $\hat{V}_b$, and $\hat{\tau}_{a,b}(\tau(z)) = \hat{\tau}_{a,b}(\varphi_0)$ by local constancy, so $\tilde{s}^a_{b,j}(z) = \mu(\tau(z), \beta_a \hat{s}^a_i(s\tau(z)))$, the transport of an sc$^+$-section along an sc-smooth family of morphisms, which is sc$^+$ (Part XIII). (b) y_0 is not such a target. Then $y_0 \notin t(s^{-1}(K_a))$, $K_a = \mathrm{cl}\{y \in \tilde{U}(a) : \beta_a \neq 0\} \subset \hat{V}_a$, a closed set by the properness of $\mathrm{cl}\,\tilde{U}(a)$; on the open complement intersected with $\hat{V}_b$, every arc ending there starts at a point with $\beta_a = 0$, so the section is 0 near y_0.
5. *Equivariance* Chapter14/TransportProof · SBLocalization.TransportInput.tsec_equivariant: for $y \in \hat{V}_b$ and $g \in G_b$, append the step $\Gamma(g,y)$, with pair $(j, g(j))$ by *diag*, to an arc ending at (y,j); if there is none at (y,j), there is none at $(g*y, g(j))$ either (append $\Gamma(g^{-1}, g*y)$), and both values are zero.
6. *(4)* Chapter14/TransportProof · SBLocalization.TransportInput.tsec_compat: for $\varphi \in \hat{V}_{b,b'}$ and a pair (j,j') of $\hat{\tau}_{b,b'}(\varphi)$, append φ to an arc ending at $(s\varphi, j)$; if there is none, there is none at $(t\varphi, j')$ (append φ^{-1}, with the reversed pair by *swap*), and both sides are zero.
7. *(3)* Chapter14/TransportProof · SBLocalization.TransportInput.tsec_boundary: for $y \in \hat{V}_b \cap \partial X$. If an arc from (x,i), $x \in \hat{V}_a$, reaches (y,j), then $x \in \partial X$ (saturation), $\hat{s}^a_i(x) = s^{0a}_i(x)$ by Proposition 14.4.14 (1), and Definition 14.1.7 (4) along the arc (§XIV.16) gives $\mu(\varphi, s^{0a}_i(x)) = s^{0b}_j(y)$; with the

invariance of β_a, $\tilde{s}^a_{b,j}(y) = \beta_a(y) s^{0b}_j(y)$. If no arc reaches (y, j), then no morphism from $\widehat{V}_a$ reaches y (with any pair, as the right leg is onto), so $\beta_a(y) = 0$ by Lemma 14.5.1 (1), and both sides are zero.

8. *(1)*: for $y \in \widehat{V}_a$ the start arc $\mathrm{Arc}(a, a, i, i, 1_y)$ ends at (y, i), so $\tilde{s}^a_{a,i}(y) = \mu(1_y, \beta_a \hat{s}^a_i(y)) = \beta_a(y)\hat{s}^a_i(y)$; by step 3 every other arc ending at (y, i) gives the same value.
9. *(2)*: $\tilde{s}^a_{a,i}$ vanishes off $K_a \cap \widehat{V}_a$, by (1) and the definition of K_a, and K_a is closed in X and contained in $\widehat{V}_a$ by (14.53).

XIV.24 Theorem 14.5.5 (2017: Theorem 14.3): a structurability criterion

Theorem 14.5.5 (stronger) `Chapter14/StructurabilityCriterion · SBLocalization.theorem_14_5_5`, p. 678. *The data* `Chapter14/StructurabilityCriterion · SBLocalization.CriterionData`, indexed by a type with points $\mathrm{pt}(a)$: (a) neighbourhoods $U(a)$ with the natural G_a-action; (b) invariant open $V_a \subset U(a)$; (c) $\bigcup_a |V_a| = |X|$; (d) symmetric sc⁺-section structures $(s^a_i)_{i \in I_a}$ on V_a representing Λ; (e) correspondences $\tau_{a,a'}$ on $V(a, a') = \{\varphi : s\varphi \in V_a, t\varphi \in V_{a'}\}$. *Statement*: over an ep-groupoid with $|X|$ paracompact, an sc⁺-multisection functor Λ with such data is structurable. With a good system in place of paracompactness `Chapter14/StructurabilityCriterion · SBLocalization.theorem_14_5_5_of_goodSystem`; paracompactness gives one by Theorem 13.1.8 (Part XIII). *Stronger*: the text's (a) also asks t proper on $s^{-1}(\mathrm{cl}\, U(a))$, and (b) asks $\mathrm{cl}\,|V_a| \subset |U(a)|$; neither is used, so neither is assumed. *A reading*: "correspondence" in (e) is read as in Definitions 13.3.4 and 13.3.6 (Part XIII): locally constant with finitely many values, equivariant for the bi-actions, relating the sections pointwise on $V(a, a')$, with $\tau_{a,a}(\Gamma(g, y)) = [\mathrm{id}, g]$ and $\tau_{a',a}(\varphi) = \tau_{a,a'}(\varphi^{-1})^\sharp$; the text's proof uses the first of the last two for τ_{a_x,a_x}.

The text's proof restricts Λ to the full subcategory on $V = \bigcup V_a$, an equivalence by Theorem 13.4.3 (Part XIII), chooses a_x with $x \in V_{a_x}$ and small $Q(x) \subset V_{a_x}$, and restricts the data. *The Lean proof* does not pass through the restriction; it pulls the structures back along local transports, as in Theorem 13.5.3 (Part XIII).

1. *Local transports* `Chapter14/StructurabilityCriterion · SBLocalization.CriterionData.exists_transport`: every object y has an index a_y, an open $O(y) \ni y$ and an sc-smooth $\tau_y : O(y) \to$ morphisms with $t(\tau_y(z)) = z$ and $s(\tau_y(z)) \in V_{a_y}$. By (c), y is the target of a morphism φ_0 from some V_a; t is a local sc-diffeomorphism, and its local inverse through φ_0, restricted to where the source stays in the open V_a, is τ_y. With a good system $\mathcal{U}_0$ these data form the structure of the proof `Chapter14/StructurabilityCriterion · SBLocalization.CriterionData.nonempty_transport`.
2. *Conjugation.* Put $\sigma_y(z) = s(\tau_y(z)) \in V_{a_y}$. For ψ from $O(y)$ to $O(y')$, $\mathrm{conj}(\psi) = \tau_{y'}(t\psi)^{-1} \circ \psi \circ \tau_y(s\psi)$, a morphism from $\sigma_y(s\psi)$ to $\sigma_{y'}(t\psi)$, continuous in ψ and functorial: $\mathrm{conj}(\psi_1 \circ \psi_2) = \mathrm{conj}(\psi_1) \circ \mathrm{conj}(\psi_2)$, $\mathrm{conj}(1_z) = 1_{\sigma_y(z)}$, $\mathrm{conj}(\psi^{-1}) = \mathrm{conj}(\psi)^{-1}$.
3. *The homomorphisms* $\gamma_y : G_y \to G_{a_y}$. For ψ between points of $O(y)$ near the isotropy, $\mathrm{conj}(\psi)$ is a morphism between points of $V_{a_y} \subset U(a_y)$, hence $\Gamma(h, \sigma_y(s\psi))$ for a unique $h = H(\psi) \in G_{a_y}$, functorial in ψ. $\gamma_y(g) = H(\Gamma(g, y))$, with Γ the representation of $\mathcal{U}_0$, is a homomorphism. *The good system*: inside $\mathcal{U}_0(y) \cap O(y)$, a neighbourhood with the restricted natural action on which $\mathrm{conj}(\Gamma(g, z)) = \Gamma_{a_y}(\gamma_y(g), \sigma_y(z))$, so $\sigma_y(g * z) = \gamma_y(g) * \sigma_y(z)$ (this holds near y by continuity of H, which is locally constant).
4. *The structures.* At y: index set I_{a_y}, G_y acting through γ_y, and sections $s^y_i(z) = \mu(\tau_y(z), s^{a_y}_i(\sigma_y(z)))$, sc⁺ as transports along an sc-smooth family. They are symmetric, by step 3 and the symmetry of s^{a_y}, and represent Λ, because Λ is a functor and s^{a_y} represents it at $\sigma_y(z)$.

5. *The correspondences* $\bar{\tau}_{y,y'}(\varphi) = \tau_{a_y,a_{y'}}(\mathrm{conj}(\varphi))$: locally constant (conj continuous, τ locally constant), finitely many values, equivariant because conj of the bi-action is the bi-action of conj through γ_y, $\gamma_{y'}$, and the bi-action of correspondences pulls back along homomorphisms `Chapter14/StructurabilityCriterion · SBLocalization.IndexCorr.biact_compHom_gl`; they relate the sections, because a relation $s_j^{a'}(t\chi) = \mu(\chi, s_i^a(s\chi))$ for $\chi = \mathrm{conj}(\psi)$ transports to $s_j^{y'}(t\psi) = \mu(\psi, s_i^y(s\psi))$; the diagonal and swap conditions follow from those of τ.
6. *Conclusion* `Chapter14/StructurabilityCriterion · SBLocalization.CriterionData.Transport.isStructurable`: the decoration and the correspondences form a structured tuple (Definition 13.3.6), so Λ is structurable.

Use. The assembly applies the criterion to Λ' with the data built from the summed sections (§XIV.25).

XIV.25 The proof of Theorem 14.1.9 (2017: Theorem 14.2), pp. 656–678

The statement is in §XIV.7. The Lean proof `Chapter14/BoundaryExtensionTheorem · SBLocalization.theorem_14_1_9_charged_a6` has three lines: the data of §§14.3–14.5 exist (step A); they give, for every saturated open set containing the boundary domain support, a structurable extension with domain support inside it (step B); and the size control turns such extensions into one with $N(\Lambda') \le f$ (step C). This is the text's proof, §§14.2–14.5 and the end of p. 677.

Step A: the data exist (explicit) `Chapter14/AssemblyInputInstance · SBLocalization.exists_assemblyInput_a6`. *Statement*: for X tame with $|X|$ paracompact, sc-smooth partitions of unity on the objects, a tame strong bundle chart at every object, and Λ structurable over ∂X and charging every boundary fibre, there are data of §§14.3–14.5 for Λ (§XIV.22). *Proof.*

1. $\partial X = \emptyset$. The empty data `Chapter14/ExtensionAssembly · SBLocalization.emptyAssemblyInput`: $A = \emptyset$, $\beta \equiv 0$, zero sections; every condition is vacuous or about the empty boundary.
2. *A good representative.* Λ is the functor of a structured tuple (§XIV.5, structurability), and by Proposition 14.2.3 the tuple may be taken with (P4) (§XIV.8).
3. *The objects of §14.3* from (P4) and a boundary point (§XIV.13): (P5) neighbourhoods from the good system, the extension of the correspondences of Lemma 14.3.1, (P6) neighbourhoods, and the cover of Proposition 14.3.8.
4. *The cut-offs*: Theorem 7.5.7 (Part VII) gives sc-smooth partitions of unity on $|X|$ from those of the objects and paracompactness; Lemma 14.5.1 for the cover of ∂X by the $\widehat{V}_a$, with (14.53) (§XIV.21).
5. *The local extensions*: Proposition 14.4.14 for the objects of §14.3 (§XIV.20), one choice $\hat{s}^a$ for each $a \in A$ and zero for $a \notin A$ `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.shA6` `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.shA6_spec`.
6. *The input of Proposition 14.5.4* `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.transportInput_a6`: $\widetilde{U}(a)$, $\widehat{V}_a$ and $\hat{\tau}$ from the setting of §XIV.13, the boundary sections of the tuple, the properness of (P6), the local constancy of $\hat{\tau}$, the cut-offs of step 4 and the $\hat{s}^a$ of step 5. Lemma 14.5.1 (1) for these cut-offs is part of their specification.
7. *The data of §§14.3–14.5* `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.assemblyInput_a6`. The remaining fields: the values of $\hat{\tau}$ are finitely many (Proposition 14.3.4); the bi-action `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.biact_τ_a6`, from the equivariance of $\hat{\tau}$ in Proposition 14.3.4, through the identification of the bi-actions `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.biact_eq_a6`, since Γ and the natural action of the setting at $a \in \partial X$ are those of the tuple's good system `Chapter14/AssemblyInputInstance · SBLocalization.ZConcrete.Γ_eq_a6` `Chapter14/`

`AssemblyInputInstance · SBLocalization.ZConcrete.Φ_eq_a6` (the retraction of §XIV.13 is the identity there); the representation of Λ by the boundary sections and the functor property, from the tuple (Definition 14.1.3 (3)); and the non-empty index sets I_a, from charging (§XIV.2). *Explicit*: charging and the tame strong bundle charts are named.

Step B: the extension `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.extension`. *Statement*: for data of §§14.3–14.5, $|X|$ paracompact, sc-smooth partitions of unity, and a saturated open $\tilde{U}'$ containing the boundary domain support of Λ, there is a structurable Λ'' on W with dom-supp$(\Lambda'') \subset \tilde{U}'$ and $\Lambda'' = \Lambda$ over ∂X. *Proof.*

1. *The cut-off* `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.exists_cutoff`: an sc-smooth functor $\sigma : X \to [0,1]$ with $\sigma = 1$ on the boundary domain support and $\mathrm{cl}\{\sigma \neq 0\} \subset \tilde{U}'$. The boundary domain support is closed and saturated (§XIV.7), so its image K in $|X|$ is closed (§XIV.11), and $|\tilde{U}'|$ is open (Proposition 7.1.8). $|X|$ is paracompact Hausdorff, hence normal: choose an open u with $K \subset u$, $\mathrm{cl}\, u \subset |\tilde{U}'|$. The sc-smooth Urysohn lemma on the orbit space `Chapter7/PartitionsOfUnity · EpGroupoid.exists_isScSmoothMap_orbit_urysohn` (Theorem 7.5.7, Part VII) gives $F : |X| \to [0,1]$ sc-smooth, $F = 1$ on K, $F = 0$ off u; $\sigma = F \circ \pi$ is a functor, and its support lies in $\pi^{-1}(\mathrm{cl}\, u) \subset \tilde{U}'$, $\tilde{U}'$ being saturated.
2. *The functor* $\Lambda'' = \Lambda'_\sigma$ `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.mult`, with the cut-off folded into the sections (§XIV.22): for w with a morphism φ from $P(w)$ into some $\hat{V}_b$, $\Lambda''(w) = |I_b|^{-1}\#\{j : \sigma\tilde{s}^b_j(t\varphi) = \mu(\varphi, w)\}$; where there is no such φ, $\Lambda''(w) = 1$ if w is the zero of its fibre and 0 otherwise. *Independent of the chart* `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.mult_eq`: for two charts $\varphi : P(w) \to \hat{V}_b$, $\varphi' : P(w) \to \hat{V}_{b'}$, the morphism $\chi = \varphi' \circ \varphi^{-1}$ goes from $\hat{V}_b$ to $\hat{V}_{b'}$; the summed sections are compatible with $\hat{\tau}_{b,b'}(\chi)$ (§XIV.22), and a correspondence $[I_b \xleftarrow{\alpha} K \xrightarrow{\beta} I_{b'}]$ with bijective legs (Definition 13.3.1) matches the indices j with $\sigma\tilde{s}^b_j(t\varphi) = \mu(\varphi, w)$ to the indices j' with $\sigma\tilde{s}^{b'}_{j'}(t\varphi') = \mu(\varphi', w)$, and $|I_b| = |K| = |I_{b'}|$. Off C, Λ'' is the trivial functor (the sections vanish there). *A functor* `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.isWFunctor_mult`: a chart for w composed with ψ^{-1} is a chart for $\mu(\psi, w)$.
3. *Criterion data for* Λ'' `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.crit`, indexed by $A \sqcup X$. For $b \in A$: $\tilde{U}(b)$, $\hat{V}_b$, I_b, the sections $\sigma\tilde{s}^b_j$. For an object x: a natural neighbourhood of x and inside it the invariant set of its points off C `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.critV` (open, since C is closed, and invariant, since C is saturated), with one index and the zero section. The correspondences are the text's: $\hat{\tau}_{b,b'}$; $[I_b \leftarrow I_b \to \{1\}]$ from $\hat{V}_b$ to a set off C, where all $\sigma\tilde{s}^b_j$ vanish, so they all relate to the zero section; its reverse; and $[\{1\} \leftarrow \{1\} \to \{1\}]$. The covering condition (c): a point of C is isomorphic to a point of some $K_a \subset \hat{V}_a$, and a point x off C lies in its own set. The sections represent Λ'' on each set by the definition of Λ'' (resp. its triviality off C); the diagonal, swap and equivariance conditions for the correspondences involving $\{1\}$ are identities of correspondences with a one-point set.
4. Λ'' *is an sc⁺-multisection* `Chapter14/ExtensionAssembly · SBLocalization.CriterionData.hasLocalSectionStructure_t9`: criterion data with non-empty index sets for a functor give local section structures at every point, the structure of some set of the data transported by a local inverse of t (as in step 1 of Theorem 14.5.5, §XIV.24). The non-empty index sets are where charging enters: the weights $|I_b|^{-1}$ must sum to 1.
5. *Structurable* `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.isStructurable_mult`, by Theorem 14.5.5 (§XIV.24).
6. $\Lambda'' = \Lambda$ *over* ∂X `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.mult_boundary`, when $\sigma = 1$

on the boundary domain support. A boundary point y has a chart φ into some V_b, by Proposition 14.3.8 (3) and (2). There $\sigma\tilde{s}_j^b = \sigma s_j^{0b}$ by the sum identity (§XIV.22); the boundary sections vanish off the boundary domain support of Λ, so $\sigma s_j^{0b} = s_j^{0b}$ at all boundary points; and the count with the s_j^{0b} is $\Lambda(\mu(\varphi, w)) = \Lambda(w)$, by Definition 14.1.3 (3) and the functor property of Λ.

7. *The domain support* `Chapter14/ExtensionAssembly · SBLocalization.AssemblyInput.domSupp_mult_subset`: dom-supp$(\Lambda'') \subset \mathrm{cl}\{\sigma \neq 0\} \subset \tilde{U}'$, since where $\sigma = 0$ every section is zero and Λ'' is trivial.

How the assembly departs from the text. The text forms Λ' from the summed sections on the $\hat{V}_b$, gives the points $|x| \notin \bigcup |\hat{V}_b|$ a neighbourhood with the zero section, applies Theorem 14.5.5, and multiplies by the cut-off afterwards (Lemma 13.3.14). Here the cut-off σ, which only ensures the domain support lies in $\tilde{U}'$, is folded into the sections before Theorem 14.5.5 is applied, and the points off the closed set C (which contains every point where some section is non-zero) are covered by sets around all objects. The size control (step C) multiplies by a second cut-off afterwards, as the text does.

Step C: size control `Chapter14/BoundaryExtensionTheorem · SBLocalization.sizeControl_a6`, the end of p. 677. *Statement*: if for every saturated open $\tilde{U}' \supset$ the boundary domain support there is a structurable extension with domain support in $\tilde{U}'$, then, for N, $\tilde{U}$, f as in Theorem 14.1.9, there is a structurable Λ' with $N(\Lambda') \leq f$, dom-supp$(\Lambda') \subset \tilde{U}$, $\Lambda' = \Lambda$ over ∂X. *Tools*: the pointwise norm $N(\Lambda)(x) = \max\{N(w) : \Lambda(w) > 0, P(w) = x\}$ (Definition 13.2.3) is non-negative `Chapter14/NormControl · SBLocalization.pointwiseNorm_nonneg` and a functor `Chapter14/NormControl · SBLocalization.pointwiseNorm_tgt` ($\mu(\varphi, \cdot)$ is an isometry for an auxiliary norm and preserves Λ); on the domain of an sc⁺-section $y \mapsto N(s(y))$ is continuous `Chapter14/NormControl · SBLocalization.IsScPlusSectionOn.continuousOn_normW`, so $\{N(\Lambda) < f\}$ is open `Chapter14/NormControl · SBLocalization.isOpen_pointwiseNorm_lt` for continuous f, since on the domain of a local representation $N(\Lambda)(y) = \max_i N(s_i(y))$; $N(w) \leq |a| N(\Lambda)(P(w))$ on the support of $a\Lambda$ `Chapter14/NormControl · SBLocalization.normW_le_of_multisectionSmul_pos` (Definition 13.2.10), hence $N(\beta \odot \Lambda) \leq |\beta| N(\Lambda)$ `Chapter14/NormControl · SBLocalization.pointwiseNorm_smulFun_le` (Lemma 13.2.11); and $\beta \odot \Lambda = \Lambda$ where $\beta = 1$ `Chapter14/NormControl · SBLocalization.multisectionSmulFun_of_eq_one`. Saturation: ∂X is saturated `Chapter14/NormControl · SBLocalization.isSaturated_boundary_gl`, and closures `Chapter14/NormControl · SBLocalization.isSaturated_closure_gl` (saturations of open sets are open) and unions `Chapter14/NormControl · SBLocalization.isSaturated_union_gl` of saturated sets are saturated. The zero multisection has empty domain support `Chapter14/NormControl · SBLocalization.domSupp_zeroMultisection_gl`. *Proof.*

1. *A smaller target.* $U' = \{f > 0\}$ is open, saturated (f a functor), contains the boundary domain support (there $0 \leq N(\Lambda) < f$), and lies in $\tilde{U}$ (as $\mathrm{cl}\{f \neq 0\} \subset \tilde{U}$). Take the extension Λ'' with dom-supp$(\Lambda'') \subset U'$.
2. *The good set.* Put $h = N(\Lambda'')$ and $K =$ dom-supp$(\Lambda'') = \mathrm{cl}\{h > 0\}$ (Definition 13.2.14 through the norm); $h = 0$ off K. $G = \{h < f\} \cup (X \setminus K)$ is open and saturated (h, f functors; K the closure of a saturated set).
3. $\partial X \subset G$. Let $x \in \partial X \cap K$. Over x, Λ'' and Λ have the same support. If x is in the boundary domain support, $h(x) = N(\Lambda)(x) < f(x)$. If not, every w over x with $\Lambda(w) > 0$ is the zero (else x would be in the boundary domain support), so $h(x) = 0$; and $f(x) > 0$ because $x \in K \subset U'$. Either way $x \in \{h < f\}$.
4. *The cut-off.* $|\partial X|$ and $|X \setminus G|$ are closed (closed saturated sets, §XIV.11) and disjoint (by 3 and saturation). The sc-smooth Urysohn lemma `Chapter7/PartitionsOfUnity · EpGroupoid.exists_isScSmoothMap_orbit_urysohn` gives $F : |X| \to [0, 1]$ with $F = 1$ on $|\partial X|$ and $F = 0$ on $|X \setminus G|$; $\sigma = F \circ \pi$ is an sc-smooth functor.
5. $\Lambda' = \sigma \odot \Lambda''$ is structurable, by Lemma 13.3.14 (Part XIII) for functions.
6. *The bound.* $N(\Lambda') \leq \sigma h$. On $\{h < f\}$: $\sigma h \leq h < f$. On $X \setminus K$: $h = 0 \leq f$. Off G: $\sigma = 0 \leq f$.

7. *Domain support.* Where $N(\Lambda') > 0$, $\sigma h > 0$, so $h > 0$; hence dom-supp$(\Lambda') \subset \mathrm{cl}\{h > 0\} = K \subset U' \subset \tilde{U}$.
8. *Over* ∂X, $\sigma = 1$, so $\Lambda' = \Lambda'' = \Lambda$.

Readings in the size control, as in the statement (§XIV.7): the text uses $N(\Lambda)(x) < f(x)$ for $x \in \partial X$; the hypothesis gives it on the boundary domain support. At boundary points outside it where $f = 0$, the argument needs Λ'' trivial nearby; asking the extension to have domain support in $\{f > 0\}$ (step 1), which step B allows, provides this.

The chain, in the book's terms. §14.2: Proposition 14.2.3 (§XIV.8). §14.3: Lemma 14.3.1, Proposition 14.3.4, Lemmas 14.3.6, 14.3.7 and Proposition 14.3.8 (§§XIV.9–XIV.12). §14.4: the setting from §14.3, Lemma 14.4.5, Proposition 14.4.6, Lemmas 14.4.7, 14.4.9, Proposition 14.4.10, Definition 14.4.11 and Proposition 14.4.14 (§§XIV.13–XIV.20). §14.5: Lemma 14.5.1 with (14.53), the sum identity of Lemma 14.5.2, Proposition 14.5.4, Theorem 14.5.5, the assembly and the size control (§§XIV.21–XIV.25). No step assumes a hypothesis beyond the theorem's, read with the tame strong bundle charts and charging.

Remark on the superseded route. The size control and the assembly were first proved for the Lean statement of Theorem 14.1.9 without charging (§XIV.7). That route has four statements, kept in the formalization as properties of that statement. (i) The extension statement `Chapter14/NormControl · SBLocalization.theorem_14_1_9_extension_statement` (for every Λ structurable over ∂X and saturated open $\tilde{U}$ containing its boundary domain support, a structurable extension with domain support in $\tilde{U}$) implies that statement `Chapter14/NormControl · SBLocalization.theorem_14_1_9_hyp`, by the size control above for all Λ at once; it holds when $\partial X = \emptyset$ `Chapter14/NormControl · SBLocalization.theorem_14_1_9_extension_statement_of_boundary_eq_empty`. (ii) The hypothesis that every Λ structurable over ∂X has the data of §§14.3–14.5 `Chapter14/ExtensionAssembly · SBLocalization.AssemblyHyp` implies the extension statement `Chapter14/ExtensionAssembly · SBLocalization.theorem_14_1_9_extension_statement_of_assembly` and the uncharged statement `Chapter14/ExtensionAssembly · SBLocalization.theorem_14_1_9_of_assembly`, and holds when $\partial X = \emptyset$ `Chapter14/ExtensionAssembly · SBLocalization.assemblyHyp_of_boundary_eq_empty`. (iii) For X tame with $|X|$ paracompact and partitions of unity, that hypothesis holds only when $\partial X = \emptyset$ `Chapter14/BoundaryExtensionTheorem · SBLocalization.boundary_eq_empty_of_assemblyHyp_a6`, since it implies the uncharged statement, which does not hold when $\partial X \neq \emptyset$; step A is its form with charging. The proof above uses none of (i)–(iii).

XIV.26 A witness with boundary: the half-space bundle

The hypotheses of Theorem 14.1.9 are jointly satisfiable with $\partial X \neq \emptyset$, non-zero fibres and a non-trivial Λ; the theorem is applied to such data.

The object `Chapter14/HalfSpaceBundle · HalfSpaceBundle.halfSEP`: Part I's trivial strong bundle $H \times \mathbb{R}^k \to H$ over the half-space $H = [0,\infty) \times \mathbb{R}^m$, over the trivial ep-groupoid of H (objects H, only identity morphisms) `Chapter14/HalfSpaceBundle · HalfSpaceBundle.epBundleW1`. *The hypotheses of the theorem*: H is a tame quadrant, so the ep-groupoid is tame `Chapter14/HalfSpaceBundle · HalfSpaceBundle.isTame_halfSEP`; its orbit space, H itself, is metrizable, hence paracompact `Chapter14/HalfSpaceBundle · HalfSpaceBundle.hasParacompactOrbitSpace_halfSEP`; it admits sc-smooth partitions of unity `Chapter14/HalfSpaceBundle · HalfSpaceBundle.admitsScPartitionsOfUnity_halfSEP`, by Theorem 5.5.10 (Part V) with its one chart, whose model is finite-dimensional (Proposition 5.5.11); and Part I's re-centred charts are tame strong bundle charts at every object `Chapter14/HalfSpaceBundle · HalfSpaceBundle.hB_halfSEP`. *Non-degenerate*: $\partial H = \{x_1 = 0\}$ `Chapter14/HalfSpaceBundle · HalfSpaceBundle.mem_boundary_`

halfSEP_iff (degeneracy index 1 there), which contains 0 Chapter14/HalfSpaceBundle · HalfSpaceBundle.zero_mem_boundary_halfSEP; and the fibres $\mathbb{R}^k$ are non-zero for $k \geq 1$ Chapter14/HalfSpaceBundle · HalfSpaceBundle.nontrivial_fibre_halfSEP. All hypotheses hold jointly with the zero multisection, an auxiliary norm from Theorem 12.2.2 (Part XII), $\tilde{U} = X$ and $f \equiv 1$ Chapter14/HalfSpaceBundle · HalfSpaceBundle.theorem_14_1_9_charged_hypotheses_halfSEP, and the theorem applies Chapter14/HalfSpaceBundle · HalfSpaceBundle.theorem_14_1_9_halfSEP.

A non-trivial Λ. For $v \in \mathbb{R}^k$, $v \neq 0$, the constant section $x \mapsto (x, v)$ Chapter14/HalfSpaceConstSection · HalfSpaceBundle.constSec is sc⁺ Chapter14/HalfSpaceConstSection · HalfSpaceBundle.isScPlusSectionOn_constSec (constant in a finite-dimensional fibre). The function $\Lambda_v(w) = 1$ if $w = (P(w), v)$ and 0 otherwise Chapter14/HalfSpaceConstSection · HalfSpaceBundle.constMulti is structurable over ∂H Chapter14/HalfSpaceConstSection · HalfSpaceBundle.isBoundaryStructurable_constMulti: on a good system for ∂H, one index, the constant section Chapter14/HalfSpaceConstSection · HalfSpaceBundle.constStructure, and the trivial correspondence Chapter14/HalfSpaceConstSection · HalfSpaceBundle.constTau; Definition 14.1.3 (1) holds by the general lemma of §XIV.2 (an sc⁺-section on X is face-wise sc⁺ on every set). It charges ∂H Chapter14/HalfSpaceConstSection · HalfSpaceBundle.chargesBoundary_constMulti; its boundary domain support contains 0 Chapter14/HalfSpaceConstSection · HalfSpaceBundle.boundaryDomSupp_constMulti_nonempty, since $v \neq 0$; and $N(\Lambda_v)(x) = N(x, v)$ Chapter14/HalfSpaceConstSection · HalfSpaceBundle.pointwiseNorm_constMulti, a continuous function Chapter14/HalfSpaceConstSection · HalfSpaceBundle.continuous_normW_constSec. *The theorem applied* Chapter14/HalfSpaceConstSection · HalfSpaceBundle.theorem_14_1_9_constSec: with $\tilde{U} = X$ and $f(x) = N(x, v) + 1$ (a continuous functor, $> N(\Lambda_v)$ everywhere), there is a structurable Λ' on the bundle with $N(\Lambda')(x) \leq N(x, v) + 1$ and $\Lambda' = \Lambda_v$ over ∂H; every hypothesis is discharged.

Scope of the witness: the ep-groupoid has no isotropy and one chart, so it shows that the hypotheses are jointly satisfiable in a non-degenerate case, not that the isotropy part of the construction is exercised. The trivial bundle over $\mathbb{R}^n$, the witness of the tame strong bundle charts in §XIV.3, has $\partial X = \emptyset$ and so cannot serve here.

XIV.27 §14.6 and Definitions 14.6.1, 14.6.2 (2017: §14.6, Definitions 14.10, 14.11): structured sc⁺-multisections on the faces

§14.6, pp. 680–682, assumes X tame and face-structured. Each face F is saturated and a sub-M-polyfold, hence an ep-groupoid with the morphisms between its points. One is given a structured sc⁺-multisection on each $W|F$, compatible on the intersections of faces, and Theorem 14.6.3 glues them into one over ∂X, which then extends to W by Theorem 14.1.9. This subsection treats the preamble of p. 680 and the two definitions; the next one treats the theorem.

Faces. The faces of §14.6 are Part XI's ep-faces X_θ (Definition 11.1.3, Part XI): for a face θ of the orbit space, the set of objects whose orbit lies in θ. They are closed and saturated, and tame ep-groupoids with the morphisms between their points (Proposition 11.1.6, Part XI). The proof of Theorem 14.6.3 uses five properties of them near a boundary point, each proved separately.

1. *Faces consist of boundary points* Chapter14/FaceGerm · EpGroupoid.IsEpFace.subset_boundary. *Proof*: X_θ is the preimage of the closure of a component of $\{d = 1\}$ in $|X|$, and since the orbit map is open (Proposition 7.1.8, Part VII), the preimage of the closure is the closure of the preimage. Let y be in that closure and suppose $d(y) = 0$. Near y the degeneracy index is at most $d(y)$ (Lemma 2.4.3, Part II, upper semicontinuity), so a point y' of the component close to y has $1 = d(y') \leq d(y) = 0$,

which is impossible. Hence $d(y) \geq 1$.

2. *Every boundary point lies on a face* `Chapter14/FaceGerm · EpGroupoid.exists_isEpFace_mem`. *Proof*: face-structured means that $|x|$ lies on exactly $d_X(x)$ faces of $|X|$; for $x \in \partial X$ this number is at least 1, so the set of faces through $|x|$ is non-empty, and the ep-face of any of them contains x. *And on finitely many* `Chapter14/FaceGerm · EpGroupoid.finite_isEpFace_mem`: the faces of $|X|$ through $|x|$ number $d_X(x)$, and every ep-face through x is the image of one of them.
3. *Near x, every face through a point contains x* `Chapter14/FaceGerm · EpGroupoid.eventually_mem_of_isEpFace`. *Proof*: the degeneracy index of a tame M-polyfold is a corner index (Part II), so at x there are local pieces: an open $B \ni x$ such that each face of X through a point of B, read in B, is one of the $d(x)$ local pieces of $\{d = 1\}$ at x, each of which has x in its closure (Proposition 2.7.5 (3), Part II). For $y \in B$ and $X_\theta \ni y$, the unique face of the object M-polyfold through y inside X_θ is such a piece, so it contains x, and so does X_θ.
4. *Faces are saturated* `Chapter14/FaceAssembly · EpGroupoid.IsEpFace.tgt_mem_iff`: $s(\varphi) \in F$ iff $t(\varphi) \in F$, because $s(\varphi)$ and $t(\varphi)$ have the same orbit. Hence a face is invariant under every natural action at its points `Chapter14/FaceAssembly · EpGroupoid.IsEpFace.Φ_mem`: $\Phi(g)(y) = t(\Gamma(g, y))$ and $s(\Gamma(g, y)) = y$. This is the text's $g * (F \cap U(x)) = F \cap U(x)$.
5. *A local face of a tame chart lies in one face* `Chapter14/FaceGerm · EpGroupoid.exists_isEpFace_germ`: in a tame chart φ, if $t_i(\varphi(y)) = 0$, there are $\varepsilon > 0$ and a face X_θ such that every point e' of the retract within ε of $\varphi(y)$ with $t_i(e') = 0$ has $\varphi^{-1}(e') \in X_\theta$. *Proof*: by Part I's local face structure, there are ε and a point p of $\{d_O = 1\}$ such that, within ε, the face $\{t_i = 0\}$ of the retract lies in the closure of the component S of $\{d_O = 1\}$ through p. In a tame chart the degeneracy index of X is that of the model, so $\varphi^{-1}(S) \subset \{d_X = 1\}$; it is preconnected, as a continuous image of a preconnected set, and therefore lies in the component of $\{d_X = 1\}$ through $q = \varphi^{-1}(p)$. Let θ be the face of $|X|$ through $|q|$. A point e' as above lies in cl S, so $\varphi^{-1}(e')$ lies in the closure of $\varphi^{-1}(S)$, by continuity of φ^{-1} within S, hence in the face of the object M-polyfold through q, whose image in $|X|$ lies in θ.

A sixth fact concerns natural actions, not faces: *two natural representations of G_x agree near x* `Chapter14/FaceGerm · EpGroupoid.NaturalRep.eventually_Γ_eq`. For each g, $\Gamma(g, \cdot)$ and $\Gamma'(g, \cdot)$ are continuous with value g at x, so near x both lie in an open set around g on which s is injective; there $s(\Gamma(g, y)) = y = s(\Gamma'(g, y))$ gives $\Gamma(g, y) = \Gamma'(g, y)$. The natural actions agree as well `Chapter14/FaceGerm · EpGroupoid.NaturalRep.eventually_Φ_eq`. This is why the text can speak of "the" natural action on $F \cap U(x)$: it does not depend on $U(x)$ near x.

Sc⁺ relative to a face (restated) `Chapter14/FaceGerm · SBLocalization.IsFaceRelScPlusSectionOn`, p. 680. The text's sections of $W|F$ are sc⁺ for the induced M-polyfold structure of F. *As formalized*: s is a section over $U \subset F$ with values in $W_{0,1}$, and in every tame strong bundle chart, at every $y \in U$, on every local face germ $\{t_i = 0\}$ at $\varphi(y)$ that lies in F `Chapter14/FaceGerm · SBLocalization.FaceGermIn` (for some $\varepsilon > 0$, the points of the retract within ε of $\varphi(y)$ with $t_i = 0$ map into F), the local representative is sc⁺ on that germ in the sense of Part I. *Reading*: the local face germs lying in F are the local models of the sub-M-polyfold F at its points (Theorem 2.5.17, Part II; Proposition 11.1.6, Part XI), so this is "$s|F$ is an sc⁺-section of $W|F$" read in the charts of X, as Definition 14.1.3 (1) is read (§XIV.2); only the values of s on F near U enter. Definition 14.1.3 (1) implies it for every face `Chapter14/FaceGerm · SBLocalization.IsFaceScPlusSectionOn.isFaceRelScPlusSectionOn`, since it asks the same on every local face germ, whether in F or not; the property passes to subsets of U `Chapter14/FaceGerm · SBLocalization.IsFaceRelScPlusSectionOn.mono`. *Witness*: the zero section, on every $U \subset \partial X$ and for every face `Chapter14/FaceGerm · SBLocalization.isFaceRelScPlusSectionOn_fiberZero`.

Locality. Being sc⁺ on a face germ at a point depends only on the section near the point on the germ

Chapter14/FaceGerm · IsScPlusOnFaceNear.congr_nhds: if $s = s'$ on $O \cap N \cap \{t_i = 0\}$ for an open $N \ni x$, and s is sc⁺ on the germ $O \cap V \cap \{t_i = 0\}$, then s' is sc⁺ on $O \cap (V \cap N) \cap \{t_i = 0\}$: this set is an sc-retract, as an open subset of one (Proposition 2.3.1 (1), Part II), and s' agrees there with the restriction of s. The local representative of a section at z depends only on the section at $\varphi^{-1}(z)$ Chapter14/FaceGerm · SBLocalization.localRepOne_congr.

The gluing criterion Chapter14/FaceGerm · SBLocalization.isFaceScPlusSectionOn_of_local. *Statement*: let s be a section over U with values in $W_{0,1}$ such that for every $y \in U$ and every face $F \ni y$ there are a section σ, sc⁺ relative to F at y, and an open $N \ni y$ with $s = \sigma$ on $F \cap N$. Then s satisfies Definition 14.1.3 (1) on U. *Proof.* 1. Fix a tame strong bundle chart, $y \in U$ in its domain, and i with $t_i(\varphi(y)) = 0$. By fact 5, there are ε and a face F with the local face germ $\{t_i = 0\}$ at $\varphi(y)$, within ε, mapping into F; in particular $y \in F$ (take $e' = \varphi(y)$). 2. The hypothesis gives σ and N; since the germ lies in F, σ is sc⁺ on it at $\varphi(y)$. 3. The set of model points over N is $N' \cap O$ for an open N', by continuity of φ^{-1} on O. On $O \cap (N' \cap B_\varepsilon) \cap \{t_i = 0\}$, a point z has $\varphi^{-1}(z) \in F \cap N$, so $s(\varphi^{-1}(z)) = \sigma(\varphi^{-1}(z))$ and the local representatives agree at z. 4. Locality transfers sc⁺ from σ to s on the germ.

Structured data over a set Chapter14/FaceStructured · SBLocalization.RelTuple. For K a face or an intersection of faces, and an index family Chapter14/FaceStructured · SBLocalization.IndexFamily (finite sets I_x with G_x-actions, one for every object), the data of a structured sc⁺-multisection over K are:

- a function $\Lambda : W \to \mathbb{Q}^+$ that is a functor over K, $\Lambda(\mu(\varphi, w)) = \Lambda(w)$ for $s(\varphi) \in K$;
- for $x \in K$ a neighbourhood $U(x)$ with the natural G_x-action of X, with t proper on $s^{-1}(\mathrm{cl}(U(x) \cap K))$, condition (1) of Definition 13.1.4 (Part XIII) for the trace on K;
- sections s_i^x, $i \in I_x$, over $U(x) \cap K$, equivariant under the natural action, $s^x_{g(i)}(g * y) = \mu(\Gamma(g, y), s_i^x(y))$, and representing Λ on $U(x) \cap K$ by the counting formula of Definition 14.1.3 (3);
- correspondences $\tau_{x,x'}$ on the morphisms between $U(x) \cap K$ and $U(x') \cap K$, locally constant with finitely many values, with (a) inversion, (b) the diagonal, (c) the bi-action, and (4) the compatibility of the sections of Definition 14.1.7.

The regularity of the sections is not part of these data; it is added for faces below. The traces are written $U(x) \cap K$ Chapter14/FaceStructured · SBLocalization.RelTuple.U, and the morphism sets between them $\mathcal{U}(x, x')$ Chapter14/FaceStructured · SBLocalization.RelTuple.mor.

The equivalence Chapter14/FaceStructured · SBLocalization.RelTuple.Equiv, "similar to the X-case" (Definition 13.3.8, Part XIII), in the form of §XIV.5: $T \sim T'$ if $\Lambda = \Lambda'$ over K and there are open $O(x) \ni x$ with $O(x) \cap K \subset U(x) \cap U'(x)$, $I_x = I'_x$, and $\tau'_{x,x'} = \tau_{x,x'}$, transported along these equalities, on the morphisms between the $O(x) \cap K$. Reflexive Chapter14/FaceStructured · SBLocalization.RelTuple.Equiv.refl with $O(x) = U(x)$; symmetric Chapter14/FaceStructured · SBLocalization.RelTuple.Equiv.symm by reversing the equalities; transitive Chapter14/FaceStructured · SBLocalization.RelTuple.Equiv.trans with $O(x) = O_1(x) \cap O_2(x)$, a morphism between these sets being one for both pairs. The classes are the structured multisections over K Chapter14/FaceStructured · SBLocalization.RelStructured.

Reading: the text's "good neighbourhood $U_F(x) \subset F$" is read as it explains it on p. 680, $U(x) \cap F$ for a neighbourhood of X with the natural action and the properness of Definition 13.1.4 (1). Since F is closed, $\mathrm{cl}(U(x) \cap F)$ lies in F, and the properness in X is the properness inside the face (shown below).

Restriction to a smaller set Chapter14/FaceStructured · SBLocalization.RelTuple.restrictTo, for $K' \subset K$: the same Λ, index sets, sections and correspondences, on the traces $U(x) \cap K'$ for $x \in K'$ Chapter14/FaceStructured · SBLocalization.RelTuple.restrictTo_U. Properness passes to the smaller closed set;

the remaining conditions are inherited by subsets. Restriction respects the equivalence `Chapter14/FaceStructured · SBLocalization.RelTuple.Equiv.restrictTo`: the same open sets $O(x)$, for $x \in K'$, witness the equivalence of the restrictions, since $O(x) \cap K' \subset O(x) \cap K$. Restricting twice is restricting once `Chapter14/FaceStructured · SBLocalization.RelTuple.restrictTo_restrictTo_equiv`, by reflexivity, the two tuples being equal; this is the text's remark that $\tilde{\Lambda}_{F\cap F'\cap F''}$ can be formed for any number of faces. On classes `Chapter14/FaceStructured · SBLocalization.RelStructured.restrictTo`.

A structured sc⁺-multisection on $W|F$ `Chapter14/FaceStructured · SBLocalization.FaceStructuredTuple`, p. 680: data over a face F whose sections s_i^x are sc⁺ relative to F on $U(x) \cap F$. The equivalence is that of the underlying data `Chapter14/FaceStructured · SBLocalization.FaceStructuredTuple.setoid`, and the classes `Chapter14/FaceStructured · SBLocalization.FaceStructuredMultisection` are the text's $\tilde{\Lambda}_F = [\Lambda_F, \mathcal{U}_F, S_F, \tau_F]$. *Witness* `Chapter14/FaceStructured · SBLocalization.FaceStructuredTuple.zero`: the zero multisection on any face, on the index family $I_x = \{*\}$ with the trivial action `Chapter14/FaceStructured · SBLocalization.IndexFamily.unit`, with the zero section, the trivial correspondence $[\{*\} \leftarrow \{*\} \rightarrow \{*\}]$, and neighbourhoods with the properness property, which Part XIII supplies at every point.

Definition 14.6.1 (same) `Chapter14/FaceStructured · SBLocalization.FaceStructuredTuple.restrictFace`, p. 681: the restriction $\tilde{\Lambda}_F|F'$ to $W|(F \cap F')$ is the restriction of the data to $K' = F \cap F'$: it keeps Λ_F, the index sets, the sections and the correspondences, with neighbourhoods $U_F(x) \cap F \cap F'$ for $x \in F \cap F'$ and the correspondences restricted to the morphisms between them. Since restriction respects the equivalence, it is well defined on classes `Chapter14/FaceStructured · SBLocalization.FaceStructuredMultisection.restrictFace`, as the text's "obtained by taking a representative" asks. The text's $\tilde{\Lambda}_{F'}|F$, whose base is $F' \cap F$, is read as a class over $F \cap F'$ `Chapter14/FaceStructured · SBLocalization.FaceStructuredMultisection.restrictFace'`, the two sets being equal. The sections of the restriction are sc⁺ relative to F `Chapter14/FaceStructured · SBLocalization.FaceStructuredTuple.restrictFace_isFaceRelScPlus`, being restrictions of such sections.

Sc⁺ on the corner (same). The definition says that $\tilde{\Lambda}_F|F'$ is a structured sc⁺-multisection on $W|(F \cap F')$, so its sections must be sc⁺ on the corner $F \cap F'$, not only relative to F. *Locally* `Chapter14/CornerScPlus · IsScPlusOnCornerNear`: near x, for an open $V \ni x$, the corner germ $O \cap V \cap \{t_i = 0\} \cap \{t_j = 0\}$ is an sc-retract and s restricted to it is an sc⁺-section; the condition is symmetric in i and j `Chapter14/CornerScPlus · IsScPlusOnCornerNear.symm`, the two hyperplanes being intersected in either order. *From a face germ to a corner germ* `Chapter14/CornerScPlus · IsScPlusOnFaceNear.isScPlusOnCornerNear`: in a tame local model, sc⁺ on the face germ $\{t_i = 0\}$ at x gives sc⁺ on every corner germ $\{t_i = t_j = 0\}$ at x. *Proof*: by Part I's corner retraction for the pair $\{i, j\}$ of a tame retraction, the corner germ is an sc-retract; it is a subset of the face germ, and an sc-smooth map on a retract restricts to an sc-smooth map on a sub-retract of its source; the fibre condition of an sc⁺-section is pointwise. *On X* `Chapter14/CornerScPlus · SBLocalization.IsCornerRelScPlusSectionOn`: the sc⁺-sections of $W|(F \cap F')$, read in the tame strong bundle charts of X on the corner germs whose two face germs lie in F and in F'. Sc⁺ relative to F gives it `Chapter14/CornerScPlus · SBLocalization.IsFaceRelScPlusSectionOn.isCornerRelScPlusSectionOn`, by the local statement applied to the face germ in F (relative to F' it follows by the symmetry). The zero section has it `Chapter14/CornerScPlus · SBLocalization.isCornerRelScPlusSectionOn_fiberZero`. *Hence* `Chapter14/CornerScPlus · SBLocalization.FaceStructuredTuple.restrictFace_isCornerRelScPlus`: the sections of $\tilde{\Lambda}_F|F'$ are sc⁺ on the corner $F \cap F'$, and the restriction is a structured sc⁺-multisection on $W|(F \cap F')$ in the sense of the definition. This closes gap G.184.

The neighbourhoods $U_F(x)$ inside the face (restated, up to equivalence). The text asks the $U_F(x)$ to be good neighbourhoods for the ep-groupoid F, that is, the conditions of Definitions 13.1.2 and 13.1.4 inside F. Three steps.

1. *Conditions (1) and (3) of Definition 13.1.4 pass from X to a face.* Properness `Chapter14/FaceGoodSystem · EpGroupoid.isProperSubset_face`: if t is proper on $s^{-1}(\mathrm{cl}(U \cap X_\theta))$ in X, then it is proper on s^{-1} of the closure of the trace in the face ep-groupoid. The proof is by ultrafilters: an ultrafilter of face morphisms with sources in the closure and targets converging to $z \in X_\theta$ is an ultrafilter of morphisms of X with the same property, so it converges in X to some φ with $s(\varphi) \in \mathrm{cl}(U \cap X_\theta) \subset X_\theta$, the face being closed, and $t(\varphi) = z$; then φ is a face morphism, and the ultrafilter converges to it in the face. Components `Chapter14/FaceGoodSystem · EpGroupoid.isDiffeoComponent_face`: if every component of the morphisms between U and U' in X has s and t sc-diffeomorphisms onto open sets, so does every component of the face morphisms between $U \cap X_\theta$ and $U' \cap X_\theta$. A component C of the face morphism set is preconnected in X, so it lies in the component of X through any of its points; on that component s and t are injective, hence on C; and on an open set of morphisms of an ep-groupoid, injectivity of s and t is the component condition (the morphisms of the face form a sub-M-polyfold, with s, t local sc-diffeomorphisms). So every good system of X restricts to neighbourhoods of X_θ with (1) `Chapter14/FaceGoodSystem · EpGroupoid.GoodSystem.isProperSubset_face` and (3) `Chapter14/FaceGoodSystem · EpGroupoid.GoodSystem.isDiffeoComponent_face`.
2. *Shrinking a tuple.* For open $W(x) \ni x$, the invariant core of $U(x) \cap W(x)$ under the natural action is an open neighbourhood of x carrying the same action `Chapter14/FaceGoodSystem · EpGroupoid.NatNbhd.shrink`. Replacing the neighbourhoods of a tuple by these cores, and keeping Λ, the sections and the correspondences, gives a tuple `Chapter14/FaceGoodSystem · SBLocalization.RelTuple.shrink` equivalent to the original `Chapter14/FaceGoodSystem · SBLocalization.RelTuple.equiv_shrink`, with $O(x)$ the cores. Sections that were sc$^+$ relative to F stay so on the smaller sets `Chapter14/FaceGoodSystem · SBLocalization.FaceStructuredTuple.shrink`.
3. *Choosing the shrinking.* For $|X|$ paracompact, Theorem 13.1.8 (Part XIII) gives a good system $\mathcal{G}$ of X; shrinking inside its neighbourhoods $G(x)$ gives an equivalent tuple whose neighbourhoods satisfy (3) in X `Chapter14/FaceGoodSystem · SBLocalization.RelTuple.exists_equiv_isDiffeoComponent`, since (3) passes to smaller open sets (§XIV.4). By step 1, they satisfy (1) and (3) inside the face.

Conclusion `Chapter14/FaceGoodSystem · SBLocalization.FaceStructuredTuple.exists_equiv_faceGood`: for X tame and face-structured with $|X|$ paracompact, every face tuple over X_θ is equivalent to one with the same Λ, index sets, sections and correspondences whose $U_F(x)$ satisfy (1) and (3) inside the face ep-groupoid and are invariant under the natural G_x-action of X, $\Phi(g)(U(x) \cap F) \subset U(x) \cap F$. On classes `Chapter14/FaceGoodSystem · SBLocalization.FaceStructuredMultisection.exists_rep_faceGood`: every structured sc$^+$-multisection on $W|F$ has such a representative. *Restated*: the text takes good neighbourhoods inside F for every representative; the formalization shows that every class has a representative with them, which is all the gluing needs. *Not built*: condition (2) of Definition 13.1.4 inside the face, a natural representation of the ep-groupoid F itself with a connected domain inside F (Theorem 7.1.13, Part VII, for F). The natural action used is that of X restricted to $U(x) \cap F$, which is how the text describes it on p. 680. Nothing in §14.6 uses (2) (gap G.185, §XIV.29).

Definition 14.6.2 (same) `Chapter14/FaceStructured · SBLocalization.IsCompatibleAssignment`, p. 681: an assignment $F \mapsto \tilde{\Lambda}_F$, one structured sc$^+$-multisection on $W|F$ for each face, is compatible if $\tilde{\Lambda}_F|F' = \tilde{\Lambda}_{F'}|F$ as classes over $F \cap F'$ for all faces F, F'; the common class is the text's $\tilde{\Lambda}_{F\cap F'}$ `Chapter14/FaceStructured · SBLocalization.IsCompatibleAssignment.inter`. Equal classes have equivalent representatives `Chapter14/FaceStructured · SBLocalization.IsCompatibleAssignment.equiv`: the restrictions of the chosen representatives of $\tilde{\Lambda}_F$ and $\tilde{\Lambda}_{F'}$ to $F \cap F'$ are equivalent. The text draws two consequences, both proved from this: "$I_x^F = I_x^{F'}$" for $x \in F \cap F'$ `Chapter14/FaceStructured · SBLocalization.IsCompatibleAssignment.`

`index_eq`, since equivalent tuples have equal index sets; and $\Lambda_F = \Lambda_{F'}$ on $W|(F \cap F')$ `Chapter14/FaceStructured · SBLocalization.IsCompatibleAssignment.Λ_eq`, since equivalent tuples have equal functors. What the equivalence does not give, the equality of the sections, is the subject of the next subsection. *Witness* `Chapter14/FaceStructured · SBLocalization.isCompatibleAssignment_zero`: the zero multisection on every face, on any choice of neighbourhoods; all restrictions are the zero data over $F \cap F'$, equivalent with $O(x)$ the intersections of the two neighbourhoods.

XIV.28 Theorem 14.6.3 (2017: Theorem 14.4): gluing the faces, and the extension

Theorem 14.6.3 (narrower) `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.theorem_14_6_3_hyp`, p. 682. *Input* `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData`, the chosen representatives of the text's proof:

- one index family I_x, the text's "$I_x := I_x^F$";
- for every face F a face tuple $(\Lambda_F, \mathcal{U}_F, S_F, \tau_F)$ on this index family;
- $\Lambda_F = \Lambda_{F'}$ on $W|(F \cap F')$;
- $s^x_{F,i} = s^x_{F',i}$ on $U_F(x) \cap U_{F'}(x) \cap F \cap F'$, for $x \in F \cap F'$;
- $\tau_{F,x,x'} = \tau_{F',x,x'}$ on the morphisms between the sets $U_F(x) \cap U_{F'}(x) \cap F \cap F'$ and $U_F(x') \cap U_{F'}(x') \cap F \cap F'$.

Such data form a compatible assignment `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.isCompatibleAssignment`: the restrictions of the two tuples to $F \cap F'$ are equivalent, with $O(x) = U_F(x) \cap U_{F'}(x)$, equal index sets, and equal correspondences on the morphisms between these sets. *Statement*: for X tame and face-structured with $|X|$ paracompact, the glued function $\Lambda(w) = \Lambda_F(w)$ for $P(w) \in F$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.Λg` is structurable over ∂X and equals Λ_F over each face F `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.Λg_eq`; its structure restricts to the given ones.

Narrower: the input is representatives that agree, not a compatible assignment of classes. The text says that the compatibility gives $s^x_{F,i} = s^x_{F',i}$ on $U_F(x) \cap U_{F'}(x)$. As we read Definition 14.6.2, this does not follow: the equivalence of Definition 13.3.8, and its analogue here, compares Λ, the index sets and the correspondences on smaller neighbourhoods, not the sections, so two equivalent tuples may have different sections at the same index. *An illustration* (not formalized): on a face with trivial isotropy along which the only morphisms are identities, take $I_x = \{1, 2\}$ at every point, sections s^x_1, s^x_2 that agree across the neighbourhoods but $s_1 \neq s_2$, and correspondences that pair each index with itself. Exchanging s^x_1 and s^x_2 at every x gives a tuple with the same Λ (the counting formula is symmetric in the indices), the same index sets, and the same correspondences, which still satisfy (4), since the pair (i, i) now relates the exchanged sections, which again agree. The two tuples are equivalent, and their sections at the index 1 differ. Over one face such a difference can be undone by relabelling; the text's step asks that it can be undone on all faces through x at once, consistently with the correspondences. Presumably the text means that representatives can be chosen so that they agree; we neither prove this nor claim the contrary. The two routes to the class-level statement are gap G.173 (§XIV.29).

Proof, the text's, as the Lean proof goes.

1. *The glued functor.* $\Lambda(w) = \Lambda_F(w)$ for any face $F \ni P(w)$, and 0 off ∂X. It is well defined by the agreement of the Λ_F on $F \cap F'$, and defined on all of $W|\partial X$ because every boundary point lies

on a face (fact 2 of §XIV.27). It is a functor over ∂X: for $s(\varphi) \in F$, also $t(\varphi) \in F$ (fact 4), and Λ_F is a functor over F.

2. *A face selection.* For $x \in \partial X$ and objects y, x', choose a face through y, x and x' if there is one, and otherwise any face through x `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.faceSel`; when one exists, the chosen face contains all three `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.faceSel_spec`. The glued sections and correspondences are read from the selected face: $s_i^x(y) = s_{F,i}^x(y)$ with F selected for (x, y, x) `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.sg`, and $\tau_{x,x'}(\varphi) = \tau_{F,x,x'}(\varphi)$ with F selected for $(x, s(\varphi), x')$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.τg`. That the choice does not matter is proved in step 4.
3. *An adapted good system* `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.exists_adapted`, the text's choice of $V(x)$ with $U(x) \cap F \subset U_F(x)$. A good system $\mathcal{W}$ for ∂X is *adapted* `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.Adapted` if for every $x \in \partial X$ and $y \in U(x)$: every face through y contains x; and for every face $F \ni x$, $y \in U_F(x)$ and $\Gamma(g, y) = \Gamma_F(g, y)$ for all $g \in G_x$. *Construction*: (a) a good system $\mathcal{U}_0$ for ∂X from Theorem 14.1.6 (§XIV.4); (b) at each x, an open $O(x) \ni x$ on which every face through a point contains x (fact 3); (c) at each x, a neighbourhood $M(x) \subset O(x)$ with the natural action, below $U_0(x)$ and below each of the finitely many $U_F(x)$, $F \ni x$ (fact 2), with the restricted actions: the common refinement of finitely many natural neighbourhoods of x (Part XIII); (d) a refinement of $\mathcal{U}_0$ inside the $M(x)$ (§XIV.4). The natural action on $V(x)$ is that of $U_0(x)$, which on $M(x)$ is that of $M(x)$, which is that of each $U_F(x)$. Two consequences: on $U(x)$ the natural actions of $V(x)$ and $V_F(x)$ agree `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.Φ_eq`, as targets of the same morphisms $\Gamma(g, y)$; and $U(x) \cap F \subset U_F(x)$ for the faces $F \ni x$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.glue_U_inter_subset`.
4. *The glued data agree with the face data.* On $U(x) \cap F$, $s_i^x = s_{F,i}^x$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.sg_eq`: for $y \in U(x) \cap F$, F contains x (adapted), so a face through y and x exists and the selected face G contains both; $y \in U_G(x) \cap U_F(x) \cap G \cap F$ (adapted), where $s_{G,i}^x = s_{F,i}^x$ by the input. A morphism φ between $U(x)$ and $U(x')$ with source on F is one between $U_F(x) \cap F$ and $U_F(x') \cap F$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.mem_mor_face`: $t(\varphi) \in F$ (saturation), $x, x' \in F$ (adapted), and the traces lie in U_F (adapted). Hence on such morphisms $\tau_{x,x'} = \tau_{F,x,x'}$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.τg_eq`, by the input's agreement of the correspondences for the selected face and F.
5. *The symmetric structure on $U(x)$* `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.S`, with index set I_x and sections s_i^x.
   - *Face-wise sc⁺* (Definition 14.1.3 (1)), by the gluing criterion of §XIV.27: the values lie in $W_{0,1}$ because at y, on a face $F \ni y$, $s_i^x(y) = s_{F,i}^x(y)$, which is sc⁺ relative to F; and near y, on each face $F \ni y$, s_i^x agrees on $F \cap U(x)$ with $s_{F,i}^x$, which is sc⁺ relative to F at y.
   - *Equivariant*: for $y \in U(x)$ on a face F, also $g * y \in F$ (fact 4); both sides are read in F by step 4, the natural actions of $V(x)$ and $V_F(x)$ agree there by step 3, and S_F is equivariant.
   - *Represents* Λ: for $P(w) \in U(x) \cap F$, $\Lambda(w) = \Lambda_F(w)$, which is $|I_x|^{-1}$ times the number of i with $s_{F,i}^x(P(w)) = w$, the same as the number with $s_i^x(P(w)) = w$ by step 4.

   So the glued Λ is an sc⁺-multisection over ∂X `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.isBoundaryScPlusMultisection`, with the decoration $(\mathcal{W}, S)$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.dec`.
6. *The correspondences* `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.tau`, $\tau_{x,x'}(\varphi) = \tau_{F,x,x'}(\varphi)$ for $s(\varphi) \in F$.
   - *Locally constant*. Near φ, every face through the source of a nearby morphism contains $s(\varphi)$ (fact 3, pulled back by the continuous s). For each of the finitely many faces $F \ni s(\varphi)$, τ_F

is locally constant at φ. Intersecting these finitely many neighbourhoods, a nearby ψ in the morphism set has its source on some face G, which contains $s(\varphi)$, and $\tau(\psi) = \tau_G(\psi) = \tau_G(\varphi) = \tau(\varphi)$ by step 4.

- *Finitely many values*: every value is a value of some τ_F with F through x and x', a finite union of finite sets.
- *(a) Inversion*: $s(\varphi^{-1}) = t(\varphi) \in F$; read both sides in F.
- *(b) The diagonal*: $\Gamma(g, z)$ has source z; for z on F, $\Gamma(g, z) = \Gamma_F(g, z)$ by step 3, and τ_F has (b).
- *(c) The bi-action*: the source of $g' * \varphi * g$ is $\Phi(g^{-1})(s(\varphi))$, on F by fact 4. The bi-action computed with the natural actions of $V(x)$, $V(x')$ equals that computed with those of $V_F(x)$, $V_F(x')$, by step 3; then τ_F has (c).
- *(4) Compatibility*: read in the face of $s(\varphi)$, with $s_j^{x'}(t(\varphi)) = s_{F,j}^{x'}(t(\varphi))$ and $s_i^x(s(\varphi)) = s_{F,i}^x(s(\varphi))$ by step 4.

7. *The structured tuple* `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.glue`: $(\Lambda, \mathcal{W}, S, \tau)$, so Λ is structurable over ∂X. It restricts to the face data: $s_i^x = s_{F,i}^x$ on $U(x) \cap F$ `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.glue_s`, and $\tau_{x,x'} = \tau_{F,x,x'}$ on the morphisms of $\mathcal{U}(x, x')$ with source on F `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.glue_τ`.

Witness `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.zero`: the zero multisection on every face, on the index family $I_x = \{*\}$; all agreements are equalities of zero data, and the glued Λ is the zero multisection over ∂X `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.zero_Λg`. It charges every boundary fibre (the zero vector has weight 1), so it also satisfies the charging hypothesis of the extension part below. The witness is degenerate in the sections, all zero, but not in the boundary: tame face-structured ep-groupoids with $|X|$ paracompact and $\partial X \neq \emptyset$ exist (Part XI).

The extension part (narrower) `Chapter14/BoundaryExtensionTheorem · SBLocalization.CompatibleFaceData.theorem_14_6_3_extension_a6`. *Statement*: let X be face-structured (hence tame) with $|X|$ paracompact, with sc-smooth partitions of unity on the object M-polyfold and a tame strong bundle chart at every object, and let face data with agreeing representatives be given whose glued Λ charges every boundary fibre. For N, $\tilde{U}$, f as in Theorem 14.1.9 (with the boundary domain support of the glued Λ), there is a structurable Λ' on W with $N(\Lambda') \leq f$, dom-supp$(\Lambda') \subset \tilde{U}$, and $\Lambda' = \Lambda_F$ over every face F. *Proof*: 1. The glued Λ is structurable over ∂X (above). 2. Theorem 14.1.9 with charging (§XIV.7, proved in §XIV.25) gives Λ' with the size and support properties and $\Lambda' = \Lambda$ over ∂X. 3. For $P(w) \in F$, $P(w) \in \partial X$ (fact 1), so $\Lambda'(w) = \Lambda(w) = \Lambda_F(w)$. *Narrower*: the agreeing representatives, and the two readings of Theorem 14.1.9 (§XIV.7). Charging is necessary here too, since the conclusion makes Λ the restriction of a structurable functor (§XIV.7).

Remark: the form with the uncharged statement. A form taking the uncharged Lean statement of Theorem 14.1.9 as a hypothesis `Chapter14/FaceAssembly · SBLocalization.CompatibleFaceData.theorem_14_6_3_extension_hyp` remains in the formalization, with the same proof. That hypothesis holds only when $\partial X = \emptyset$ (§XIV.7), in which case there are no faces and the statement says nothing; the form above does not use it.

XIV.29 What is not formalized

Every numbered statement of Chapter 14 is formalized, either as printed or in a form recorded in its subsection. What remains open is listed here by gap number, with what is missing and an estimate in lines of Lean. None of the open gaps lies on the path of Theorem 14.1.9: the theorem, with its two readings, is proved from the construction of §§14.2–14.5, and its extension part over the faces from Theorem 14.6.3

for agreeing representatives.

- **Gap G.172**, the multisection form of Lemma 14.5.2 (formalized in part, §XIV.22). *Formalized*: the identity for the summed sections, $\sum_a \tilde{s}^a_{b,j} = s^{0b}_j$ over ∂X, which is the only use the proof of Theorem 14.1.9 makes of the lemma. *Missing*: that the structured functors $\Lambda_a = (\beta_a|\partial X) \odot \Lambda$ form a commensurable, locally finite family over ∂X whose sum is Λ. This is a boundary version of the commensurable sums of Part XIII (Definitions 13.3.11 and 13.4.5): the index sets and correspondences of Λ would be carried to each Λ_a, the commensurability checked on the common good system of §XIV.21, and the sum computed fibrewise from the section identity. About 120 lines. Nothing formalized uses it. Remark 14.5.3, which explains the lemma, is prose.
- **Gap G.173**, Theorem 14.6.3 from a class-level compatible assignment (§XIV.28). *Formalized*: faces as Part XI's ep-faces with their local properties; sc$^+$ relative to a face and on a corner; Definitions 14.6.1 and 14.6.2, with the two consequences the text draws; good systems on a face up to equivalence; Theorem 14.6.3 for face data whose chosen representatives agree on the intersections of faces; and its extension part, from Theorem 14.1.9 with charging. *Missing*: the passage from a compatible assignment of classes, $\tilde{\Lambda}_F|F' = \tilde{\Lambda}_{F'}|F$, to representatives that agree. The equivalence of structured multisections on a face compares Λ, the index sets and the correspondences on smaller neighbourhoods, not the sections, so two routes are open. (a) *A re-choice of representatives*: near each $x \in \partial X$, relabellings $I^{F'}_x \to I^F_x$ compatible with the correspondences and with the G_x-action, carrying the sections of F' to those of F on $F \cap F'$, chosen consistently over the finitely many faces through x (at a corner of index d the d relabellings must commute) and locally constant in x; possibly with a hypothesis on the local constancy of the relabelling where two sections cross. About 350–550 lines. (b) *An example*: two equivalent representatives over a corner whose sections differ by an index swap, such that no re-choice agrees on two faces at once, which would show that the text's step needs the agreeing representatives as an assumption. About 150–250 lines. We do not know which of the two holds.
- **Gap G.185**, condition (2) of a good system on a face (formalized in part, §XIV.27). *Formalized*: every structured sc$^+$-multisection on $W|F$ has a representative whose neighbourhoods $U_F(x)$ satisfy (1), the properness of t over the closure, and (3), the component condition, inside the face ep-groupoid, and are invariant under the natural action of X restricted to $U(x) \cap F$. *Missing*: condition (2) of Definition 13.1.4 in the strict sense, a natural representation of the ep-groupoid F itself with a connected domain inside F (Theorem 7.1.13, Part VII, applied to F), and its identification with the restricted action of X near x. About 150–250 lines. Nothing in §14.6 uses it: the gluing of Theorem 14.6.3 reads the neighbourhoods $U_F(x)$ as $U(x) \cap F$, as the text explains them on p. 680.
- **Gap G.186**, the readings of the standing hypotheses of Theorem 14.1.9 (§§XIV.3, XIV.7, XIV.26). (a) *Non-empty index sets in the formal Definition 14.1.3.* The theorem is stated with charging, which for a structured Λ is the same as $I_x \neq \emptyset$ at every boundary point, and which is necessary. Building $I_x \neq \emptyset$ into the definition itself is an edit of an existing definition, with about 20–60 lines of follow-up where structures with empty index sets serve as witnesses; charging would then follow from structurability. (b) *A witness with $\partial X \neq \emptyset$* in which all hypotheses of the theorem hold jointly, tame strong bundle charts included: done, the half-space bundle with a constant non-zero section (§XIV.26). (c) *The tame strong bundle charts at every object derived from the tameness of X*, if that holds: a strong bundle over a tame ep-groupoid would be shown to have, at every object, a strong bundle chart whose base retraction is tame, by Part I's construction of tame retractions applied to the base of a strong bundle retraction and lifted to the bundle. About 300–600 lines.
- **Lemma 14.4.13 (2) at every point of** $\mathrm{cl}_X(\widehat{V}_a) \cap \partial X$ (§XIV.19). Proved for points of $\mathrm{cl}_X(V_a)$, which

is what Proposition 14.4.14 uses. The printed range would need a coherent system with (4) at the other points, which the stronger Lemma 14.4.9 (3) of §XIV.17 permits. About 90 lines; not needed.

- **Prose.** Remarks 14.1.10, 14.3.5, 14.4.1, 14.4.12 and 14.5.3 are explanatory and have nothing to formalize beyond what their subsections record.

Closed gaps, for reference: G.164, Proposition 14.1.8 over ∂X (§XIV.6); G.165, the faces $\bar{\theta}_j$ as tame M-polyfolds (§XIV.1); G.168, Proposition 14.4.6 (2) in general (§XIV.16); G.169, the setting of §14.4 from the objects of §14.3 (§XIV.13); G.170, the proof of Proposition 14.5.4 (§XIV.23); G.171, the data of §§14.3–14.5 for every charging Λ (§XIV.25); G.184, sc$^+$ on the corners $F \cap F'$ (§XIV.27).

XIV.30 What the formalization taught us

No statement of Chapter 14 was found not to hold as we read it. Two statements are proved with readings that are hypotheses of their Lean form (Theorem 14.1.9: tame strong bundle charts and charging; Theorem 14.6.3: agreeing representatives), and one has a printed range wider than its proof covers (Lemma 14.4.13 (2)). The rest is proved as printed, or in a stronger form.

Two kinds of formal content. Chapter 14 is the longest construction of the book, and what it needs splits in two.

The first kind is *local topology of the morphism space*: shrinking good neighbourhoods so that closures stay inside (Lemma 14.2.1, §XIV.8), separating the values of a locally constant correspondence by open sets (Lemma 14.3.1, §XIV.9), extending it by components (Proposition 14.3.4, §XIV.10), and choosing neighbourhoods compatible with the action and with local finiteness (Lemmas 14.3.6, 14.3.7, Proposition 14.4.10, §§XIV.11, XIV.18). All of it rests on three facts used again and again. First, t is proper on s^{-1} of the closure of a good neighbourhood, so a property of the morphisms from a point persists near it. Second, s and t are local homeomorphisms on sheets, so the sheet through a morphism is locally constant. Third, a locally constant function on an open set is constant on its components. The diagonal property of Proposition 14.3.4, for which the text gives no argument, is the second fact applied through sheet labels: the component of $\Gamma(g, y)$ stays in the sheet of g and reaches the boundary there (§XIV.10). The inversion symmetry of the extended correspondences, which the text does not state, costs one more intersection in Lemma 14.3.1 and is what the z-loops of §14.4 need to be reversible (§§XIV.9, XIV.14).

The second kind is *combinatorics of index sets along chains of morphisms*. Encoding a z-loop together with its arc as one inductive predicate, built by appending one morphism and one index step at a time, made the equivalence-relation properties of $\sim_z$, which the text asserts, and Lemma 14.4.5 short (§XIV.14). It made Proposition 14.4.6 (1) a deformation of the chain along sheets, one morphism at a time, without Lemma 14.4.7 (§XIV.15). It carried the limit argument of Proposition 14.4.6 (2): with Lemma 14.4.7 around the finitely many isomorphs of the limit point, each step of a nearby loop moves along its own sheet to the boundary, so the text's limit loop need not be built, and the result holds for loops at points of $\hat{V}_a$, the form Lemma 14.4.9 (3) uses (§XIV.16). It also carried Proposition 14.5.4: defining the transported section through chains rather than single morphisms gives its equivariance and its compatibility with $\hat{\tau}$ directly, and its well-definedness is the text's closing of two chains into a loop (§XIV.23).

Steps that needed less than printed.

- *Theorem 14.5.5* needs neither its properness nor its closure condition: local transports into the sets V_a and the conjugation homomorphisms of Theorem 13.5.3 (Part XIII) carry the structure (§XIV.24).

- *Lemma 14.5.1* does not use tameness, and (14.53) holds for the cover of §14.3 itself, without the shrinking the text performs: a morphism from an invariant subset of a natural neighbourhood to a point of its closure ends in that subset, because the isotropy group is finite and the morphism space Hausdorff (§XIV.21).
- *Lemma 14.5.2* enters the proof of Theorem 14.1.9 only through its identity for the summed sections; the commensurable family over ∂X is not needed (§XIV.22, gap G.172).
- *Proposition 14.1.8* holds along generalized strong bundle isomorphisms and their classes without the paracompactness of the orbit spaces (§XIV.6).
- *Definition 14.4.11 (2)* is not needed once Proposition 14.4.14 is proved by averaging (§§XIV.18, XIV.20).
- *Proposition 14.4.6 (1)* does not need Lemma 14.4.7 (§XIV.15).

Steps that needed more, or a different argument.

- *Proposition 14.1.4.* The local extension cannot be glued with one partition of unity of X, because the boundary data on an open $V(x)$ may be unbounded near its frontier. An exhaustion of $V(x)$ by the sets at distance $> 1/n$ from its complement, glued by sc-smooth cut-offs, does it (§XIV.3).
- *Averaging.* Averaging over the whole isotropy group, $\bar{s}_j(y) = |G_x|^{-1} \sum_g \mu(\Gamma(g^{-1}, g*y), s_{g(j)}(g*y))$, replaces the text's average over a stabilizer together with transport along an orbit, both in Proposition 14.1.4 and in Proposition 14.4.14. In Proposition 14.4.14 it also replaces the class-by-class, orbit-by-orbit construction with an invariant partition of unity (§§XIV.3, XIV.20).
- *Theorem 14.1.6* is proved from tameness of X and paracompactness of $|X|$, which its proof uses, in place of the paracompactness of $|\partial X|$ printed in the statement (§XIV.4).
- *The size control of Theorem 14.1.9* hides one choice: the extension must be taken with support in $\{f > 0\}$, not merely in $\tilde{U}$, or the cut-off cannot reach the boundary points where $f = 0$; and the inequality $N(\Lambda) < f$ is needed, and assumed, on the boundary domain support rather than on all of ∂X (§§XIV.7, XIV.25).
- *Proposition 14.5.4* needs one property of the cut-offs that its statement does not list, that β_a vanishes off the saturation of $\hat{V}_a$; Lemma 14.5.1 (1) gives it (§XIV.23).
- *Index sets on two domains.* The index sets of §14.1 live on boundary points and those of §14.4 on all objects; a map to boundary points that is the identity on ∂X, with the identity on morphisms as a homomorphism of isotropy groups, joins them (§XIV.13).
- *Proposition 14.1.8 over ∂X* carries everything along except Definition 14.1.3 (1), which is read in every tame strong bundle chart; its transport needs that tame charts compose with local strong bundle isomorphisms, a fact Part I proved for Theorem 3.6.8 (§XIV.6).
- *Sc⁺ on corners.* The restriction of Definition 14.6.1 is sc⁺ on the corner $F \cap F'$ because, in a tame model, the corner germ $\{t_i = t_j = 0\}$ is itself an sc-retract by Part I's corner retraction, and an sc⁺ map on a face germ restricts to it (§XIV.27).

Readings. Each is recorded in its subsection; together:

- Lemma 14.2.2: the morphism sets $\mathcal{U}(x, x')$ are read with $t(\varphi) \in U(x')$, as in (P3), where the text prints $U(x)$ (§XIV.8).
- Definition 14.4.8: the last index of an $\approx_z$-chain is i_k (§XIV.17).
- Proposition 14.4.6 (2): the loops are taken at points $z_k \in \hat{V}_a$ (§XIV.16).
- Definition 14.4.11 (3): read for the closure, as Lemma 14.4.9 provides it (§XIV.18).
- Lemma 14.4.13 (2): stated for $z \in \mathrm{cl}_X(V_a)$, the range Definition 14.4.11 (4) covers and Proposition 14.4.14 uses (§XIV.19).

- Definition 14.1.3 (1): "$s|\bar{\theta}_j$ is sc$^+$" read through the tame strong bundle charts of X, on every local face germ (§XIV.2); likewise sc$^+$ relative to a face and on a corner (§XIV.27).
- Theorem 14.1.9: "a strong bundle over a tame ep-groupoid" read as tame strong bundle charts at every object; the factor $|I_x|^{-1}$ read as charging; "supported in $\tilde{U}$" read as $\mathrm{cl}\{f \neq 0\} \subset \tilde{U}$ (§XIV.7).
- §14.6: "good neighbourhood $U_F(x) \subset F$" read as $U(x) \cap F$ with the restricted natural action (§XIV.27); Theorem 14.6.3 read with representatives that agree on $F \cap F'$ (§XIV.28).

A property of our own formalization. Definition 14.1.3 (3) writes $\Lambda(w) = |I_x|^{-1} \cdot \#\{i : s_i^x(P(w)) = w\}$, which presumes $I_x \neq \emptyset$. The formal definition does not ask for it, so the zero function, with empty index sets, counts as structurable over ∂X, and no structurable extension can vanish over a boundary fibre. A Lean statement of Theorem 14.1.9 without the charging condition, and every hypothesis that asks for its conclusion for all Λ, therefore holds only when $\partial X = \emptyset$ (§XIV.7); witnesses on spaces without boundary cannot reveal this, since every condition on ∂X is then vacuous. Two lessons follow for the formalization rather than for the text. A witness on a space without boundary says nothing about a statement on ∂X; the half-space bundle (§XIV.26) is the witness that does. And a statement about structurable functors should be checked against the zero function with empty index sets, which the formal definitions admit and the printed formulas exclude. Stated with charging, the theorem is proved, and charging is necessary: the theorem is an equivalence (§XIV.7).

§14.6. The step from compatible classes to agreeing representatives is where the text is shortest. The equivalence of structured multisections compares Λ, the index sets and the correspondences, not the sections, so the text's identification $s^x_{F,i} = s^x_{F',i}$ is a choice of representatives, which Theorem 14.6.3 takes as its input (§XIV.28, gap G.173). Everything else in §14.6 is local: faces are closed and saturated, every boundary point lies on finitely many, near a point every face through a nearby point contains it, and a local face of a tame chart lies in one face (§XIV.27). These four facts, with the gluing criterion for sc$^+$ on faces, are the whole proof of the gluing.

How the chapter is used later. Theorem 14.1.9 is the tool by which the transversality results of Chapter 15 and the cobordism results of Chapter 16 control a multisection near the boundary. Theorem 15.3.9 (Part XV) uses it in its charged form, with the same two readings, tame strong bundle charts at every object and charging; the cut-off step of its proof uses the extension of face-wise sc$^+$ sections of Proposition 14.1.4 (§XIV.3) and Definition 14.1.3 (1) read through the charts (§XIV.2). Theorem 16.5.7 (Part XVI) uses it in one representative of a strong polyfold bundle, and the transport between representatives is Proposition 14.1.8 over ∂X (§XIV.6). In both places the remark of §XIV.7 has a counterpart: a Lean statement that takes the uncharged form of Theorem 14.1.9 as a hypothesis, or asks its conclusion for every structurable Λ, holds only without boundary, and the charged form replaces it. What these later chapters need from Chapter 14 is therefore exactly what is proved here: the charged theorem, its necessity, the transport over ∂X, and the half-space witness with boundary.

A note on how the proof is organized. The text proves Theorem 14.1.9 in one pass, introducing the objects of each section from those of the previous one. The formalization splits each step into an abstract statement over a structure that names its inputs, and an instance built from the objects of the construction (§§XIV.13, XIV.25). The split made three things visible. First, which properties of the previous objects each step actually uses: Theorem 14.5.5 uses neither properness nor closures, Lemma 14.5.1 not tameness, Proposition 14.4.14 not Definition 14.4.11 (2). Second, where a step uses a property its statement does not list: Proposition 14.5.4 and the support of the cut-offs. Third, where each standing hypothesis enters: paracompactness of $|X|$ through the good systems of Theorem 14.1.6 and Part XIII and through the size control; tameness through Proposition 14.1.1 and the faces; the sc-smooth partitions of unity and the

tame strong bundle charts through the local extensions of Propositions 14.1.4 and 14.4.14, the charts also through Definition 14.1.3 (1) and its transport (§XIV.6). Each of these is named in the subsection where it is used.

Part XV. Transversality and invariants (HWZ Chapter 15, §§15.1–15.4)

Chapter 15 (Springer 2021, pp. 683–703; the 2017 numbers in parentheses) is the perturbation theory of an sc-Fredholm section functor f of a strong bundle $(P : W \to X, \mu)$ over an ep-groupoid by sc$^+$-multisections Λ, and the invariants obtained from the perturbed solution sets $\Lambda \circ f$. §15.1 defines the linearization $T(f, \Lambda)$ of $\Lambda \circ f$, a section functor with values in the formal sums GrF of sc-Fredholm operators, and proves that it is well defined through a separation argument for finitely many sections (Theorem 15.1.1, Remark 15.1.2, Proposition 15.1.3, Lemmas 15.1.4, 15.1.5, Remark 15.1.6, Definition 15.1.7 (2017: Theorem 15.1, Remark 15.1, Proposition 15.1, Lemmas 15.1, 15.2, Definition 15.1; Remark 15.1.6 is new in 2021)). §15.2 defines transversality and good position and describes the local solution sets, which make $\Lambda \circ f$ a branched ep$^+$-subgroupoid (Definitions 15.2.1, 15.2.4, Theorems 15.2.2, 15.2.5, Remarks 15.2.3, 15.2.6). §15.3 controls compactness by an auxiliary norm, defines admissible perturbations and general position, and constructs perturbations: Theorem 15.3.7 (general position), Theorem 15.3.9 (transversal extension of boundary data) and Corollary 15.3.10 (regular perturbations exist, and any two are joined over the cylinder $[0, 1] \times X$). §15.4 orients $\Lambda \circ f$ by an orientation of f (Theorem 15.4.1, Definition 15.4.2) and integrates sc-differential forms over it: Stokes' theorem (Theorem 15.4.3) and the invariant on de Rham cohomology (Corollary 15.4.4). This Part retells the formal proofs in the book's order: §15.1 in §§XV.1–XV.11, §15.2 in §§XV.12–XV.16, §15.3 in §§XV.17–XV.33 (the definitions in §§XV.17–XV.20, Theorem 15.3.7 in §§XV.21–XV.26, Theorem 15.3.9 in §§XV.27–XV.29, Corollary 15.3.10 in §§XV.30–XV.33), §15.4 in §§XV.34–XV.37; then what is not formalized (§XV.38) and what the formalization taught us (§XV.39).

What is proved, and what is not. *§15.1. Theorem 15.1.1* (narrower) is proved in its substance in a stronger form: the formal sum $\sum_{f(x)=s_i(x)} \sigma_i \cdot (f - s_i)'(x)$ does not depend on the local sc$^+$-section structure or on the chart, at every level-1 point, for any sc-smooth f, with no use of positivity of the weights or of the functoriality of Λ (§§XV.2, XV.7); the value $T(f, \Lambda)(x)$ is Definition 15.1.7 (§XV.8); the functor property $T(f, \Lambda)(t(\varphi)) = \varphi_* T(f, \Lambda)(s(\varphi))$ holds at all level-1 points, with no added hypothesis (§XV.9, gap G.144 closed). The row is narrower for one reason: the summands are proved sc-Fredholm in the chart reading and for f with Part I's tame germ data (§XV.11, gap G.145 closed). *Remark 15.1.2* and *Definition 15.1.7* are restated (§§XV.2, XV.8). *Lemmas 15.1.4 and 15.1.5* are proved in a stronger, purely topological form (§§XV.4, XV.5), *Remark 15.1.6* with "slightly" made explicit (§XV.6). *Proposition 15.1.3* is proved with the added hypothesis that the base point is not isolated; at an isolated point, for instance for the one-point local model of a zero-dimensional X, it does not hold as we read it, since no sequence $x_k \neq x_0$ converges to x_0. The case is degenerate and does not reach Theorem 15.1.1, whose formal proof does not use the proposition (§§XV.3, XV.7). The proof of Theorem 15.1.1 is read in two places: the separation and the limit run in the level-1 topology, the "weak topology" being pointwise convergence of operators; and

the final sum is presumably over the i with $f(0) = s_i(0)$ (§XV.7).

§15.2. Definitions 15.2.1 and 15.2.4 are restated, the first with "nonzero" and "sc-Fredholm" automatic (§§XV.12, XV.15). Theorems 15.2.2, 15.2.5 and Remark 15.2.3 (narrower) are proved with Part I's tame germ data for f, inherited from Part I's Theorem 3.6.8, on which they rest; this is the only hypothesis they add. Their "tame" submanifolds and tame branched ep$^+$-subgroupoids (Definition 9.3.6) are proved (§§XV.14, XV.16, gap G.150 closed). "The ep-groupoid $U(x)$" of Remark 15.2.3 is read as the translation groupoid $G_x \ltimes U(x)$; on it the statements hold as printed, the paracompactness of the support included (§XV.14, gap G.152 closed). Their global forms on X take a paracompact orbit space of the support, Definition 9.1.2 (1), which is new in 2021 and which the remarks do not address. The closing sentence of Theorem 15.2.5, under general position, is proved for tame X (§XV.16, gap G.151 closed). Remark 15.2.6 is prose.

§15.3. The paragraph before Definition 15.3.1, Definition 15.3.3 with its example, and the first sentence of Remark 15.3.6 are proved as stated; Definitions 15.3.1 and 15.3.5 are restated (§§XV.17, XV.18, XV.20). The rest of Remark 15.3.6 is proved at every point of the support, not only on ∂X, with the inherited tame germ data and, for the branched ep$^+$-subgroupoid, a paracompact support (§XV.20, gap G.161 closed). The products remark after Definition 15.3.3: product ep-groupoids, product strong bundles, products of sections and section functors and the auxiliary norm $\max(N, N')$ are formalized; $f \times f'$ sc-Fredholm and $\Lambda \times \Lambda'$ (Remark 15.3.4) are not (§XV.19, gap G.160, in part). *Theorem 15.3.7* (explicit) is proved with the text's hypotheses, the inherited tame germ data being the only one not printed, with no good system and no paracompactness of $|X|$, as Remark 15.3.8 says; the addendum "structurable" needs a good system, which is necessary for it and which exists for paracompact $|X|$; its "in particular" holds with "tame" (§§XV.21–XV.26; gap G.162 closed for Theorem 15.3.7). *Theorem 15.3.9* (narrower) is proved in the charged form, the boundary multisection having non-empty index sets, which the conclusion forces, from tame strong bundle charts and one open proposition, the relative local families of steps (c)–(d) (gap G.178); its face condition is asked for every sc$^+$ extension (gap G.179); step (a) is proved (gap G.177 closed), step (b) is Theorem 14.1.9 in its charged form (Part XIV), and the Sard and compactness parts of steps (c)–(d) are proved (§§XV.27–XV.29). Its witnesses have no boundary and zero fibres. *Corollary 15.3.10* (1) follows from Theorem 15.3.7 for paracompact $|X|$, with bump functions and the tame germ data, the tameness of X derived from $d_X \equiv 0$ (§§XV.30, XV.31, gap G.183 closed); (2) is proved with an explicit interpolated auxiliary norm (§XV.31); (3) is reduced to the charged Theorem 15.3.9 on $[0, 1] \times X$, with the partitions of unity of the cylinder proved from those of X (gap G.181 closed), the structurability of the glued boundary data proved given that lifted sc$^+$-sections are sc$^+$ on the faces (gap G.193), and the face condition of the glued data and tame strong bundle charts on the cylinder as hypotheses (gaps G.180, G.189) (§§XV.32, XV.33). The last paragraph of the proof of the corollary is proved as printed (§XV.33). Remarks 15.3.2 and 15.3.11 are prose.

§15.4. Theorem 15.4.1 and Definition 15.4.2 (narrower) are proved at a single point, in Part I's chart reading: the operators $(f - s_i)'(y)$ lie in Part I's $\mathrm{Lin}(f, y)$, the canonical lift exists, has the text's formula, is unique and does not depend on the local structure, and the kernel orientations are defined; their assembly into an orientation of $\Lambda \circ f$ is open (§XV.34, gap G.159, in part). Theorem 15.4.3 (narrower) is proved with the orientation as data, by Part IX's Stokes theorem (§XV.35). Corollary 15.4.4 (narrower) is proved by the text's cobordism argument from oriented cobordisms between regular perturbations; on the cylinder the ends and the splitting of the boundary measure are proved, and the oriented end identities are a hypothesis (gaps G.182, G.190); the effective version adds the local unique continuation property on the cylinder (gap G.191) (§§XV.36, XV.37). Remark 15.4.5 is prose.

Open: G.159 and G.160 in part; G.162 for Theorem 15.3.9 and Corollary 15.3.10 (3); G.178–G.180, G.182, G.189–G.191, G.193 (§XV.38). *Closed:* G.144, G.145, G.150–G.152, G.161, G.177, G.181, G.183. Proposition 15.1.3 at an isolated point is the one statement of the chapter that does not hold as we read it, a degenerate case; no statement of §§15.2–15.4 was found not to hold as we read it.

The decisions that shape the chapter. (1) *Formal sums are finitely supported functions.* $\mathrm{GrF}(x)$ is the type of finitely supported functions from the linear maps $T_xX \to W_x$ to $\mathbb{Q}^{\geq 0}$, defined at every level-1 point `Chapter15/LinearizationIntrinsic · SBLocalization.GrF`; that the operators are sc-Fredholm is proved for the operators that occur, not built into the type. On a strong bundle model the operators are $T_zO \to F_0$ `Chapter15/LinearizationModel · Linearization15.GrFModel`. (2) *The separation argument is pure topology.* Proposition 15.1.3, Lemmas 15.1.4, 15.1.5 and Remark 15.1.6 are proved for finitely many continuous maps into a Hausdorff space and applied on the level-1 subspace of the model, where the sections and their derivatives are continuous. (3) *Pairs, not operators.* The proof of Theorem 15.1.1 compares finite formal sums of pairs (value, derivative) over all branches, $\mathrm{wsum}(a,\sigma)(q) = \sum_{i:a_i=q}\sigma_i$ `Chapter15/SeparationLemmas · Linearization15.wsum` with masses of sets `Chapter15/SeparationLemmas · Linearization15.mass` `Chapter15/SeparationLemmas · Linearization15.mass_eq_of_wsum_eq`; the sum of the theorem is the part with first entry $f(y)$. (4) *A branch is a section problem of Part I.* A local sc$^+$-section s_i on an open O is a global sc$^+$-section of the restricted bundle $W|_O$, and $(f-s_i)|_O$ is an sc-Fredholm section there (§XV.10); every analytic statement of §§15.2–15.4 is Part I's theorem applied branch by branch. The price is Part I's hypothesis: *tame germ data* for f, inherited from Part I's Theorems 3.1.18 and 3.6.8, which are proved for it; with the untamed notion of 2021 Theorem 3.6.8 does not hold as we read it (Part III). (5) *Operators are read in charts.* T_xX and W_x carry no sc-structure in the project; "sc-Fredholm", "onto on T^R_xX" and "$\in \mathrm{Lin}(f,y)$" are read in a strong bundle chart, through the identifications that define the intrinsic operators, and shown independent of the chart where it matters. (6) *The cylinder is a product with Part I's cube.* $[0,1]\times X$ is built as $[0,1]^n \times X$ with $n=1$, so that Part I's parametrized Fredholm theory applies to $\tilde{f}$ (§XV.30). (7) *Boundary data are charged.* A multisection over ∂X is taken with non-empty index sets, as the text's "sc$^+$-multisection over ∂X" has them; Theorem 15.3.9 needs it, and the uncharged Lean statement does not hold when $\partial X \neq \emptyset$ (§XV.27). (8) *Open steps are named propositions.* Where a theorem rests on a step that is not proved, the step is a named statement (for instance the relative local families of Theorem 15.3.9, the oriented end identities of Corollary 15.4.4), taken as a hypothesis with a witness, and the theorem is proved from it.

Map.

- *The linearization (§15.1).* `Chapter15/SeparationLemmas`: formal sums of points, Proposition 15.1.3 with its witness and the isolated point, Lemmas 15.1.4, 15.1.5, Remark 15.1.6, the limit step and the core lemma (§§XV.1, XV.3–XV.7). `LinearizationModel`: GrF on a strong bundle model, level-1 continuity and locality of derivatives, Theorem 15.1.1 and Remark 15.1.2 on the model (§§XV.2, XV.7). `Linearization`: principal parts and counts in a strong bundle chart, Theorem 15.1.1 in a chart, the chart form of Definition 15.1.7 (§§XV.7, XV.8). `LinearizationIntrinsic`: intrinsic operators, the change of chart, Theorem 15.1.1 with intrinsic operators, Definition 15.1.7 (§§XV.1, XV.7, XV.8). `LinearizationFunctor`: the action of morphisms on GrF and the functor property (§XV.9).
- *Branches as section problems, and §15.2.* `LocalScPlus`, `LocalIFT`: local sc$^+$-sections on $W|_O$, the sections $f-s_i$, the chart linearization, local solution sets (§XV.10). `FredholmSummands`: the sc-Fredholm summands (§XV.11). `Transversality`: Definition 15.2.1, Theorem 15.2.2, Remark 15.2.3 (§§XV.12–XV.14). `BoundaryPerturbation`: Definition 15.2.4, Theorem 15.2.5 (§§XV.15, XV.16). `InteriorPerturbationWitness`, `GoodPositionWitness`, `TameWitness`: witnesses for §15.2. `Tame–`

`Branched`: tame local solution sets and the tame forms of Remarks 15.2.3, 15.3.6, Theorems 15.2.5, 15.3.7 (§§XV.14, XV.16, XV.20, XV.21). `RestrictedEp`: the translation groupoid $G_x \ltimes U(x)$ and the statements on it (§§XV.14, XV.16). `GeneralPositionLocal`: general position at a point, its relation to good position and to Part I, Theorem 15.2.5 under general position (§XV.16).

- *Definitions of §15.3 and products.* `ControllingPairs`: Definitions 15.3.1, 15.3.3, 15.3.5, the paragraph before Definition 15.3.1, the example after Definition 15.3.3, the first sentence of Remark 15.3.6 (§§XV.17, XV.18, XV.20). `ProductEp`: product ep-groupoids (§XV.19). `ProductStrongBundle`, `ProductBundle`, `ProductBundleLevels`, `ProductBundleMap`, `ProductEpBundle`, `ProductAuxNorm`: product strong bundles, their levels and sections, the product over $X \times X'$, $\max(N, N')$ (§XV.19). `GoodPositionBranches`, `GeneralPositionBranched`: the rest of Remark 15.3.6, the statement of Theorem 15.3.7 and its "in particular" (§§XV.20, XV.21).
- *Theorem 15.3.7.* `ParamFamily`: linear families, (15.1), sums of families, norm and support bounds (§XV.22). `GeneralPositionAssembly`: the assembly from the local families and the parametric step (§XV.22). `ParamOntoTransport`, `LocalFamilies`, `LocalSeeds`: (15.1) with vectors and along morphisms, seeds, the local families (§XV.23). `ParamOntoBridge`: (15.1) and Part I's conditions (i)–(ii) (§XV.24). `LocalSlice`, `BranchChart`, `ParametricGeneralPosition`: the local Sard step, a branch as a Part I parametrized section, achieving global transversality (§XV.25). `GeneralPositionPointwise`, `GeneralPositionGoodSystem`, `GeneralPositionExistence`: the theorem with the text's hypotheses, the structurable form, Remark 15.3.8 (§XV.26).
- *Theorem 15.3.9.* `TransversalExtension`: the face condition and the reduction to the steps of the proof (§§XV.27, XV.29). `CutoffFunctor`: step (a) (§XV.28). `RelativeFamilies`, `RelativeBranch`, `RelativeParametric`, `RelativeReduction`: relative (15.1), relative families, the relative parametric step (§XV.29). `ChargedExtensionFibres`: the charged statement and the theorem (§§XV.27, XV.29). `ChargedExtensionCylinder`: the uncharged Lean statement with boundary (§XV.27) and Corollary 15.3.10 (3) with the charged theorem (§XV.33).
- *The cylinder and Corollary 15.3.10.* `CubeEp`: $[0,1]^n \times X$, $\widetilde{W}$, $\tilde{f}$ (§XV.30). `Chapter5/DegeneracyZeroTame`: $d_X \equiv 0$ implies tame (§XV.30). `CubeAuxNorm`: Corollary 15.3.10 (2) (§XV.31). `RegularPerturbations`, `Cylinder`: regular perturbations, Corollary 15.3.10 (1), the orbit space of the cylinder (§§XV.30, XV.31, XV.33). `CylinderGlue`: the glued boundary data, the last paragraph of the proof (§§XV.32, XV.33). `Chapter5/CubePartitions`, `CylinderPartitions`: partitions of unity of the cylinder (§XV.32). `CubeLift`, `GlueStructurable`: lifted structures and the structurability of the glued data (§XV.32).
- *§15.4.* `OrientedLinearizations`, `CanonicalLift`: oriented formal sums, the canonical lift, Theorem 15.4.1 and Definition 15.4.2 at a chart point (§XV.34). `PerturbedStokesInvariants`: Theorem 15.4.3, the cobordism argument, Corollary 15.4.4 (§§XV.35, XV.36). `CylinderEnds`, `CylinderCobordism`: the ends of the cylinder, the boundary measure, Corollary 15.4.4 on the cylinder and its effective version (§XV.37).

Throughout, $(P : W \to X, \mu)$ is a strong bundle over an ep-groupoid, f an sc-Fredholm section functor, and Λ an sc$^+$-multisection with local sc$^+$-section structures (s_i, σ_i), the local representations of Definition 13.2.1 on open sets `Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsLocalRepOn` (Part XIII). "Part I's" refers to Part I of the book (Chapters 1–6, M-polyfolds), whose statements Parts I–VI of this book retell.

XV.1 The preamble of §15.1: $\mathrm{GrF}(x)$ and finite formal sums

The text (p. 683) fixes, at a smooth point x, the set of sc-Fredholm operators $L : T_xX \to W_x$, and lets $\mathrm{GrF}(x)$ consist of the finite formal sums $\sum \sigma_L \cdot L$ with non-negative rational coefficients; a morphism $\varphi : x \to y$ acts by $\varphi_* L \circ T\varphi = \mu(\varphi, L(\cdot))$, and $\mathrm{GrF}(X) \to X_\infty$ becomes a category over X. Three objects of the formalization stand for this preamble.

$\mathrm{GrF}(x)$ (restated) `Chapter15/LinearizationIntrinsic · SBLocalization.GrF`. For a level-1 point x, $\mathrm{GrF}(x)$ is the type of finitely supported functions from the linear maps $T_xX \to W_x$ to $\mathbb{Q}^{\geq 0}$, where T_xX is the project's tangent fibre of the object M-polyfold (Part II of the book, with the linear structure of Chapter 2) and $W_x = P^{-1}(x)$ is the fibre with its vector space structure. Two departures from the text are deliberate. First, the point ranges over X_1, not only over X_∞: the linearization of a section at a zero is defined at level-1 points already, and everything proved below holds there. Second, the operators are all linear maps, not only the sc-Fredholm ones. The sc-Fredholm property is a property of the operators that actually occur, proved for them in §XV.11; it is not built into the type, so that $\mathrm{GrF}(x)$ is a plain free commutative monoid on which sums, push-forwards and supports behave without side conditions. The text's $\mathrm{GrF}(X)$ and the category structure are not built as such; the action of morphisms is defined in §XV.9, where it is needed.

On a strong bundle model `Chapter15/LinearizationModel · Linearization15.GrFModel`. On a strong bundle model $U \lhd F$ with retraction R and base retraction r, $O = r(U)$, the same object at a level-1 point z is the type of finitely supported functions on the bounded operators $T_zO \to F_0$, where $T_zO = \operatorname{range} Dr(z)$ is the tangent space of the retract, as in Part I's linearization in a chart `Chapter3/LinearizationCharts · linAt`. This is the form in which the analysis is done.

Intrinsic operators from chart operators. An operator of a strong bundle chart $c = (\varphi, \Phi)$ around x becomes an element of $\mathrm{GrF}(x)$ in two steps. First $L : E_0 \to F_0$ is read along T_xX `Chapter15/LinearizationIntrinsic · SBLocalization.chartOp`: $\alpha \mapsto L(T\varphi\,\alpha)$, where $T\varphi$ identifies T_xX with the tangent space $T_{\varphi(x)}O$ of the model `Chapter15/LinearizationIntrinsic · SBLocalization.chartOp_apply`. Then the values are pulled back to W_x through the fibre part $\Phi_x : W_x \to F_0$ of the chart, which is linear and injective `Chapter15/LinearizationIntrinsic · SBLocalization.toIntr`: if every value $L(T\varphi\,\alpha)$ lies in the range of Φ_x, the operator is $\Phi_x^{-1} \circ L \circ T\varphi : T_xX \to W_x$, and otherwise it is 0. The default value is never used: at a zero of a section that is sc-smooth in the chart, the chart derivative takes values in $\Phi_x(W_x)$ (§XV.7, step (f)), and then $\Phi_x \circ (\text{intrinsic operator}) = L \circ T\varphi$ `Chapter15/LinearizationIntrinsic · SBLocalization.fiberLin_toIntr`.

Finite formal sums of points. The proof of Theorem 15.1.1 compares formal sums of *points*, not of operators, and the formalization makes these first-class. For finitely many points a_i of a set Q with weights σ_i in a commutative monoid, the coefficient of q in $\sum \sigma_i \cdot a_i$ is

$$\mathrm{wsum}(a, \sigma)(q) = \sum_{i : a_i = q} \sigma_i$$

`Chapter15/SeparationLemmas · Linearization15.wsum`, and the mass of a set $N \subseteq Q$ is $\mathrm{mass}(a, \sigma)(N) = \sum_{i : a_i \in N} \sigma_i$ `Chapter15/SeparationLemmas · Linearization15.mass`. The mass is the sum of the coefficients over any finite set S containing all a_i, restricted to N `Chapter15/SeparationLemmas · Linearization15.mass_eq_sum_wsum` (exchange the two finite sums), so two families with the same coefficients have the same mass on every set: take S the union of the two finite images `Chapter15/SeparationLemmas · Linearization15.mass_eq_of_wsum_eq`. The coefficient of q' in the image $\sum \sigma_i \cdot \psi(a_i)$ is the mass of $\psi^{-1}(q')$ `Chapter15/SeparationLemmas · Linearization15.wsum_map`, so equal formal sums have equal images under every map `Chapter15/SeparationLemmas · Linearization15.wsum_map_eq_of_wsum_eq`. This last remark is the formal content of "se-

lect the terms with $s_i(y) = f(y)$, then forget the value": both are images, and images respect equality.

XV.2 Theorem 15.1.1 (2017: 15.1) and Remark 15.1.2 (2017: 15.1): the statements as formalized

The text. For a strong bundle $(P : W \to X, \mu)$ over an ep-groupoid, an sc-Fredholm section f and an sc$^+$-multisection Λ, there is a section functor $T(f,\Lambda)$ of $\mathrm{GrF}(X) \to X_\infty$, uniquely characterized by (1) $T(f,\Lambda)(x) = 0$ off $\mathrm{supp}(\Lambda \circ f)$, and (2) for x in the support and any local sc$^+$-section structure $(s_i,\sigma_i)_{i\in I}$ describing Λ around x, $T(f,\Lambda)(y) = \sum_{\{i: f(y)=s_i(y)\}} \sigma_i \cdot (f - s_i)'(y)$ at smooth y near x (p. 684). The substance is that the right side of (2) does not depend on the structure; existence and uniqueness then follow from the covering of X by structures. A local sc$^+$-section structure is the local representation of Definition 13.2.1 (Part XIII) on an open set: sc$^+$-sections $s_1,\dots,s_k$ on O with positive rational weights summing to 1 such that $\Lambda(w) = \sum_{i: w = s_i(P(w))} \sigma_i$ for w over O `Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsLocalRepOn`, with s_i an sc$^+$-section on O `Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsScPlusSectionOn`, and an sc$^+$-multisection is a functor $W \to \mathbb{Q}^{\geq 0}$ with such a structure on the domain of a natural representation around every object `Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsScPlusMultisection`.

The formalization states the theorem three times, on three levels of the reduction "without loss of generality $X = O$", and then once more for the value of Definition 15.1.7 (§XV.8) and for the functor property (§XV.9).

On a strong bundle model (stronger than the text's local statement) `Chapter15/LinearizationModel · Linearization15.theorem_15_1_1_model`. Let $U \lhd F$ be a strong bundle model (U relatively open in a partial quadrant, R a strong bundle retraction, $O = r(U)$), and let $\hat f$, $\hat s_1,\dots,\hat s_k$, $\hat t_1,\dots,\hat t_l$ be principal parts $E_0 \to F_0$ with $\hat f \circ r$, $\hat s_i \circ r$, $\hat t_j \circ r$ sc-smooth on U. The formal sum at a level-1 point z is

$$\sum_{i:\hat s_i(z)=\hat f(z)} \sigma_i \cdot (\hat f - \hat s_i)'(z) \in \mathrm{GrF}_{\mathrm{model}}(z), \qquad (\hat f - \hat s_i)'(z) = D((\hat f - \hat s_i)\circ r)(z)|_{T_zO}$$

`Chapter15/LinearizationModel · Linearization15.linSumModel`, with its coefficient of an operator ℓ the sum of the σ_i with $\hat s_i(z) = \hat f(z)$ and $(\hat f - \hat s_i)'(z) = \ell$ `Chapter15/LinearizationModel · Linearization15.linSumModel_apply`. If the two structures give the same weighted count $\sum_{i:\hat s_i(y)=v} \sigma_i = \sum_{j:\hat t_j(y)=v} \tau_j$ of every value v at every $y \in O \cap N$, N open, then the two formal sums agree at every level-1 point of $O \cap N$. The same holds after replacing each operator $D((\hat f - \hat s_i)\circ r)(z)$ by its image under any map ψ of operators `Chapter15/LinearizationModel · Linearization15.linSumModelMap` `Chapter15/LinearizationModel · Linearization15.linSumModelMap_apply` `Chapter15/LinearizationModel · Linearization15.theorem_15_1_1_model_map`; the map that matters is the passage to intrinsic operators. The statement is stronger than what the proof of the text needs in two ways: all level-1 points instead of the smooth ones, and no condition on Λ at all, only that the two structures have the same counts. Neither positivity of the weights nor functoriality is used.

In a strong bundle chart (stronger) `Chapter15/Linearization · SBLocalization.theorem_15_1_1`. For an sc-Fredholm section functor f and two local sc$^+$-section structures (s_i,σ_i) on O and (t_j,τ_j) on O' of the same Λ, the formal sums $\sum_{i:f(y)=s_i(y)} \sigma_i \cdot (f - s_i)'(y)$, read in a strong bundle chart c with domain in $O \cap O'$ `Chapter15/Linearization · SBLocalization.linSumChart`, agree at every level-1 point of the chart. The

same holds for any sc-smooth section f `Chapter15/Linearization · SBLocalization.linSumChart_eq`; this is what the proof uses.

With intrinsic operators (narrower, as the row of the theorem; stronger in its substance) `Chapter15/LinearizationIntrinsic · SBLocalization.theorem_15_1_1_intrinsic`. The formal sum in $\mathrm{GrF}(x)$ through a chart c,

$$\sum_{i:f(x)=s_i(x)} \sigma_i \cdot (f-s_i)'(x), \qquad (f-s_i)'(x) = \Phi_x^{-1} \circ D((\hat{f}-\hat{s}_i)\circ r)(\varphi(x)) \circ T\varphi$$

`Chapter15/LinearizationIntrinsic · SBLocalization.linSumIntr`, is the same for two structures of Λ on open O, O', computed through any chart c with domain in O and any chart c' with domain in O', at every $x \in X_1$ in both domains. This is the text's (2) with the operators in their intrinsic form, and the formulation in which Definition 15.1.7 is made.

Why the row is narrower. What Theorem 15.1.1 claims beyond the independence is (a) that $T(f,\Lambda)$ is a *section functor*, which is proved at all level-1 points in §XV.9, and (b) that its values lie in GrF, i.e. that the summands are sc-Fredholm. (b) is proved in §XV.11 only in a chart reading, since T_xX and W_x carry no sc-structure of their own in the project, and only for f with Part I's tame germ data, the hypothesis of Part I's implicit function theorem on which the proof rests. That inherited hypothesis is the only reason the row is narrower; the independence itself is proved in a stronger form. The text's "uniquely characterized" is the remark that (1) and (2) determine the value at every point, which in the formalization is Definition 15.1.7 with $T(f,\Lambda)(x)$ equal to the sum of *any* local data (§XV.8).

Remark 15.1.2 (restated). The text observes that $(f-s_i)'(y)$ is undefined where $f(y) \neq s_i(y)$ but is not counted, and that with the empty sum equal to 0, (1) follows from (2). In the formalization the operator $(\hat{f}-\hat{s}_i)'(z)$ is defined for every i, and the sum is filtered by $\hat{s}_i(z) = \hat{f}(z)$; so the first half of the remark is the definition of the formal sum. The second half is proved on each level. *On the model* `Chapter15/LinearizationModel · Linearization15.remark_15_1_2_model`: if the weights are positive and the weighted count of $\hat{f}(z)$ is 0, then each term of that count is 0, so no i has $\hat{s}_i(z) = \hat{f}(z)$ (a term with $\hat{s}_i(z) = \hat{f}(z)$ would contribute $\sigma_i > 0$), every summand of the formal sum is the empty case, and the formal sum is 0. The same counting gives the description of the support used by Definition 15.2.1: with positive weights an operator ℓ has a nonzero coefficient iff $\ell = (\hat{f}-\hat{s}_i)'(z)$ for some i with $\hat{s}_i(z) = \hat{f}(z)$ `Chapter15/LinearizationModel · Linearization15.mem_support_linSumModel_iff`. *In a chart* `Chapter15/Linearization · SBLocalization.remark_15_1_2`: where $\Lambda(f(y)) = 0$, the weighted count of $\hat{f}(\varphi(y))$ in the chart is $\Lambda(\Phi^{-1}(\varphi(y), \hat{f}(\varphi(y)))) = \Lambda(f(y)) = 0$ (the count formula of §XV.7, step (e)), so the model remark applies. *Intrinsically*, Theorem 15.1.1 (1) `Chapter15/LinearizationIntrinsic · SBLocalization.linearization_eq_zero`: $T(f,\Lambda)(x) = 0$ where $\Lambda(f(x)) = 0$, by the same count read through the data that define $T(f,\Lambda)(x)$ (§XV.8).

XV.3 Proposition 15.1.3 (2017: 15.1): separating sequences

The separation property at a point z for a partition $e : I \to \{1,\dots,p\}$ of the index set `Chapter15/SeparationLemmas · Linearization15.IsSeparatedAt`: (1) $s_i(z) = s_{i'}(z)$ iff $e(i) = e(i')$, and (2) if $e(i) = e(i')$ then $s_i = s_{i'}$ on a neighbourhood of z. This is the conclusion of the proposition at one point x_k.

Statement (narrower) `Chapter15/SeparationLemmas · Linearization15.proposition_15_1_3_hyp`. Let Z be a first countable T_1 space, s_i, $i \in I$ finite, maps continuous on an open $V \ni x_0$ with values in a Hausdorff space, and suppose that x_0 is not isolated. Then there are $x_k \in V$ with $x_k \neq x_0$ and $x_k \to x_0$, and

one surjective partition $e : I \to \{1, \dots, p\}$, such that the separation property holds at every x_k. The text states it on the local model O, with the metric of E_0, $x_0 = 0$ and the sections of a local sc$^+$-section structure. The formal statement is more general in its setting (topological, no sc-structure, the maps only continuous) and narrower by one hypothesis.

Proof. *Step 1, points near x_0 where the maps are dichotomous.* Call z *locally dichotomous* for the family if every pair of the maps either coincides on a neighbourhood of z or differs at z `Chapter15/SeparationLemmas · Linearization15.IsLocDich`. Every nonempty open set on which the maps are continuous contains such a point `Chapter15/SeparationLemmas · Linearization15.exists_isLocDich_mem`: Lemma 15.1.5 in its topological form (§XV.5) gives a nonempty open W inside it on which each pair either coincides or differs everywhere, and any point of W will do (coincidence on W is coincidence near the point, since W is open). Now take a decreasing countable basis (u_k) of neighbourhoods of x_0, which exists by first countability. For each k the set $\mathrm{int}(u_k) \cap V \setminus \{x_0\}$ is open, because Z is T_1 so that $\{x_0\}$ is closed; and it is nonempty, because it belongs to the punctured neighbourhood filter of x_0, which is not trivial since x_0 is not isolated. So it contains a locally dichotomous point z_k; $z_k \neq x_0$, $z_k \in V$, and $z_k \to x_0$ since $z_k \in u_k$ and the u_k form a decreasing basis.

Step 2, the subsequence `Chapter15/SeparationLemmas · Linearization15.exists_isSeparatedAt_subseq`. At each z_k the *pattern* of coincidences is the relation $\{(i,j) : s_i(z_k) = s_j(z_k)\}$ on $I \times I$. There are finitely many such relations, so one of them, P, occurs for infinitely many k (a map from $\mathbb{N}$ to a finite set has an infinite fibre), and an extraction $k \mapsto \phi(k)$, strictly increasing, picks those k. The partition e is taken from the values at $z_{\phi(0)}$: $e(i) = e(j)$ iff $s_i(z_{\phi(0)}) = s_j(z_{\phi(0)})$ `Chapter15/SeparationLemmas · Linearization15.exists_fin_partition`, the classes of equal values numbered by a finite set. Since the pattern is P at every $z_{\phi(k)}$, (1) holds at every point of the subsequence. For (2): if $e(i) = e(j)$ then $s_i(z_{\phi(k)}) = s_j(z_{\phi(k)})$, and since $z_{\phi(k)}$ is locally dichotomous, the pair cannot differ there, so it coincides near $z_{\phi(k)}$. The sequence of the proposition is $x_k = z_{\phi(k)}$.

How this departs from the text's proof. The text picks $y_k \to 0$, $y_k \neq 0$, applies Lemma 15.1.5 on small balls around y_k to get z_k with partitions $I = I_1^k \sqcup \cdots \sqcup I_{p_k}^k$, and then takes successive subsequences making I_1^k, I_2^k, … constant. The formal proof takes a single subsequence on which the whole pattern is constant, by the pigeonhole principle on the finite set of relations on I; the result is the same. The points come from a neighbourhood basis rather than from a sequence chosen in advance, so no metric is needed.

The added hypothesis, and the isolated point. That x_0 is not isolated is not derived from the text; it is what makes the punctured neighbourhoods nonempty in Step 1. Its witness is two maps $z \mapsto 0$ and $z \mapsto z$ on $\mathbb{R}$ at 0 `Chapter15/SeparationLemmas · Linearization15.proposition_15_1_3_hyp_witness`, where all hypotheses hold and the proposition applies. **At an isolated point, Proposition 15.1.3 does not hold as we read it.** If $\{x_0\}$ is open, no sequence $x_k \neq x_0$ converges to x_0: convergence would put some x_k in the open set $\{x_0\}$ `Chapter15/SeparationLemmas · Linearization15.not_proposition_15_1_3_of_isolated`. This happens for the one-point local model $O = \{0\}$ of a zero-dimensional X `Chapter15/SeparationLemmas · Linearization15.not_proposition_15_1_3_point`. The case is degenerate, and nothing depends on it: the formal proof of Theorem 15.1.1 does not use the proposition, because its core lemma needs separated points in every neighbourhood of x_0, and x_0 itself may be one of them (§XV.7). At an isolated point the theorem therefore holds without change.

XV.4 Lemma 15.1.4 (2017: 15.1): finite closed covers of a ball

Statement (stronger) `Chapter15/SeparationLemmas · Linearization15.lemma_15_1_4`. In any pseudo-metric space, if a ball $B_\varepsilon(y)$, $\varepsilon > 0$, is the union of finitely many sets A_i that are closed in $B_\varepsilon(y)$, then one of the A_i has nonempty interior. The text states it for O with the metric of E_0 (p. 685); the formal statement holds in every pseudo-metric space.

Proof. *The topological core* `Chapter15/SeparationLemmas · Linearization15.interior_biUnion_eq_empty`: in any topological space, a finite union of closed sets with empty interiors has empty interior. By induction over the finite index set: the empty union is empty; and if A is closed with empty interior and B (the union so far) has empty interior, then $A \cup B$ has empty interior, Mathlib's fact for the union of a closed set and a set with empty interior. *The cover form* `Chapter15/SeparationLemmas · Linearization15.exists_nonempty_interior_of_finite_closed_cover`: a nonempty open set V covered by finitely many closed sets meets the interior of one of them. Otherwise all interiors are empty, so the union has empty interior by the core; but V is open and contained in the union, so every point of V lies in the interior of the union. *The lemma* is the cover form in the subspace $B_\varepsilon(y)$, which is nonempty (it contains y) and open in itself: the preimages of the A_i in the subspace are closed by hypothesis and cover it, so one of them has a point x in its interior in the subspace. The image of that interior under the inclusion is open in the ambient space, because the ball is open, and it lies in A_i; so x lies in the interior of A_i.

How this departs from the text's proof. The text moves a point z step by step, each step adding to the set of indices i with $z \notin \Sigma_i$, until z lies in the interior of some Σ_i. The formal proof is the induction on the index set above. Neither uses the Baire property, which a finite union does not need. The lemma is not used by the formal proof of Lemma 15.1.5 (§XV.5); it is formalized as stated.

XV.5 Lemma 15.1.5 (2017: 15.2): local dichotomy of finitely many maps

Statement (stronger) `Chapter15/SeparationLemmas · Linearization15.lemma_15_1_5`. In a pseudo-metric space, let s_i, $i \in I$ finite, be maps continuous on a ball $B_\varepsilon(y)$, $\varepsilon > 0$, with values in a Hausdorff space. Then there are z with $d(z, y) < \varepsilon$, $\delta > 0$ and a surjective partition $e : I \to \{1, \dots, p\}$ such that (1) $B_\delta(z) \subseteq B_\varepsilon(y)$, (2) $s_i = s_{i'}$ on $B_\delta(z)$ when $e(i) = e(i')$, and (3) $s_i(w) \neq s_j(w)$ for $w \in B_\delta(z)$ when $e(i) \neq e(j)$. The text (pp. 685–686) states it for the sections of a local sc$^+$-section structure on O; the formal maps need only be continuous, with no linear or sc-structure.

The topological form `Chapter15/SeparationLemmas · Linearization15.exists_isOpen_dichotomy`: for finitely many maps continuous on a nonempty open set V of a topological space, with values in a Hausdorff space, there is a nonempty open $W \subseteq V$ on which every pair of maps either coincides everywhere or differs everywhere.

Proof. By induction over a finite set S of pairs (i, j), the claim being that some nonempty open $W \subseteq V$ has the dichotomy for the pairs in S. For $S = \emptyset$ take $W = V$. For the step, let W serve the pairs of S and add the pair (i, j). The map $w \mapsto (s_i(w), s_j(w))$ is continuous on W, and the complement of the diagonal is open because the target is Hausdorff, so

$$W' = \{w \in W : s_i(w) \neq s_j(w)\}$$

is open. If W' is empty, then $s_i = s_j$ on W, and W serves $S \cup \{(i, j)\}$. If W' is nonempty, then W' serves the new pair (the maps differ everywhere on it) and still serves the pairs of S, since coincidence

or difference everywhere on W passes to the subset W'. Applying this to the set of all pairs gives the claim.

The lemma from the topological form. Apply it to the ball, open and nonempty: it gives W and a point $z \in W$; $d(z, y) < \varepsilon$ since W lies in the ball. As W is open, some $B_\delta(z) \subseteq W$, which gives (1). The partition is that of the values at z `Chapter15/SeparationLemmas · Linearization15.exists_fin_partition`: $e(i) = e(j)$ iff $s_i(z) = s_j(z)$. For (2), if $e(i) = e(i')$ the pair cannot differ everywhere on W (it agrees at z), so it coincides on $W \supseteq B_\delta(z)$. For (3), if $e(i) \neq e(j)$ the pair cannot coincide on W (it differs at z), so it differs everywhere on W.

How this departs from the text's proof. The text builds the pieces one at a time: it fixes i_1, considers the closed sets $\Sigma_j = \{s_j = s_{i_1}\}$, uses Lemma 15.1.4 when they cover the ball, moves the point slightly, and repeats with $i_2 \notin I_1$ on a ball of a quarter of the radius. The formal proof goes through the pairs instead of the pieces and shrinks the open set at each step to where the new pair differs, if that set is not empty. The argument for a single pair is the one observation that the set where two continuous maps into a Hausdorff space differ is open; if it is empty on an open set, the maps agree there. So Lemma 15.1.4 is not needed. The same form gives the locally dichotomous points used in §§XV.3, XV.6 and XV.7 `Chapter15/SeparationLemmas · Linearization15.exists_isLocDich_mem`.

XV.6 Remark 15.1.6: modifying the sequence

The remark, new in the 2021 edition (p. 686), makes two observations: a sequence with the properties of Proposition 15.1.3 can be obtained from any sequence $x'_k \to 0$ by modifying it "slightly" and passing to a subsequence; and modifying such a sequence slightly keeps the properties. Both are formalized, with "slightly" made explicit (restated).

First part `Chapter15/SeparationLemmas · Linearization15.remark_15_1_6`. In a metric space, for finitely many maps continuous on an open V with values in a Hausdorff space and any sequence $x'_k \to x_0$ in V, there are $x''_k \in V$ with $d(x'_k, x''_k) < 1/(k+1)$ and $x''_k \to x_0$, a strictly increasing ϕ, and a partition e with the separation property at every $x''_{\phi(k)}$. *Proof.* For each k the set $B_{1/(k+1)}(x'_k) \cap V$ is open and nonempty (it contains x'_k), so it contains a locally dichotomous point x''_k (§XV.3, Step 1). Then $d(x''_k, x_0) \le d(x''_k, x'_k) + d(x'_k, x_0)$, and both terms tend to 0, the first being below $1/(k+1)$; by squeezing, $x''_k \to x_0$. The subsequence and the partition come from the pigeonhole step of §XV.3 `Chapter15/SeparationLemmas · Linearization15.exists_isSeparatedAt_subseq`. "Slightly" is the bound $1/(k+1)$, which gives the text's $d(x'_k, x''_k) \to 0$. The modified points need not differ from x_0; if $x'_k \neq x_0$ is wanted as well, one removes x_0 from the open sets as in §XV.3.

Second part `Chapter15/SeparationLemmas · Linearization15.IsSeparatedAt.eventually`. If the separation property holds at z for a partition e and the maps are continuous at z, it holds at every z' in a neighbourhood of z. *Proof*, pair by pair, finitely many conditions each holding on a neighbourhood. For a pair in one piece, $s_i = s_j$ on a neighbourhood N of z; on the open interior of N both clauses hold at every point, (1) because the values agree and (2) because the germs agree. For a pair in different pieces, $s_i(z) \neq s_j(z)$, so $(s_i(z), s_j(z))$ lies off the diagonal, which is closed in a Hausdorff space; by continuity of $w \mapsto (s_i(w), s_j(w))$ at z, the values differ on a neighbourhood, and (1) holds there while (2) is vacuous for the pair. So small moves of the points of a separating sequence keep it separating, which is the text's second observation; "slightly" means "inside this neighbourhood".

XV.7 Proof of Theorem 15.1.1: the core lemma, the model, the chart, the change of chart

The proof follows the text's reduction to a local model and its limit argument, with three changes: the separation runs in the level-1 topology, the two structures are separated together without halving weights, and the formal sums compared are of pairs (value, derivative) over all branches. The steps are (a) a limit lemma for finite formal sums, (b) the comparison at a separated point, (c) the core lemma in a topological space, (d) the model, (e) the chart, (f) the change of chart and the intrinsic statement.

(a) The limit step `Chapter15/SeparationLemmas · Linearization15.wsum_eq_of_frequently`. Let $a_i(z)$, $b_j(z)$ be finitely many points of a Hausdorff space Q, depending on z in a topological space and continuous at x_0, with weights σ_i, τ_j. If the formal sums $\sum \sigma_i \cdot a_i(z)$ and $\sum \tau_j \cdot b_j(z)$ agree for z frequently near x_0 (that is, in every neighbourhood of x_0 there is such a z), they agree at x_0. *Proof.* Fix $q \in Q$. For each point $p \neq q$ choose disjoint neighbourhoods $N_p \ni q$ and $V_p \ni p$ (Hausdorff); for $p = q$ take $N_q = V_q = Q$. Let N_0 be the intersection of the finitely many N_p for p among the values $a_i(x_0)$, $b_j(x_0)$: a neighbourhood of q. For z near x_0, and each i: if $a_i(x_0) = q$, then N_0 is a neighbourhood of $a_i(x_0)$ and $a_i(z) \in N_0$ by continuity; if $a_i(x_0) = p \neq q$, then $a_i(z) \in V_p$, which is disjoint from $N_p \supseteq N_0$. So eventually $a_i(z) \in N_0 \iff a_i(x_0) = q$, for all i, and likewise for the b_j. Choose z with this property at which the two formal sums agree. Then the mass of N_0 under the first sum at z is the coefficient of q in the first sum at x_0, the mass under the second is that of the second, and the two masses are equal because the formal sums at z are (§XV.1) `Chapter15/SeparationLemmas · Linearization15.mass_eq_of_wsum_eq`. This is the text's convergence "in the weak topology" of the formal sums: the points cluster near their limits, and a neighbourhood that separates one limit from the others carries the limit's coefficient.

(b) At a locally dichotomous point `Chapter15/SeparationLemmas · Linearization15.wsum_pair_eq_at_of_isLocDich`. Let the branches c_α, $\alpha \in I \sqcup K$, of two families with weights σ on I and τ on K give the same weighted count of every value at u, let u be locally dichotomous for the combined family, and let the "derivatives" $D_\alpha(u)$ depend only on germs: $c_\alpha = c_\beta$ near u implies $D_\alpha(u) = D_\beta(u)$. Then the formal sums of the pairs $(c_\alpha(u), D_\alpha(u))$ over I and over K agree. *Proof.* Fix a pair (v, L). Two branches through v at u cannot differ at u, so by dichotomy they coincide near u, and by locality they have the same D. Hence there is one L_v with $D_\alpha(u) = L_v$ for every branch through v (any L if there is none). For such a family, the coefficient of (v, L) is the coefficient of v if $L = L_v$ and 0 otherwise `Chapter15/SeparationLemmas · Linearization15.wsum_pair_of_const`: the pairs with first entry v are exactly (v, L_v). Applying this to both families, with the same L_v since it was chosen for the combined family, the coefficients are the counts of v, which agree.

(c) The core lemma `Chapter15/SeparationLemmas · Linearization15.wsum_pair_eq_of_isLocal`. Let both families be continuous on an open V, with equal weighted counts of every value at every point of V, and let the D_α be continuous on V and depend only on germs at every point of V. Then at every $x_0 \in V$ the formal sums $\sum \sigma_i \cdot (c_i, D_i)(x_0)$ and $\sum \tau_j \cdot (c_j, D_j)(x_0)$ agree. *Proof.* The maps $z \mapsto (c_\alpha(z), D_\alpha(z))$ are continuous at x_0, so the limit step (a) applies once the sums agree frequently near x_0. Given a neighbourhood N of x_0, the set $\mathrm{int}(N) \cap V$ is open and contains x_0, so it contains a point u locally dichotomous for the combined family (§XV.3, Step 1); by (b) the sums agree at u. *Departure from the text.* The text forms the union of the two structures with halved weights, applies Proposition 15.1.3 to it, and compares multiplicities piece by piece along the sequence. Here the dichotomy is applied to the combined family $I \sqcup K$ directly, which needs no new structure and no weights. The points u may include x_0 itself, so no sequence $x_k \neq x_0$ is needed and isolated points are covered; this is why Proposition 15.1.3 is not used and its failure at isolated points (§XV.3) does not reach the theorem.

(d) On the model. Two facts of the sc-calculus at level 1 come first. *Continuity of values* `Chapter15/LinearizationModel · Linearization15.continuousOn_comp_toBase_one`: an sc^0 map is continuous on U_1 in the level-1 topology, read in F_0 (it is continuous $U_1 \to F_1$, and $F_1 \to F_0$ is continuous). *Continuity of derivatives* `Chapter15/LinearizationModel · Linearization15.continuousOn_scDeriv_coe`: for an sc^1 map g, $u \mapsto Dg(u)$ is continuous on U_1 (level-1 topology) into the operators $E_0 \to F_0$ with the topology of pointwise convergence. This is Definition 1.1.15 (3), the continuity of $(u,h) \mapsto Dg(u)h$ on $U_1 \times E_0$, read one h at a time. *Locality of the derivative* `Chapter15/LinearizationModel · Linearization15.scDeriv_eq_of_eventuallyEq_lvl`: if two sc^1 maps g, g' on an sc-domain agree near a level-1 point x in the level-1 topology, then $Dg(x) = Dg'(x)$. Both derivatives are Fréchet derivatives of $g \circ \iota$, $g' \circ \iota$ within U_1 at x; the two composites agree near x within U_1, so they have the same derivatives there, and within an sc-domain the derivative within U_1 is unique; finally an operator on E_0 is determined by its values on the dense E_1.

The comparison on the model `Chapter15/LinearizationModel · Linearization15.wsum_model_eq`. Let the two structures have the same counts at every $y \in O \cap N$. Work on the space $Z = U_1$, the level-1 points of U with the level-1 topology, and on its open subset $V = \{u : r(u) \in N\}$, open because $u \mapsto r(u)$ is continuous on U_1 (r is sc-smooth, so sc^0). The combined family has branches $c_\alpha(u) = \hat{s}_\alpha(r(u))$ (the $\hat{s}_i$ and the $\hat{t}_j$ together) and derivatives $D_\alpha(u) = D((\hat{f} - \hat{s}_\alpha) \circ r)(u)$, regarded as functions $E_0 \to F_0$. The hypotheses of the core lemma hold. Continuity: the c_α by the first fact, since $\hat{s}_\alpha \circ r$ is sc-smooth; the D_α by the second, since $(\hat{f} - \hat{s}_\alpha) \circ r$ is sc-smooth, a difference of sc-smooth maps. Counts: at $u \in V$ they are the counts at $r(u) \in O \cap N$, equal by hypothesis. Locality: if $c_\alpha = c_\beta$ near u in U_1, then $(\hat{f} - \hat{s}_\alpha) \circ r$ and $(\hat{f} - \hat{s}_\beta) \circ r$ agree near u in U_1 (both are $\hat{f} \circ r$ minus the branch), so their derivatives agree at u by the locality fact. The core lemma gives equal formal sums of pairs at the point z, which lies in U_1 because it lies over $O \subseteq U$, and in V because $r(z) = z$ for $z \in O$.

Theorem 15.1.1 on the model, from the pairs. The coefficient of an operator $\ell : T_zO \to F_0$ in the formal sum of a structure is the mass, under the formal sum of pairs, of the set

$$N_\ell = \{(v, D) : v = \hat{f}(z),\ D(h) = \ell(h) \text{ for all } h \in T_zO\}.$$

Indeed, the summand i contributes σ_i iff $\hat{s}_i(z) = \hat{f}(z)$ and $(\hat{f} - \hat{s}_i)'(z) = \ell$, and the latter, an equality of operators on T_zO, says that the full derivative $D((\hat{f} - \hat{s}_i) \circ r)(z)$ agrees with ℓ on T_zO, which is the membership of the pair in N_ℓ (with $r(z) = z$). Equal formal sums of pairs give equal masses (§XV.1), so the coefficients of ℓ agree for the two structures; this proves `theorem_15_1_1_model`. The form with an arbitrary map ψ of operators is the same argument with the set $\{(v, D) : v = \hat{f}(z),\ \psi(L) = q' \text{ for every operator } L \text{ with } L = D\}$: the derivative is recorded as a function, and ψ is applied to the operator it determines.

Two readings of the text's proof (Findings, Chapter 15, items 1 and 2). (a) The text takes the points x_k of Proposition 15.1.3 in the metric of E_0 and lets $T(f - s_i)(x_k)$ converge "in the weak topology". The derivative of an sc^1 map is continuous only on level 1, and there only pointwise as an operator $E_0 \to F_0$. So the separation is run in the level-1 topology, where the branches are continuous and the separation lemmas hold equally (they are topological), and the "weak topology" is read as pointwise convergence of operators, which is the topology in which the derivatives are continuous. (b) The last display of the text sums $\sigma_i \cdot T(f - s_i)(0)$ over all i and then uses $f(0) = s_i(0)$; this holds only for some i, and the sum is presumably over $\{i : f(0) = s_i(0)\}$. The formal proof compares the formal sums of the pairs $(s_i, (f - s_i)')$ over all i, where no such equation is needed, and selects the first entry $f(0)$ only at the end, by the mass of N_ℓ.

(e) In a strong bundle chart. Let c be a strong bundle chart of P with base chart φ, model O and fibre model F, and let s be a section over $O_X \supseteq \mathrm{dom}(c)$. Its principal part $\hat{s}$ is the fibre component of $c \circ s \circ \varphi^{-1}$: $c(s(\varphi^{-1}(z))) = (z, \hat{s}(z))$ for $z \in O$ `Chapter15/Linearization · SBLocalization.apply_localSection`. *Principal parts are sc-smooth.* A local sc⁺-section on O_X has $\hat{s} \circ r$ sc-smooth on U in every chart of the atlas with domain in O_X `Chapter15/Linearization · SBLocalization.IsScPlusSectionOn.isScSmooth_principal_comp_r`. The sc⁺-section is an sc-smooth map into $W_{0,1}$; composed with the sc-smooth inclusion $W_{0,1} \to W$ it is sc-smooth into W on O_X; read in the chart, $z \mapsto (z, \hat{s}(z))$ is an sc-smooth retract map $O \to K$; composed with the base retraction $r : U \to O$ and projected to the second factor, $\hat{s} \circ r$ is sc-smooth. The same holds for an sc-smooth global section `Chapter15/Linearization · SBLocalization.isScSmooth_principal_comp_r`. *Counts in the chart* `Chapter15/Linearization · SBLocalization.IsLocalRepOn.count_eq`: for a local section structure of Λ on $O_X \supseteq \mathrm{dom}(c)$ and $y \in O$, the weighted count $\sum_{i:\hat{s}_i(y)=v} \sigma_i$ equals $\Lambda(\Phi^{-1}(y, v))$ if $(y, v) \in K$, and 0 otherwise. If $(y, v) \in K$, let $w = \Phi^{-1}(y, v)$, which lies over $\varphi^{-1}(y) \in O_X$; the defining formula of the structure gives $\Lambda(w) = \sum_{i:w=s_i(Pw)} \sigma_i$, and $w = s_i(\varphi^{-1}(y))$ iff $\hat{s}_i(y) = v$, by injectivity of the chart and the formula for $\hat{s}_i$. If $(y, v) \notin K$, no branch can have $\hat{s}_i(y) = v$, since $(y, \hat{s}_i(y))$ is the chart image of $s_i(\varphi^{-1}(y))$ and lies in K. *The statement in a chart* `Chapter15/Linearization · SBLocalization.linSumChart_eq`: for two structures of Λ on O and O' and a chart with domain in $O \cap O'$, both counts at every y of the model equal $\Lambda(\Phi^{-1}(y, v))$ or 0, so the model theorem applies with N the whole space; Theorem 15.1.1 in a chart is this for sc-Fredholm section functors, which are sc-smooth `Chapter15/Linearization · SBLocalization.theorem_15_1_1`. Every object lies in such a chart `Chapter15/Linearization · SBLocalization.exists_chart_isLocalRepOn`: an sc⁺-multisection has a local section structure on the domain $U(x)$ of a natural representation around x, and any atlas chart around x restricted to its domain intersected with $U(x)$ is a chart with domain in $U(x)$.

(f) The change of chart, and the statement with intrinsic operators. *Independence of the structure in* $\mathrm{GrF}(x)$ `Chapter15/LinearizationIntrinsic · SBLocalization.linSumIntr_eq_of_isLocalRepOn`: in one chart with domain in $O \cap O'$, the intrinsic formal sums of two structures agree. This is the model theorem with the map ψ that sends a chart operator to its intrinsic operator (§XV.1), at the level-1 point over $\varphi(x)$, with the counts of (e).

The text's "without loss of generality $X = O$" is, formally, the independence of the intrinsic operator $(f - s)'(x)$ from the chart. The proof makes $f - s$ a global section to which Part I's chain rule applies. *The section $f - s$ on O_X* `Chapter15/LinearizationIntrinsic · SBLocalization.sectionSubOn`: at $y \in O_X$ the difference $f(y) - s(y)$ in the fibre, and $f(y)$ elsewhere; a section `Chapter15/LinearizationIntrinsic · SBLocalization.isSection_sectionSubOn` whose principal part in a chart with domain in O_X is $\hat{f} - \hat{s}$ `Chapter15/LinearizationIntrinsic · SBLocalization.principal_sectionSubOn`, because the chart is linear on fibres. In such a chart $z \mapsto (z, \hat{f}(z) - \hat{s}(z))$ is an sc-smooth retract map $O \to K$ `Chapter15/LinearizationIntrinsic · SBLocalization.isScSmoothRetractMap_sectionSubOn`: for every sc-smooth retraction R' onto O, $\hat{f} \circ R'$ and $\hat{s} \circ R'$ are sc-smooth (as in (e)), and so is the pair $(R', \hat{f} \circ R' - \hat{s} \circ R')$; this is the chart-wise form of sc-smoothness that Part I's statements take. The derivative of $(\hat{f} - \hat{s}) \circ r$ at a level-1 point equals that of the principal part of $f - s$ composed with r `Chapter15/LinearizationIntrinsic · SBLocalization.scDeriv_sub_eq_sectionSubOn`, since the two maps agree on U (derivatives of sc¹ maps agreeing on a relatively open set agree on its level-1 points).

The values lie in the fibre `Chapter15/LinearizationIntrinsic · SBLocalization.chartOp_mem_range`. At a zero x of a global section g whose principal part is sc-smooth in the chart, every value $D(\hat{g} \circ r)(z)(T\varphi\,\alpha)$ lies in $\Phi_x(W_x)$. Part I's lemma on the derivative at a zero `Chapter3/LinearizationCharts · rho_scDeriv_comp_r` says that the bundle projection $\rho(z)$ onto the fibre K_z fixes $D(\hat{g} \circ r)(z)$ on T_zO when $\hat{g}(z) = 0$; so the values

lie in $K_z = \Phi_x(W_x)$. Hence the default branch of the intrinsic operator is never taken at the points of interest.

The chain rule `Chapter15/LinearizationIntrinsic · SBLocalization.toIntr_chart_independent`. At a zero $x \in X_1$ of a section g whose principal parts are sc-smooth in two charts c, c' around x, the intrinsic operators through c and through c' are equal. Part I's chain rule with the operators named `Chapter3/LinearizationChartChange · linAt_chart_change_key` provides a retraction r_W onto the base overlap and the identity

$$D(\hat{g}' \circ r')(z')(D(\tau \circ r_W)(z)v) = \Gamma(z)(D(\hat{g} \circ r)(z)v),$$

with τ the base transition and $\Gamma(z)$ the fibre transition operator. Two further identities translate this to intrinsic operators: the chart vector of $\alpha \in T_xX$ in c' is $D(\tau \circ r_W)(z)$ applied to its chart vector in c (the transition of tangent fibres), and the fibre part of c' is $\Gamma(z)$ composed with that of c. With these, Φ'_x applied to the operator through c' equals Φ'_x applied to the operator through c, and Φ'_x is injective. This is the argument of Part I's chart independence of $f'(x)$ `Chapter3/LinearizationIntrinsic · StrongBundle.linIntr_chart_independent`, with chart-wise hypotheses only, so that it applies to $f - s$, which is sc-smooth only over O_X.

The formal sum does not depend on the chart `Chapter15/LinearizationIntrinsic · SBLocalization.linSumIntr_chart_independent`. For one structure on O_X and two charts with domains in O_X, the formal sums agree term by term. The selection condition is the same through both charts: $\hat{s}_i(\varphi(y)) = \hat{f}(\varphi(y))$ iff $s_i(y) = f(y)$ `Chapter15/LinearizationIntrinsic · SBLocalization.principal_eq_iff`, by injectivity of the chart on the fibre. For a selected i, the operator $(f - s_i)'(x)$ through either chart is the intrinsic operator of the global section $f - s_i$ at its zero x (by the derivative identity above), and the chain rule gives equality.

Proof of the intrinsic statement. Given structures on O, O' and charts c, c' with domains in O, O' around $x \in X_1$, let c'' be c restricted to $\mathrm{dom}(c) \cap O \cap O'$, a chart around x with domain in $O \cap O'$. Then: the sum of (s, σ) through c equals that through c'' (chart independence, structure s); through c'' it equals the sum of (t, τ) (independence of the structure); and that equals the sum of (t, τ) through c' (chart independence, structure t). Only the sc-smoothness of f enters; the theorem is stated for sc-Fredholm section functors, as in the text.

XV.8 Definition 15.1.7 (2017: 15.1): the linearization $T(f, \Lambda)$

Definition (restated) `Chapter15/LinearizationIntrinsic · SBLocalization.linearization`. *Local data* at $x \in X_1$ `Chapter15/LinearizationIntrinsic · SBLocalization.LocalLinData` are an open set O, a local sc⁺-section structure $(s_i, \sigma_i)_{i<k}$ of Λ on O, and a strong bundle chart c of the atlas around x with domain in O; their formal sum is the intrinsic sum through c `Chapter15/LinearizationIntrinsic · SBLocalization.LocalLinData.sum`. $T(f, \Lambda)(x) \in \mathrm{GrF}(x)$ is the sum of some local data, chosen, and 0 if there are none. The text calls $T(f, \Lambda)$ the linearization of $\Lambda \circ f$ "at the points in $\mathrm{supp}(\Lambda \circ f)$" (p. 687); the formal definition is made at every level-1 point, with value 0 off the support (§XV.2).

Well-defined `Chapter15/LinearizationIntrinsic · SBLocalization.LocalLinData.sum_eq`: any two local data at x give the same sum, by the intrinsic Theorem 15.1.1 (§XV.7 (f)). **Data exist** `Chapter15/LinearizationIntrinsic · SBLocalization.nonempty_localLinData` at every level-1 point of an sc⁺-multisection, from the chart of §XV.7 (e). **Theorem 15.1.1 (2)** `Chapter15/LinearizationIntrinsic · SBLocalization.linearization_eq`: $T(f, \Lambda)(x)$ is the sum of *any* local data at x; so the value at y may be computed from any structure around x and any chart around y with domain inside it, which is the

text's (2) for all y near x, smooth or of level 1. **Theorem 15.1.1 (1) and Remark 15.1.2** Chapter15/LinearizationIntrinsic · SBLocalization.linearization_eq_zero: where $\Lambda(f(x)) = 0$, $T(f,\Lambda)(x) = 0$. *Proof.* Take the chosen data (O, s, σ, c). The point $(\varphi(x), \widehat{f}(\varphi(x)))$ lies in K, and Φ^{-1} of it is $f(x)$; so by the count formula (§XV.7 (e)) the weighted count of $\widehat{f}(\varphi(x))$ is $\Lambda(f(x)) = 0$. With positive weights, no branch has $\widehat{s}_i(\varphi(x)) = \widehat{f}(\varphi(x))$, and every summand of the formal sum vanishes.

In a chart. The formalization also keeps the chart-level definition: in a chart c, the formal sum of any structure on an open set containing the domain of c, and 0 if there is none Chapter15/Linearization · SBLocalization.linearizationIn, equal to the sum of every such structure at every level-1 point Chapter15/Linearization · SBLocalization.linearizationIn_eq, and 0 where $\Lambda(f(y)) = 0$ Chapter15/Linearization · SBLocalization.remark_15_1_2. It is the form used where an argument stays inside one chart.

The definition is the value of a section; that this section is a *functor* is the next subsection.

XV.9 Theorem 15.1.1: the functor property

The text calls $T(f,\Lambda)$ a section functor of $\mathrm{GrF}(X) \to X_\infty$, i.e. $T(f,\Lambda)(t(\varphi)) = \varphi_* T(f,\Lambda)(s(\varphi))$ for every morphism, and gives no separate argument for it. The formalization proves it at every level-1 point (stronger than the text's smooth points), with no added hypothesis.

The action of a morphism on GrF**.** For $\varphi : x \to y$, $\mu(\varphi,\cdot) : W_x \to W_y$ is a linear map Chapter15/LinearizationFunctor · SBLocalization.muLin Chapter15/LinearizationFunctor · SBLocalization.muLin_apply, linear because the action of a strong bundle over an ep-groupoid is linear on fibres. If x is of level 1 then so is φ Chapter15/LinearizationFunctor · SBLocalization.mem_levelSet_one_of_src (a morphism lies in $\mathbf{X}_m$ iff its source lies in X_m), and then Chapter 7's tangent map $T\varphi : T_xX \to T_yX$ is a bounded linear isomorphism Chapter7/TangentMorphismLinear · EpGroupoid.tangentMorCLE. An operator $L : T_xX \to W_x$ is carried to

$$\varphi_* L = \mu(\varphi,\cdot) \circ L \circ (T\varphi)^{-1} : T_yX \to W_y$$

Chapter15/LinearizationFunctor · SBLocalization.conjOp Chapter15/LinearizationFunctor · SBLocalization.conjOp_apply, which is the text's $\varphi_* L \circ T\varphi = \mu(\varphi, L(\cdot))$, and a formal sum to the push-forward of its coefficients along $L \mapsto \varphi_* L$ Chapter15/LinearizationFunctor · SBLocalization.grfPush.

Statement (stronger, for this clause) Chapter15/LinearizationFunctor · SBLocalization.theorem_15_1_1_functor. For an sc-Fredholm section functor f, an sc$^+$-multisection Λ, a morphism φ and level-1 points $x = s(\varphi)$, $y = t(\varphi)$: $T(f,\Lambda)(y) = \varphi_* T(f,\Lambda)(x)$ in $\mathrm{GrF}(y)$.

Proof. Since $T(f,\Lambda)(y)$ may be computed from *any* local data at y (§XV.8), it suffices to carry local data at x to local data at y and to compare the two sums. The carrying uses the local strong bundle isomorphism attached to a morphism by its sheet, built in Chapter 12 (Part XII) Chapter12/MorphismIso · EpStrongBundle.morIso: over the image $t(\text{sheet})$ of the sheet of φ it consists of the base sc-diffeomorphism $\phi = s \circ (t|_{\text{sheet}})^{-1}$ onto $s(\text{sheet})$, with $\phi(y) = x$, and the fibre maps Φ, Ψ given by the action μ of the morphisms of the sheet.

Step 1, data at x inside the sheet. Take local data (O, s, σ, c) at x, restrict the chart to $\mathrm{dom}(c) \cap s(\text{sheet})$ and the structure to $O \cap s(\text{sheet})$ (a local structure restricts to open subsets Chapter11/MultisectionLocalStructure2021 · SBLocalization.IsLocalRepOn.mono). Call the result (O, s, σ, c) again.

Step 2, carrying the sections Chapter15/LinearizationFunctor · SBLocalization.transSec. A section s near x becomes $z \mapsto \Psi(s(\phi(z)))$ on $t(\text{sheet}) \cap \phi^{-1}(O)$ Chapter15/LinearizationFunctor · SBLocalization.transSet, an

open set Chapter15/LinearizationFunctor · SBLocalization.isOpen_transSet (the preimage of an open set under the continuous ϕ), and the carried section is a section there Chapter15/LinearizationFunctor · SBLocalization.P_transSec because Ψ covers ϕ^{-1}. An sc⁺-section stays sc⁺ Chapter15/LinearizationFunctor · SBLocalization.isScPlusSectionOn_transSec: its level-1 lift is the composite of the lift of s with ϕ and with the level-1 part of Ψ, all sc-smooth. A local section structure of a *functor* Λ is carried to one of Λ, with the same weights Chapter15/LinearizationFunctor · SBLocalization.isLocalRepOn_transSec: for w over the new domain, $\Lambda(w) = \Lambda(\Phi(w))$ because Φ acts by μ of a morphism and Λ is a functor Chapter15/LinearizationFunctor · SBLocalization.isWFunctor_morIso_Φ; the formula of the structure at $\Phi(w)$, which lies over $\phi(P(w)) \in O$, counts the i with $\Phi(w) = s_i(\phi(Pw))$; and this holds iff $w = \Psi(s_i(\phi(Pw)))$, since Φ and Ψ are inverse on the relevant fibres.

Step 3, carrying the chart. The chart c at x is carried to the transported chart $c \circ \Phi$ at y Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.transportChart, with base chart $\varphi \circ \phi$ and the same model; it is a chart of the atlas Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.isChart_transportChart. In it the principal parts of the carried sections are those of the given sections in c Chapter15/LinearizationFunctor · SBLocalization.principal_transportChart_transSec (unwind $\Phi \circ \Psi = \mathrm{id}$ and $\phi \circ \phi^{-1} = \mathrm{id}$), and the principal part of f is that of f in c Chapter3/FredholmPullbackIso · StrongBundle.LocalIso.principal_transportChart, because a functorial section satisfies $f = \Psi \circ f \circ \phi$ on $t(\text{sheet})$ Chapter12/MorphismIso · EpStrongBundle.eqOn_morIso, which is $f(t(\psi)) = \mu(\psi, f(s(\psi)))$ for the morphisms ψ of the sheet.

Step 4, the chain rule in the carried chart. Two identities at the point. $T\varphi$ is the identity on chart vectors Chapter15/LinearizationFunctor · SBLocalization.chartVec_transport: the chart vector of $T\varphi(\beta)$ in $c \circ \Phi$ equals the chart vector of β in c. Indeed $T\varphi = T\hat{\varphi}$ at x (Chapter 7's tangent map of a morphism is that of the local diffeomorphism $\hat{\varphi} = t \circ (s|_{\text{sheet}})^{-1}$), $T(\phi) \circ T(\hat{\varphi}) = \mathrm{id}$ near x since $\phi \circ \hat{\varphi} = \mathrm{id}$, and the chart vector of $Tg(\alpha)$ in c is that of α in $c \circ g$. And $\mu(\varphi, \cdot)$ followed by the fibre part of the carried chart at y is the fibre part of c at x Chapter15/LinearizationFunctor · SBLocalization.fiberLin_transport_muLin, because on W_x the fibre map Ψ is $\mu(\varphi, \cdot)$ and Φ undoes it; also the fibre part of the carried chart at y takes values in that of c at x Chapter15/LinearizationFunctor · SBLocalization.fiberLin_transport_mem_range. Together Chapter15/LinearizationFunctor · SBLocalization.toIntr_transportChart: for every chart operator L, the intrinsic operator through the carried chart is $\mu(\varphi, \cdot) \circ (\text{intrinsic operator through } c) \circ (T\varphi)^{-1}$. If the values of $L \circ T\varphi$ lie in the fibre for c, those through the carried chart lie in the fibre (the preimages are the $\mu(\varphi, \cdot)$-images), and the two sides agree after applying the injective fibre part; if not, neither do the carried ones, and both sides are 0.

Step 5, the sums correspond Chapter15/LinearizationFunctor · SBLocalization.linSumIntr_transportChart. The level-1 point of the carried chart over y is the level-1 point of c over x, since $\phi(y) = x$. Term by term: the selection condition is the same (the principal parts agree), and the derivative $D((\hat{f} - \hat{s}_i) \circ r)(z)$ is the same in both charts, the composites agreeing on U. So each term of the sum at y is φ_* of the corresponding term at x by Step 4, and push-forward of formal sums is additive. With the carried data at y and the given data at x, §XV.8 identifies both sides with $T(f, \Lambda)(y)$ and $\varphi_* T(f, \Lambda)(x)$.

Not formalized. That $\varphi \mapsto \varphi_*$ is itself functorial, $(\psi\varphi)_* = \psi_*\varphi_*$ and $1_* = \mathrm{id}$, which the text uses to speak of $\mathrm{GrF}(X)$ as a category, is not formalized and not needed for the theorem; it would follow from Chapter 7's functoriality of T and the composition law of μ, in about 60–100 lines.

XV.10 Local sc⁺-sections, the sections $f - s_i$ on $W|_O$, and local solution sets (prerequisite for §15.2)

The proofs of Theorems 15.2.2 and 15.2.5 and of the sc-Fredholm property of the summands (§XV.11) apply Part I's implicit function theorem to $f - s_i$ near x, where s_i is defined only on an open O. The formalization makes $f - s_i$ a section problem of Part I on the restricted strong bundle $W|_O$ (extra).

Local sc⁺-sections in compatible charts. Chapter 11 defines a local sc⁺-section on O as a section over O that is sc-smooth into $W_{0,1}$. Two chart facts are needed for charts that are only compatible with the atlas, such as restricted charts. In every such chart with domain in O, the principal part takes values in F_1 `Chapter15/LocalScPlus · SBLocalization.IsScPlusSectionOn.principal_mem_range_of_isChart`: compare with an atlas chart around $s(x)$, in which this holds by Chapter 13's local form `Chapter13/ScPlusSectionOn · SBLocalization.IsScPlusSectionOn.isScSmoothRetractMap_localRepOne`, through the transition, which preserves level 1 in the fibre. And the level-1 representative $z \mapsto (z, \hat{s}_1(z))$ `Chapter15/LocalScPlus · SBLocalization.localRepOne_eq_of_sub` is an sc-smooth retract map $O \to K[1]$ `Chapter15/LocalScPlus · SBLocalization.IsScPlusSectionOn.isScSmoothRetractMap_localRepOne_of_isChart`. The proof is local: near each point, the representative is the composite of the base transition into an atlas chart c' around $s(x)$, the representative in c' (sc-smooth by Chapter 13), and the level-1 part of the bundle transition back to c; the composite agrees with the representative on the overlap.

Restriction to O `Chapter15/LocalScPlus · SBLocalization.IsScPlusSectionOn.restrictOpen`. A local sc⁺-section on O is a global sc⁺-section of the restricted strong bundle $W|_O$, Part I's pull-back along the inclusion $O \to X$ `Chapter3/RestrictOpen · StrongBundle.restrictOpen`: the charts of $W|_O$ are restrictions of charts with domain in O, and in them the two chart facts above are the conditions of an sc⁺-section. (The restricted bundle needs the paracompactness of O and of the pulled-back total space as type-class data; they hold for open subsets of M-polyfolds and are supplied in the proofs.)

The section $f - s$ `Chapter15/LocalScPlus · SBLocalization.subSec`: $f + (-1) \cdot \bar{s}$, where $\bar{s}$ is s extended by 0 off O; a global section `Chapter15/LocalScPlus · SBLocalization.isSection_subSec` with principal part $\hat{f} - \hat{s}$ in every chart with domain in O `Chapter15/LocalScPlus · SBLocalization.principal_subSec` and with zeros in O exactly where $f = s$ `Chapter15/LocalScPlus · SBLocalization.isZeroAt_subSec_iff`. Its restriction to $W|_O$ `Chapter15/LocalScPlus · SBLocalization.subRestrict` is a tame sc-Fredholm section when f has Part I's tame germ data `Chapter15/LocalScPlus · SBLocalization.isScFredholmSectionTame_subRestrict`. *Proof.* Restriction to an open set keeps tame germ data (Part I), so $f|_O$ is tame sc-Fredholm on $W|_O$; $-\bar{s}$ is an sc⁺-section on O (Chapter 13: sc⁺-sections on O are closed under constant multiples), hence a global sc⁺-section of $W|_O$ by the restriction above; and an sc⁺-perturbation of a tame sc-Fredholm section is one, by Part I's Theorem 3.1.18 in its tame form `Chapter3/TameGermsAddG · theorem_3_1_18_tame`. Finally, the restriction of a sum of sections is the sum of the restrictions.

The linearization in a chart. At a level-1 point z of a chart with domain in O, the chart operator of $(f - s)'$ is $D((\hat{f} - \hat{s}) \circ r)(z) : E_0 \to F_0$ `Chapter15/LocalIFT · SBLocalization.subDeriv`, the derivative of an sc¹ map `Chapter15/LocalIFT · SBLocalization.isSc1_sub_comp_r`, and "onto" means that it maps T_zO onto the fibre $K_z = \{k : (z,k) \in K\}$ `Chapter15/LocalIFT · SBLocalization.ChartOnto`, Part I's "$f'(x)$ onto" read in the chart. *The intrinsic and the chart readings agree* `Chapter15/LocalIFT · SBLocalization.surjective_toIntr_subDeriv_iff`: at $x \in X_1$ with $f(x) = s(x)$, the intrinsic operator $(f - s)'(x) : T_xX \to W_x$ of §XV.1 is onto iff the chart operator maps T_zO onto K_z, z over $\varphi(x)$. The chart operator equals that of the global section $f - s$, whose values at its zero lie in the fibre (§XV.7 (f)); the fibre part of the chart maps W_x bijectively onto $K_{\varphi(x)}$, and $T\varphi$ maps T_xX onto T_zO, so surjectivity transfers in both directions. *And they are Part*

I's surjectivity on $W|_O$. In the restricted chart of $W|_O$ the principal part of $(f-s)|_O$ composed with r has the same derivative as $(\widehat{f}-\widehat{s})\circ r$ `Chapter15/LocalIFT · SBLocalization.scDeriv_restrictTo_subRestrict`; so chart surjectivity gives Part I's surjective linearization of $(f-s)|_O$ at x `Chapter15/LocalIFT · SBLocalization.isLinSurjAt_subRestrict`, and conversely, at a zero, Part I's surjectivity gives chart surjectivity in every chart with domain in O and at every level-1 point over $\varphi(x)$ `Chapter15/LocalIFT · SBLocalization.chartOnto_of_isLinSurjAt_subRestrict`, by the chart independence of Part I's notion.

Local solution sets. *At a point of good position* `Chapter15/LocalIFT · SBLocalization.exists_solutionSet_of_isGoodPosition`. If $(f-s)|_O$ is in good position at x in the sense of Part I's Definition 3.6.6 in a tame chart, there is an open $V \ni x$ inside the domain of c such that $\{y \in V : f(y) = s(y)\}$ is a smooth finite-dimensional submanifold of X (Definition 4.2.1), and at each of its points y: y is smooth, $(f-s)|_O$ is in good position at y, and the chart operator is onto at every level-1 point over $\varphi(y)$. *Proof.* Part I's Theorem 3.6.8 `Chapter3/GlobalIFTNearbyOntoG · theorem_3_6_8'` for the tame sc-Fredholm section $(f-s)|_O$ at its zero x gives an open $V_x \subseteq O$ on which every zero is in good position; on $W = V_x \cap \mathrm{dom}(c)$ the solution set is a smooth submanifold of O by Part I's lemma on solution sets in good position `Chapter5/GeneralPosition · StrongBundle.isSmoothSubmanifold_solutionSet_inter`, and its image under the sc-diffeomorphism $O \to X$ (the inclusion) is a smooth submanifold of X. Zeros of an sc-Fredholm section are smooth points; good position implies surjective linearization; and the converse direction above gives chart surjectivity. *At an interior point* `Chapter15/LocalIFT · SBLocalization.exists_solutionSet_interior`: if $d_X(x)=0$, $f(x)=s(x)$ and the chart operator is onto at x, the same conclusion holds without "good position" in it. The restriction $(f-s)|_O$ has degeneracy index 0 at x (the index of an open subset is that of X), it has surjective linearization at x by the transfer above, and at a point of index 0 Part I's surjectivity gives good position `Chapter3/GlobalIFTIndexG · StrongBundle.isGoodPositionGerm_of_isLinSurjAt`; then the first case applies.

All of this rests on Part I's Theorem 3.6.8 for tame germ data; with the 2021 untamed notion that theorem does not hold as we read it (Part III), which is why f carries the tame germ data here and in §15.2 (§XV.11).

XV.11 Theorem 15.1.1 (2): the summands are sc-Fredholm

The text puts sc-Fredholm operators into $\mathrm{GrF}(x)$ and asserts that $T(f,\Lambda)(x)$ is an element of it: each $(f-s_i)'(x)$ with $f(x)=s_i(x)$ is sc-Fredholm, because $f-s_i$ is an sc$^+$-perturbation of an sc-Fredholm section. The formalization proves this for the operators that occur, in a chart (narrower).

The chart operator is sc-Fredholm `Chapter15/FredholmSummands · SBLocalization.subDeriv_isScFredholm`. Let f have Part I's tame germ data, s be sc$^+$ on an open O containing the domain of the chart c, $f(x)=s(x)$, and z a level-1 point over $\varphi(x)$ in U. Then $D((\widehat{f}-\widehat{s})\circ r)(z)$ is an sc-operator, T_zO and K_z are sc-subspaces, the operator maps T_zO into K_z, and its restriction $T_zO \to K_z$ is sc-Fredholm, Fredholm on every level with the index of level 0. *Proof.* By §XV.10, $(f-s)|_O$ is a tame sc-Fredholm section of $W|_O$ with a zero at x, and the restricted chart of c is a chart of $W|_O$. Part I's statement that the linearization of an sc-Fredholm section at a zero is sc-Fredholm in every chart `Chapter3/LinearizationChartsScG · StrongBundle.linAt_isScFredholm` gives all the conclusions for the derivative of the restricted principal part composed with r, which is $D((\widehat{f}-\widehat{s})\circ r)(z)$ by the derivative identity of §XV.10.

Theorem 15.1.1 (2), the summands (restated, with the inherited hypothesis) `Chapter15/FredholmSummands · SBLocalization.linearization_summand_isScFredholm`. For $x \in X_1$ and any local data (O,s,σ,c) (§XV.8), every operator L in the support of $T(f,\Lambda)(x)$ is $(f-s_i)'(x)$, the intrinsic operator of $D((\widehat{f}-\widehat{s}_i)\circ r)(z)$, for some i with $f(x)=s_i(x)$, and that chart operator is sc-Fredholm as above.

Proof. $T(f,\Lambda)(x)$ is the sum of the given data (§XV.8); an operator in the support of that sum is the intrinsic operator of a branch through $f(x)$ `Chapter15/Transversality · SBLocalization.mem_support_linSumIntr_iff` (positive weights, as in Remark 15.1.2); and the chart statement applies to that branch.

Reading. T_xX and W_x carry no sc-structure in the project: they are a tangent fibre and a fibre with their linear structures. "$(f-s_i)'(x) : T_xX \to W_x$ is sc-Fredholm" is therefore read in a chart, through the identifications $T_xX \cong T_zO$ and $W_x \cong K_z$ by which the intrinsic operator is defined. The sc-structure on T_zO and K_z is that of sc-subspaces of E and F; that it does not depend on the chart is not formalized, and not needed, since the statement holds in every chart. $\mathrm{GrF}(x)$ is not cut down to sc-Fredholm operators (§XV.1); the lemma says what lies in the support.

The hypothesis taken. *Tame germ data for f* (Part I's notion, an sc-Fredholm section whose germs are conjugate to basic germs in tame charts) is not stated in §15.1, where f is "an sc-Fredholm section". It is not new: it is inherited from Part I's Theorems 3.1.18 and 3.6.8, which are proved for tame germ data and on which the proof rests; with the 2021 untamed notion, Theorem 3.6.8 does not hold as we read it `Chapter3/UntamedBundleTheorem · UntamedCorner.theorem_3_6_8_untamed_not` (Part III). The same hypothesis is carried by all of §15.2 (§§XV.12–XV.16) and by the cylinder of Corollary 15.3.10 (§XV.30). Its witness is the graph section of 0 over $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$, which has tame germ data by Part I `Chapter3/NonVacuityG · isScFredholmSectionTame_graphSection`, with the zero multisection; there all hypotheses of the §15.2 theorems hold together `Chapter15/InteriorPerturbationWitness · SBLocalization.theorem_15_2_2_hyp_witness`. The witness has zero fibres, so it shows that the hypotheses are consistent, not that the summands are non-trivially sc-Fredholm; the sc-Fredholm statement itself is a theorem for every f with tame germ data.

XV.12 Definition 15.2.1 (2017: Definition 15.2): transversality

§15.2 (pp. 688–691) is the local theory: what $T(f,\Lambda)$ says about $\mathrm{supp}(\Lambda \circ f)$ near one point. Its tool throughout is the passage of §XV.10 from a branch s_i of a local sc⁺-section structure, a section defined only on an open O, to the sc-Fredholm section $(f-s_i)|_O$ of the restricted strong bundle $W|_O$, to which Part I's implicit function theorems apply. The definitions come first.

Statement (restated). Let f be an sc-Fredholm section functor and Λ an sc⁺-multisection. At a level-1 point x, $T(f,\Lambda)(x)$ *is onto* if every operator in the support of the formal sum $T(f,\Lambda)(x) \in \mathrm{GrF}(x)$ (Definition 15.1.7, §XV.8) is surjective onto W_x `Chapter15/Transversality · SBLocalization.IsOntoAtLevel`. For an arbitrary object x the same is said with the clause $x \in X_1$ built in, since $T(f,\Lambda)$ is defined only on X_1 `Chapter15/Transversality · SBLocalization.IsOntoAt`. (f,Λ) is *transversal at x* if $\Lambda(f(x)) > 0$ and $T(f,\Lambda)(x)$ is onto `Chapter15/Transversality · SBLocalization.IsTransversalAt` (the text's (2)), and *transversal* if it is transversal at every point of $\mathrm{supp}(\Lambda \circ f)$ `Chapter15/Transversality · SBLocalization.IsTransversal` (the text's (1)).

The text phrases the condition twice: as "a nonzero combination of surjective sc-Fredholm operators", and, after "i.e.", as the surjectivity of all $(f-s_i)'(x)$ with $f(x) = s_i(x)$ for a local sc⁺-section structure (s_i). The formal definition is the first phrasing minus the two words that turn out to be automatic; the two lemmas below recover the second phrasing and the word "nonzero", and §XV.11 the word "sc-Fredholm".

The operators of the formal sum. Fix local data at x (§XV.8): a local sc⁺-section structure $(s_i,\sigma_i)_{i\in I}$ of Λ on an open O, with positive weights, and a strong bundle chart c around x with domain in O. Then an operator $L : T_xX \to W_x$ lies in the support of $\sum_{i:f(x)=s_i(x)} \sigma_i \cdot (f-s_i)'(x)$ iff $L = (f-s_i)'(x)$ for some i with $s_i(x) = f(x)$ `Chapter15/Transversality · SBLocalization.mem_support_linSumIntr_iff`. *Proof.* The

formal sum through c is, by definition, the push-forward of the chart-level sum, whose filter is "the principal parts of s_i and f agree at $\varphi(x)$" (§XV.7). For sections over the chart domain this is the same as $s_i(x) = f(x)$, the chart being injective on fibres; this rewrites the filter. The coefficient of L is then $\sum_i [s_i(x) = f(x) \wedge (f - s_i)'(x) = L]\,\sigma_i$, a finite sum of non-negative rationals; it is nonzero iff some term is nonzero, and a term is nonzero iff its condition holds, because $\sigma_i > 0$. So positivity of the weights is exactly what makes "occurs in the sum" the same as "is the derivative of some branch through $f(x)$".

The text's reading `Chapter15/Transversality · SBLocalization.isOntoAtLevel_iff`: for f an sc-Fredholm section functor and any local data at $x \in X_1$, $T(f,\Lambda)(x)$ is onto iff every $(f - s_i)'(x)$ with $s_i(x) = f(x)$, computed through the chart of the data, is surjective. *Proof.* By Definition 15.1.7, $T(f,\Lambda)(x)$ is the formal sum of these data, whichever data are taken `Chapter15/LinearizationIntrinsic · SBLocalization.linearization_eq` (this is Theorem 15.1.1, §XV.7); the support is described by the previous lemma; the two directions are then immediate. The text's "if (s_i) is a local sc⁺-section structure" is thereby read "for any", which Theorem 15.1.1 makes the same as "for some".

"Nonzero" is automatic `Chapter15/Transversality · SBLocalization.linearization_ne_zero`: at $x \in X_1$ with $\Lambda(f(x)) > 0$, $T(f,\Lambda)(x) \neq 0$. *Proof.* Local data exist at every level-1 point `Chapter15/LinearizationIntrinsic · SBLocalization.nonempty_localLinData`. The count formula of the local structure, evaluated at the point $f(x)$ of the fibre over x, gives $\Lambda(f(x)) = \sum_{i : s_i(x) = f(x)} \sigma_i$; if no branch passed through $f(x)$ the sum would be empty and $\Lambda(f(x)) = 0$. So some i has $s_i(x) = f(x)$, the operator $(f - s_i)'(x)$ lies in the support of the formal sum, and a formal sum with nonempty support is not 0.

"sc-Fredholm" is automatic as well, for f with Part I's tame germ data: every operator of the support is, read in the chart, sc-Fredholm (§XV.11). So Definition 15.2.1 asks only for surjectivity, and that is what the formal definition says.

Where the support lives. $T(f,\Lambda)$ is defined on X_1, so the formal definition carries "$x \in X_1$". Under the tame germ data this costs nothing: every point of the support is smooth. *One branch* `Chapter15/Transversality · SBLocalization.mem_smoothSet_of_eq`: if s is sc⁺ on an open $O \ni y$ and $f(y) = s(y)$, then y is a zero of the section $(f - s)|_O$ of $W|_O$ `Chapter15/LocalScPlus · SBLocalization.isZeroAt_subSec_iff`, which is a tame sc-Fredholm section (§XV.10) `Chapter15/LocalScPlus · SBLocalization.isScFredholmSectionTame_subRestrict`; zeros of sc-Fredholm sections are smooth points (Part I) `Chapter3/TameGermsG · StrongBundle.IsScFredholmSection.mem_smoothSet_of_isZeroAt`, and a point of the open M-polyfold O is smooth there iff it is smooth in X. *The support* `Chapter15/Transversality · SBLocalization.mem_smoothSet_of_pos`: if $\Lambda(f(y)) > 0$, the count formula of a local structure around y produces a branch with $f(y) = s_i(y)$, as in the previous proof, and the one-branch lemma applies. The same fact without tame germ data, $\operatorname{supp}(\Lambda \circ f) \subset X_1$, is proved for Definition 15.3.5 in §XV.20 `Chapter15/ControllingPairs · SBLocalization.mem_levelSet_one_of_pos`.

A witness. Over the trivial ep-groupoid of $\mathbb{R}^n$, the strong bundle $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$ with the graph section of 0 and the trivial multisection Λ_0 (Chapter 13; $\Lambda_0(w) = 1$ on the zero vectors, 0 elsewhere) is transversal, with $\Lambda_0(f(x)) = 1$ at every point `Chapter15/InteriorPerturbationWitness · SBLocalization.theorem_15_2_2_hyp_witness`. The fibres are $\{0\}$, so every operator into a fibre is onto. The example has zero fibres: it shows that the definition is satisfiable with nonempty support, not more.

XV.13 Theorem 15.2.2 (2017: Theorem 15.2): interior local perturbation

Statement (narrower) `Chapter15/Transversality · SBLocalization.theorem_15_2_2_hyp`. Let f be an sc-Fredholm section functor *with Part I's tame germ data*, Λ an sc⁺-multisection, $d_X(x) = 0$, and (f,Λ) transversal

at x. Then there are a natural representation $U(x)$ of G_x (Theorem 7.1.13), a local sc$^+$-section structure $(s_i, \sigma_i)_{i\in I}$ of Λ on an open O, and a strong bundle chart c with $U(x) \subset \mathrm{dom}(c) \subset O$, such that, with $M_i = \{y \in U(x) : f(y) = s_i(y)\}$:

1. $d_X(y) = 0$ for all $y \in U(x)$;
2. $T(f, \Lambda)(y)$ is onto at every $y \in U(x)$ with $\Lambda(f(y)) > 0$;
3. (a) every M_i is a smooth finite-dimensional submanifold of X (Definition 4.2.1); (b) the inclusion $M_i \hookrightarrow U(x)$ is a proper map; (c) $\{y \in U(x) : \Lambda(f(y)) > 0\} = \bigcup_i M_i$; (d) $\Lambda(f(y)) = \sum_{i:f(y)=s_i(y)} \sigma_i$ on $U(x)$; (e) $T(f, \Lambda)(y) = \sum_{i:f(y)=s_i(y)} \sigma_i \cdot (f - s_i)'(y)$, the operators read in c, at every level-1 point y of $\mathrm{dom}(c)$;

and, in addition, a branch meets f in $U(x)$ only if it passes through $f(x)$: $f(y) = s_i(y)$ for some $y \in U(x)$ implies $s_i(x) = f(x)$.

Narrower only by the tame germ data. The text's hypothesis $x \in \mathrm{supp}(\Lambda \circ f)$ is part of transversality at x.

Proof. The text's proof is four sentences: choose $U'(x)$ and a local structure on it; by assumption $f(x) = s_i(x)$ for all i; apply the implicit function theorem to each $f - s_i$; intersect. The Lean proof follows it, with two additions: the branches that do not pass through $f(x)$ are handled separately, and every step is read through one chart inside the domain of the structure, so that §§XV.8 and XV.10 apply.

Step 1, a structure and a chart inside it. Since Λ is an sc$^+$-multisection, there is a natural representation $U_0(x)$ with a local sc$^+$-section structure $(s_i, \sigma_i)_{i\in I}$ on $U_0(x)$ (Definition 13.2.5 in its 2021 reading, Part XIII). Choose any strong bundle chart c_0 around x in the atlas and restrict it to $\mathrm{dom}(c_0) \cap U_0(x)$, which is open; the restriction is a chart of the atlas, and its domain lies in the domain of the structure. Call it c. The structure and c are local data at x in the sense of Definition 15.1.7 `Chapter15/LinearizationIntrinsic · SBLocalization.LocalLinData`.

Step 2, from transversality to the chart. Transversality at x gives $x \in X_1$ and $T(f, \Lambda)(x)$ onto; by the text's reading (§XV.12) `Chapter15/Transversality · SBLocalization.isOntoAtLevel_iff`, every intrinsic $(f - s_i)'(x)$ with $s_i(x) = f(x)$ is surjective. The intrinsic operator is onto W_x iff the chart operator $D((\widehat{f} - \widehat{s}_i) \circ r)(z)$ maps $T_z O$ onto the fibre K_z at the level-1 chart point z over $\varphi(x)$ `Chapter15/LocalIFT · SBLocalization.surjective_toIntr_subDeriv_iff` (§XV.10).

Step 3, one branch `Chapter15/Transversality · SBLocalization.exists_branch_interior`. For each i there is an open $V_i \ni x$ inside $\mathrm{dom}(c)$ such that $\{y \in V_i : f(y) = s_i(y)\}$ is a smooth submanifold, every point y of it is smooth and has the chart operator of $f - s_i$ onto at every chart point over $\varphi(y)$, and, if some $y \in V_i$ has $f(y) = s_i(y)$, then $s_i(x) = f(x)$. Two cases.

- *The branch passes through $f(x)$.* Then the chart operator is onto at x (Step 2), and the interior local solution lemma of §XV.10 `Chapter15/LocalIFT · SBLocalization.exists_solutionSet_interior` gives V_i: it is Part I's implicit function theorem (Theorem 3.6.8) for the tame sc-Fredholm section $(f - s_i)|_O$ of $W|_O$ at its zero x, where $d_X(x) = 0$ makes the good position automatic, read back in X through the inclusion $O \to X$. The last clause holds trivially.
- *The branch does not pass through $f(x)$.* Then $V_i = \{y \in \mathrm{dom}(c) : f(y) \neq s_i(y)\}$. It is open `Chapter15/Transversality · SBLocalization.isOpen_sep_ne`: f is continuous, s_i is continuous on O `Chapter15/Transversality · SBLocalization.IsScPlusSectionOn.continuousOn` (an sc$^+$-section is the composite of a continuous lift to $W_{0,1}$ with the continuous inclusion $W_{0,1} \to W$), and the set where two continuous maps into a Hausdorff space differ is the preimage of the complement of the closed diagonal. It

contains x. The solution set in V_i is empty, so it is a submanifold, and the remaining clauses hold vacuously.

The second case is where the formal statement departs from the text's proof, which says "by assumption, $f(x) = s_i(x)$ for $i \in I$". That holds only for the branches through $f(x)$; presumably the text means those, the others having empty solution sets near x. The formal statement keeps the whole index set, and the last clause of the theorem says that the other branches contribute nothing on $U(x)$.

Step 4, the neighbourhood. The set $\mathrm{dom}(c) \cap \bigcap_i V_i \cap \{d_X = 0\}$ is open, the last set being open because the degeneracy index is upper semicontinuous, and it contains x. A natural representation can be shrunk into any open neighbourhood of x `Chapter7/NaturalRep · EpGroupoid.exists_naturalRep_shrink` (Theorem 7.1.13); this gives $U(x) \subset U_0(x)$. Property (1) holds by construction.

Step 5, the count. For $y \in U(x)$ the count formula of the structure at the point $f(y)$ gives (d), $\Lambda(f(y)) = \sum_{i:f(y)=s_i(y)} \sigma_i$. Since the weights are positive, $\Lambda(f(y)) > 0$ iff some branch passes through $f(y)$; this gives (c).

Step 6, (2). Let $y \in U(x)$ with $\Lambda(f(y)) > 0$. By Step 5 some i has $f(y) = s_i(y)$; then y lies in the solution set of Step 3 for that branch, hence is smooth and in particular at level 1. The same structure with the chart c is local data at y, so by the text's reading it suffices that each $(f - s_j)'(y)$ with $s_j(y) = f(y)$ is onto; Step 3 for the branch j gives the chart operator onto at y, and §XV.10 turns this into the intrinsic surjectivity `Chapter15/LocalIFT · SBLocalization.surjective_toIntr_subDeriv_iff`.

Step 7, (a) and (b). $M_i = \{y \in V_i : f(y) = s_i(y)\} \cap U(x)$, the intersection of a smooth submanifold with an open set, which is again one. For (b), an inclusion of a subset is a proper map iff the subset is closed; M_i is the set of points of $U(x)$ where the two continuous maps f and s_i agree, which is closed in $U(x)$.

Step 8, (e). At a level-1 point y of $\mathrm{dom}(c)$, the structure and c are local data at y, and Definition 15.1.7 gives $T(f, \Lambda)(y)$ as their formal sum `Chapter15/LinearizationIntrinsic · SBLocalization.linearization_eq`. The last clause is the last clause of Step 3.

Readings. (i) "$d_{M_i} \equiv 0$ and therefore a natural (classical) smooth manifold structure" in (a) is read as Definition 4.2.1 inside $\{d_X = 0\}$, which (1) provides; Definition 4.2.1 allows boundary and corners and here has none. (ii) The text's (e) "for $y \in U(x)$" uses the structure on $U(x)$; the formal (e) is read in the chart c, which is no restriction, since the formal sum does not depend on the chart (§XV.7). (iii) The text's "$f_i(y) = s_i(y)$" in (e) is read $f(y) = s_i(y)$. (iv) The index set is that of the structure; $M_i = \emptyset$ for the branches not through $f(x)$.

The added hypothesis. *Tame germ data for f* (Part I's sc-Fredholm sections with germ data in tame charts), not stated in §15.2, which says only "f an sc-Fredholm section functor". It is inherited, not new: the proof is Part I's Theorem 3.6.8 applied to $(f - s_i)|_O$, and Part I proves that theorem for tame germ data; with the untamed 2021 notion of an sc-Fredholm germ Theorem 3.6.8 does not hold as we read it `Chapter3/UntamedBundleTheorem · UntamedCorner.theorem_3_6_8_untamed_not` (Part III). The restriction to O keeps tame germ data, and the sc$^+$-perturbation by $-s_i$ keeps them by Part I's Theorem 3.1.18 (§XV.10). No ep-level counterexample to the untamed §15.2 was built. *Witness* of all hypotheses together `Chapter15/InteriorPerturbationWitness · SBLocalization.theorem_15_2_2_hyp_witness`: the example of §XV.12, where the graph section of 0 has tame germ data by Part I `Chapter3/NonVacuityG · isScFredholmSectionTame_graphSection`, Λ_0 is an sc$^+$-multisection, $d_X \equiv 0$ on $\mathbb{R}^n$, $\Lambda_0(f(x)) = 1$ and (f, Λ_0) is transversal everywhere. The example has zero fibres: it witnesses consistency, and the solution sets are all of $\mathbb{R}^n$.

XV.14 Remark 15.2.3 (2017: Remark 15.2): $\Lambda \circ f$ is locally branched; tame; the ep-groupoid $U(x)$

The remark says that on the ep-groupoid $U(x)$ the functor $z \mapsto \Lambda(f(z))$ is a branched, tame ep⁺-subgroupoid with support $M_{U(x)}$. The formalization proves it in three forms: as a local branching structure at a point of X, as a global statement on X, and on the ep-groupoid $U(x)$ itself, each also with "tame".

Local form (narrower) `Chapter15/Transversality · SBLocalization.remark_15_2_3_hyp`. With tame germ data for f: at a point y with $d_X(y) = 0$ where (f, Λ) is transversal, $z \mapsto \Lambda(f(z))$ has a local branching structure at y in the sense of Definition 9.1.2 (2)–(4) (Part IX): an open $U \ni y$, finitely many smooth submanifolds $M_j \subset U$ through y with proper inclusions, and positive rational weights σ_j with $\Lambda(f(z)) = \sum_{j : z \in M_j} \sigma_j$ on U. *Proof.* Theorem 15.2.2 at y gives $U(y)$, the structure $(s_i, \sigma_i)_{i \in I}$, the sets M_i and (a)–(d). The index set of the branching structure is the set of branches through $f(y)$, $\{i \in I : s_i(y) = f(y)\}$, so that every M_j contains y, as Definition 9.1.2 asks; the submanifold property and properness are (a) and (b); the weights are positive. The count is computed in three rewrites: by (d), $\Lambda(f(z)) = \sum_{i \in I} [f(z) = s_i(z)]\, \sigma_i$; by the last clause of Theorem 15.2.2 every branch with $f(z) = s_i(z)$ for some $z \in U(y)$ passes through $f(y)$, so the sum may be restricted to the branches through $f(y)$; and that sum is the sum over the index set of the structure, after reindexing by the subtype.

Global form (narrower) `Chapter15/Transversality · SBLocalization.remark_15_2_3_isBranchedEpSubgroupoid_hyp`. With tame germ data: if (f, Λ) is transversal, $d_X = 0$ on $\operatorname{supp}(\Lambda \circ f)$, and the orbit space $|\operatorname{supp}(\Lambda \circ f)|$ is paracompact, then $\Lambda \circ f$ is a branched ep⁺-subgroupoid of X (Definition 9.1.2). *Proof*, field by field. The values are non-negative rationals. Functoriality: for a morphism φ, $f(t(\varphi)) = \mu(\varphi, f(s(\varphi)))$ because f is a section functor, and $\Lambda(\mu(\varphi, w)) = \Lambda(w)$ because Λ is a functor on W; so $\Lambda(f(t(\varphi))) = \Lambda(f(s(\varphi)))$. The support consists of smooth points (§XV.12) `Chapter15/Transversality · SBLocalization.mem_smoothSet_of_pos`. The paracompactness of the orbit space of the support, Definition 9.1.2 (1), is the hypothesis. The local branching structures at the support points are the local form. *Narrower* also by that hypothesis: Definition 9.1.2 (1) is new in the 2021 edition, and the remark, being local, does not address it. *Witness* `Chapter15/InteriorPerturbationWitness · SBLocalization.remark_15_2_3_isBranchedEpSubgroupoid_hyp_witness`: the example of §XV.12, with the paracompactness of the orbit space of any subset of the trivial ep-groupoid of $\mathbb{R}^n$ from Part IX `Chapter9/Propositions · EpGroupoid.paracompactSpace_orbitSupp_trivial_rn`.

"Tame". A tame local branching structure (Definition 9.3.6) is a local branching structure whose domain is a natural representation with the properness property (Definition 7.5.8) and whose submanifolds M_j have tame induced structures (Definition 2.5.18). At an interior point of transversality (f, Λ) is in good position (Definition 15.2.4; the lemma is in §XV.15), and at a point of good position Theorem 15.2.5 produces a tame local branching structure (§XV.16). Hence *the local tame form* (narrower) `Chapter15/TameBranched · SBLocalization.remark_15_2_3_tame_hyp`: at y with $d_X(y) = 0$ and (f, Λ) transversal at y, $z \mapsto \Lambda(f(z))$ has a tame local branching structure at y; and *the global tame form* (narrower) `Chapter15/TameBranched · SBLocalization.remark_15_2_3_isTameBranched_hyp`: under the hypotheses of the global form, $\Lambda \circ f$ is a branched ep⁺-subgroupoid and tame, by the global form of Theorem 15.2.5 (§XV.16) applied with good position at every support point. *Witness* `Chapter15/TameWitness · SBLocalization.remark_15_2_3_isTameBranched_hyp_witness`: the example of §XV.12, with support all of $\mathbb{R}^n$.

The ep-groupoid $U(x)$. *Reading.* "The ep-groupoid $U(x)$" is read as the translation groupoid $G_x \ltimes U(x)$ of the natural action of the isotropy group on a natural representation, whose objects are the points of $U(x)$ and whose morphisms are the pairs (g, y) from y to $g{*}y$ `Chapter7/NaturalAction · EpGroupoid.NaturalRep.`

translationEpGroupoid. Part VII proves that it is an ep-groupoid and that the functor $\Gamma : G_x \ltimes U(x) \to X$ is fully faithful onto the full subcategory of X on $U(x)$ (Theorem 7.1.13 (3)), with the same orbit space (Proposition 7.1.19). So the full subcategory on $U(x)$ is an ep-groupoid in this form. The restriction of a functor Θ on X to it is $\Theta_U(y) = \Theta(y)$, and "with support $M_{U(x)}$" is then the definition of the support of Θ_U.

The generic step (extra) Chapter15/RestrictedEp · EpGroupoid.NaturalRep.isTameBranched_translation. For any ep-groupoid X, natural representation $U(x)$ and functor $\Theta \geq 0$ on X with closed support, such that every point of $\operatorname{supp}\Theta \cap U(x)$ is smooth and carries a tame local branching structure of Θ, the restriction Θ_U is a branched ep⁺-subgroupoid of $G_x \ltimes U(x)$, and tame. Unlike the global form on X, no paracompactness is assumed: on $G_x \ltimes U(x)$ it is proved. *Proof*, field by field.

- *Functoriality.* A morphism (g, y) of the translation groupoid is carried by Γ to a morphism of X with source y and target $g * y$, so $\Theta(g * y) = \Theta(y)$ by functoriality of Θ on X.
- *Smoothness.* A point of the open sub-M-polyfold $U(x)$ is smooth there iff it is smooth in X.
- *Paracompactness of the orbit space of the support* Chapter15/RestrictedEp · EpGroupoid.NaturalRep.paracompactSpace_orbitSupp_translation. Let $S = \operatorname{supp}\Theta_U$, closed in $U(x)$, hence paracompact, and let $p : S \to |S|$ be the orbit map restricted to it, continuous and onto. Two facts about the orbit map π of $G_x \ltimes U(x)$. It is closed Chapter15/RestrictedEp · EpGroupoid.NaturalRep.isClosedMap_translation_π: every closed subset C of $U(x)$ is a proper subset of the translation groupoid in the sense of Definition 7.5.8 Chapter15/RestrictedEp · EpGroupoid.NaturalRep.translation_isProperSubset, because Part VII proves that the restriction of the source–target map to the morphisms over the closure of any subset is proper Chapter7/NaturalAction · EpGroupoid.NaturalRep.translation_isProperMap, and the orbit of a proper subset is closed (Proposition 7.5.10 (1)) Chapter7/ProperSubsets · EpGroupoid.proposition_7_5_10_one. Its fibres are finite Chapter15/RestrictedEp · EpGroupoid.NaturalRep.finite_fiber_translation_π: two points of $U(x)$ have the same orbit iff they differ by the action of an element of G_x, so a fibre is the image of the finite group G_x under $g \mapsto g * y$. Restricted to the closed set S, p is again closed with finite fibres. Now Michael's criterion (Lemma 2.7.3) Chapter7/Michael · paracompactSpace_of_closed_refinement: a regular space is paracompact if every open cover has a locally finite closed refinement that covers. Given an open cover of $|S|$, pull it back to S, take a locally finite closed precise refinement there Chapter7/Michael · exists_closed_precise_refinement, and push it forward by p. The images are closed (p closed), cover (p onto), refine the cover, and form a locally finite family by the next lemma.
- *Closed maps with finite fibres* Chapter15/RestrictedEp · locallyFinite_image_of_isClosedMap: a closed map p with finite fibres carries a locally finite family (v_i) to a locally finite family $(p(v_i))$. *Proof.* Fix y. Each point z of the finite fibre $p^{-1}(y)$ has a neighbourhood N_z meeting only finitely many v_i. The union W of the interiors of the N_z is open and contains the fibre, so $y \notin p(W^c)$, and $(p(W^c))^c$ is an open neighbourhood of y, p being closed. If $p(v_i)$ meets it, at a point $p(z)$ with $z \in v_i$, then $z \notin W^c$, so z lies in some $N_{z'}$ and v_i meets $N_{z'}$; there are finitely many such i for each of the finitely many z'.
- *Tame local branching structures move into $U(x)$* Chapter15/RestrictedEp · EpGroupoid.NaturalRep.nonempty_tameBranching_translation. Let C be a tame local branching structure of Θ at $y \in U(x)$, with domain $C.U$. Theorem 7.1.13 for the translation groupoid Chapter7/NaturalRep · EpGroupoid.theorem_7_1_13 gives a natural representation U' of $G_x \ltimes U(x)$ at y inside the preimage of $C.U$; its image in X is open and inside $C.U \cap U(x)$. The structure C is restricted to this image (the M_j intersected with an open set stay submanifolds with tame induced structures), and moved into the M-polyfold $U(x)$ by the inclusion $U(x) \to X$, an sc-diffeomorphism onto its open image Chapter8/TangentLocal · MPolyfold.

`isScDiffeoOn_subtypeVal`; images of tame induced structures under sc-diffeomorphisms are tame. The properness property of U' inside the translation groupoid holds for every open subset of $U(x)$ `Chapter15/RestrictedEp · EpGroupoid.NaturalRep.translation_hasPropernessProperty`, since every closed subset is proper there.

Remark 15.2.3 on the ep-groupoid $U(x)$ (narrower) `Chapter15/RestrictedEp · SBLocalization.remark_15_2_3_restricted_hyp`. With tame germ data: at x with $d_X(x) = 0$ and (f, Λ) transversal at x, there is a natural representation $U(x)$ with $d_X \equiv 0$ on it such that $z \mapsto \Lambda(f(z))$ is a branched ep$^+$-subgroupoid of $G_x \ltimes U(x)$, and tame. *Proof.* Theorem 15.2.2 at x gives $U(x)$ with (1) and (2). Apply the generic step to $\Theta = \Lambda \circ f$: it is ≥ 0 and a functor `Chapter15/GeneralPositionBranched · SBLocalization.isFunctorial_comp`; its support is closed in X `Chapter15/GeneralPositionBranched · SBLocalization.isClosed_supp_comp`, being locally the finite union of the closed sets $\{f = s_i\}$ (§XV.21); its support points are smooth (§XV.12); and at a support point $y \in U(x)$, $d_X(y) = 0$ by (1) and (f, Λ) is transversal at y by (2), so the local tame form above gives a tame local branching structure at y. *No paracompactness* is assumed: the remark holds on $U(x)$ exactly as stated, with the inherited tame germ data. *Witness* `Chapter15/TameWitness · SBLocalization.remark_15_2_3_restricted_hyp_witness`: all hypotheses together at $0 \in \mathbb{R}^1$ in the example of §XV.12, with the conclusion.

XV.15 Definition 15.2.4 (2017: Definition 15.3): good position

At a point with $d_X(x) \geq 1$ transversality is not enough: the kernels must also sit well against the boundary. The text calls Definition 15.2.4 "a version of Definition 3.6.6"; the formalization makes it exactly that, branch by branch.

Statement (restated). *One branch* `Chapter15/BoundaryPerturbation · SBLocalization.IsBranchGoodPosition`: for s sc$^+$ on an open $O \ni x$, the branch $f - s$ is in good position at x if the section $(f - s)|_O$ of $W|_O$ is in good position at x in a tame chart, Part I's Definition 3.6.6 in its tame germ reading: germ data at x in a tame chart of $W|_O$, a linearization at x that is onto, and a kernel in good position to the partial quadrant (Definition 3.1.24). *The pair* `Chapter15/BoundaryPerturbation · SBLocalization.IsGoodPositionAt`: (f, Λ) is in good position at x if $\Lambda(f(x)) > 0$, $T(f, \Lambda)(x)$ is onto (Definition 15.2.1), and there is a local sc$^+$-section structure (s_i, σ_i) of Λ on an open $O \ni x$ such that every branch with $s_i(x) = f(x)$ is in good position at x.

Readings. (i) The text's (1), "X is tame near x", and (3), "the kernels of the L_i are in good position to $C_x X$", are read together per branch as Part I's good position of $(f - s_i)|_O$, which carries a tame chart at x (giving (1)) and the kernel condition (giving (3)). (ii) The condition is asked for one local structure; the text does not say whether it depends on the structure chosen. Theorem 15.2.5 below propagates it with the same structure. (iii) The text assumes $x \in \partial X$; the formal definition does not, and everything below holds at any point where the condition holds.

At an interior point, transversality is good position (extra) `Chapter15/TameBranched · SBLocalization.isGoodPositionAt_of_interior`: if $d_X(x) = 0$ and (f, Λ) is transversal at x (f with tame germ data), then (f, Λ) is in good position at x. *Proof.* Take the structure (s_i, σ_i) on a natural representation $U_0(x)$ and a chart c inside it, as in Step 1 of §XV.13. For a branch through $f(x)$, transversality and the text's reading give the chart operator onto at x (Step 2 of §XV.13); this is Part I's surjectivity of the linearization of $(f - s_i)|_{U_0(x)}$ at x `Chapter15/LocalIFT · SBLocalization.isLinSurjAt_subRestrict` (§XV.10). The degeneracy index of x in the open M-polyfold $U_0(x)$ is that in X, so 0. Part I: at a zero with $d = 0$, an onto linearization is good position in a tame chart `Chapter3/GlobalIFTIndexG · StrongBundle.isGoodPositionGerm_of_isLinSurjAt`, since at an interior point the partial quadrant is the whole space and the kernel condition is empty. So

every branch through $f(x)$ is in good position, which is Definition 15.2.4.

This lemma is what lets the tame forms of Remark 15.2.3 (§XV.14) be derived from those of Theorem 15.2.5 (§XV.16).

Witness `Chapter15/GoodPositionWitness · SBLocalization.theorem_15_2_5_hyp_witness`: in the example of §XV.12, (f, Λ_0) is in good position at every point of $\mathbb{R}^n$. *Proof.* There every pair is in general position (Definition 15.3.5), the fibres being 0 `Chapter15/GeneralPositionBranched · SBLocalization.isInGeneralPosition_epSEP_zero`, and general position gives good position at every point of the support (Remark 15.3.6, §XV.20) `Chapter15/GoodPositionBranches · SBLocalization.remark_15_3_6_goodPosition_hyp`. Zero fibres: a consistency witness.

XV.16 Theorem 15.2.5 (2017: Theorem 15.3) and Remark 15.2.6: boundary local perturbation, tame, and under general position

Statement (narrower) `Chapter15/BoundaryPerturbation · SBLocalization.theorem_15_2_5_hyp`. Let f be an sc-Fredholm section functor with tame germ data, Λ an sc$^+$-multisection, and (f, Λ) in good position at x. Then there are a natural representation $U(x)$, a local sc$^+$-section structure (s_i, σ_i) on an open O and a chart c with $U(x) \subset \mathrm{dom}(c) \subset O$ such that, with $M_i = \{y \in U(x) : f(y) = s_i(y)\}$: every M_i is a smooth submanifold (Definition 4.2.1); (1) the inclusions $M_i \hookrightarrow U(x)$ are proper; $\{y \in U(x) : \Lambda(f(y)) > 0\} = \bigcup_i M_i$; (2) (f, Λ) is in good position, with the same structure, at every $y \in U(x)$ with $\Lambda(f(y)) > 0$, so $T(f, \Lambda)(y)$ is onto with the branches in good position; (3) $\Lambda(f(y)) = \sum_{i : y \in M_i} \sigma_i$ on $U(x)$; $T(f, \Lambda)(y) = \sum_{i : f(y) = s_i(y)} \sigma_i \cdot (f - s_i)'(y)$ in c; and only the branches through $f(x)$ meet f in $U(x)$. "Tame submanifolds" and "tame branched" are the tame form below. *Narrower* by the inherited tame germ data; $x \in \partial X$ is not required.

Proof. The text: "along the lines of the proof of Theorem 15.2.2", with Part I's implicit function theorem in good position. The Lean proof is that proof with the good-position lemma in place of the interior one.

Step 1. Good position at x supplies the structure (s_i, σ_i) on an open $O \ni x$ in which the branches through $f(x)$ are in good position. Take a chart c_0 around x and restrict it to $\mathrm{dom}(c_0) \cap O$: a chart c with domain in O. A natural representation $U_0(x)$ is taken from the multisection property of Λ; only its existence is used, for the shrinking in Step 3.

Step 2, one branch `Chapter15/BoundaryPerturbation · SBLocalization.exists_branch_goodPosition`: for each i an open $V_i \ni x$ in $\mathrm{dom}(c)$ with $\{y \in V_i : f(y) = s_i(y)\}$ a smooth submanifold, each of its points smooth, with the branch in good position there and the chart operator onto there, and only meeting f if $s_i(x) = f(x)$. If the branch passes through $f(x)$ this is the good-position local solution lemma of §XV.10 `Chapter15/LocalIFT · SBLocalization.exists_solutionSet_of_isGoodPosition`: Part I's Theorem 3.6.8 for $(f - s_i)|_O$ at x in good position, which gives an open set of the zeros of which each is in good position, read back in X; the chart surjectivity at those zeros comes from the good position there. If it does not, $V_i = \{y \in \mathrm{dom}(c) : f(y) \neq s_i(y)\}$, as in §XV.13 `Chapter15/Transversality · SBLocalization.isOpen_sep_ne`.

Step 3. Shrink $U_0(x)$ into the open set $\mathrm{dom}(c) \cap \bigcap_i V_i$ `Chapter7/NaturalRep · EpGroupoid.exists_naturalRep_shrink`. No condition on d_X enters.

Step 4. The count (3), the description of the support, the submanifolds M_i, the properness (1) and the formula for $T(f, \Lambda)$ are proved word for word as Steps 5, 7 and 8 of §XV.13.

Step 5, (2). At $y \in U(x)$ with $\Lambda(f(y)) > 0$: some branch passes through $f(y)$, so y is smooth, hence at

level 1, by Step 2. The structure on O and the chart c are local data at y; every branch j through $f(y)$ has its chart operator onto at y (Step 2), so $T(f,\Lambda)(y)$ is onto by the text's reading of §XV.12 `Chapter15/LocalIFT · SBLocalization.surjective_toIntr_subDeriv_iff`; and every branch j through $f(y)$ is in good position at y (Step 2). These are the three clauses of Definition 15.2.4 at y, with the same structure.

Tame local solution sets (extra) `Chapter15/TameBranched · SBLocalization.exists_tame_solutionSet_of_isBranchGoodPosition`. If a branch $f - s$ with $f(x) = s(x)$ is in good position at x, there is an open $V \ni x$ inside O such that $\{y \in V : f(y) = s(y)\}$ is a smooth submanifold of X with a tame induced structure (Definition 2.5.18). *Proof.* Part I's Theorem 3.1.26, the implicit function theorem in the boundary case, for the tame sc-Fredholm section $(f-s)|_O$ at its zero x in good position `Chapter3/GlobalIFTNearbyOntoG · theorem_3_1_26'`, gives an open $U \subset O$ around x whose zeros are smooth and in good position and whose zero set is a sub-M-polyfold with a tame induced structure. The zero set in U is a smooth submanifold of O `Chapter5/GeneralPosition · StrongBundle.isSmoothSubmanifold_solutionSet_inter`, the zeros of $(f-s)|_O$ being the points with $f = s$ `Chapter15/LocalScPlus · SBLocalization.isZeroAt_subSec_iff`. Both properties are carried to X by the sc-diffeomorphism $O \to X$ onto the open set O `Chapter8/TangentLocal · MPolyfold.isScDiffeoOn_subtypeVal`; V is the image of U.

Theorem 15.2.5, tame (narrower) `Chapter15/TameBranched · SBLocalization.theorem_15_2_5_tame_hyp`. In good position at x, $z \mapsto \Lambda(f(z))$ has a tame local branching structure at x (Definition 9.3.6): a natural representation $U(x)$ with the properness property, the sets $M_j = \{z \in U(x) : f(z) = s_j(z)\}$ over the branches through $f(x)$, each a smooth submanifold with a tame induced structure and a proper inclusion, the weights σ_j, and the count. *Proof.* For every branch choose V_i: the tame local solution set above if the branch passes through $f(x)$, and $\{y \in O : f(y) \neq s_i(y)\}$ otherwise. Every object has a neighbourhood Q with the properness property (Definition 7.5.8) `Chapter7/EpGroupoid · EpGroupoid.exists_hasPropernessProperty`. Theorem 7.1.13 `Chapter7/NaturalRep · EpGroupoid.theorem_7_1_13` gives a natural representation $U(x)$ inside the open set $Q \cap O \cap \bigcap_i V_i$; it has the properness property, its closure lying in that of Q. The M_j are the intersections of the tame solution sets with the open $U(x)$, which keeps both the submanifold property and the tame induced structure; properness and the count are as in the local form of Remark 15.2.3 (§XV.14), with the index set the branches through $f(x)$. This is the text's "by definition $\Lambda \circ f$ … is a tame branched ep⁺-subgroupoid, since it is represented by tame submanifolds".

The global tame form (narrower) `Chapter15/TameBranched · SBLocalization.theorem_15_2_5_isTameBranched_hyp`: if (f,Λ) is in good position at every point of the support and $|\operatorname{supp}(\Lambda \circ f)|$ is paracompact, then $\Lambda \circ f$ is a branched ep⁺-subgroupoid of X and tame; the fields are those of the global form of Remark 15.2.3 (§XV.14), with functoriality `Chapter15/GeneralPositionBranched · SBLocalization.isFunctorial_comp` and the tame local branching structures just proved. The same assembly gives the global tame form of Remark 15.2.3 (§XV.14), and, through good position from general position (Remark 15.3.6), the tame forms of Remark 15.3.6 `Chapter15/TameBranched · SBLocalization.remark_15_3_6_isTameBranched_hyp` and of the "in particular" of Theorem 15.3.7 `Chapter15/TameBranched · SBLocalization.theorem_15_3_7_in_particular_tame_hyp` (§§XV.20–XV.21).

On the ep-groupoid $U(x)$ (narrower) `Chapter15/RestrictedEp · SBLocalization.theorem_15_2_5_restricted_hyp`: in good position at x, there is a natural representation $U(x)$ on whose translation groupoid $G_x \ltimes U(x)$ the functor $z \mapsto \Lambda(f(z))$ is a branched ep⁺-subgroupoid, and tame. *Proof.* Theorem 15.2.5 gives $U(x)$ with good position at every support point in it; the generic step of §XV.14 applies, the tame local branching structures at those points coming from the tame form above. No paracompactness is assumed.

The closing sentence: general position. The text: the same conclusion holds if (2) is replaced by the requirement that the restrictions of $T(f,\Lambda)(y)$ to the reduced tangent spaces $T^R_y X$ are surjective, pointing

ahead to Definition 15.3.5.

Definition 15.3.5 at one point Chapter15/GeneralPositionLocal · SBLocalization.IsReducedOntoAtLevel Chapter15/GeneralPositionLocal · SBLocalization.IsInGeneralPositionAt: (f, Λ) is in general position at x if $x \in X_1$ and every operator L of $T(f, \Lambda)(x)$, restricted to $T^R_x X$, is onto W_x, with $T^R_x X$ read in every chart around x and every presentation of its partial quadrant (Part I's reduced tangent fibre). Definition 15.3.5 (§XV.20) is this condition at every point of the support Chapter15/GeneralPositionLocal · SBLocalization.isInGeneralPosition_iff_forall_at, the support lying in X_1 Chapter15/ControllingPairs · SBLocalization.mem_levelSet_one_of_pos.

Reading. "(2) replaced by general position" is read: the hypothesis "good position at x" is replaced by "general position at x", and the conclusion (2) by "general position at every point of $M_{U(x)}$". Good position at x and on $M_{U(x)}$ still holds, so the formal conclusion gives both forms of (2).

Four lemmas connect general position of the pair to Part I's general position of the branches (Definition 5.3.9 for $(f - s_i)|_O$: the linearization at the zero is onto, with kernel transversal to T^R).

- *Part I, in every chart* (extra) Chapter15/GeneralPositionLocal · StrongBundle.linKer_sup_reduced_eq_of_isGeneralPositionAt: if a smooth submanifold A of the solution set of a section f is in general position at y (Definition 4.2.10), then in every strong bundle chart around y, at every level-1 point z over $\varphi(y)$ and for every presentation of the partial quadrant, $\ker \mathrm{Lin}(z) + T^R_z O = T_z O$. *Proof.* General position of A gives, in the chart, a splitting $T_z O = N \oplus B$ with N the tangent space of A and $B \subset T^R_z O$. The tangent space of a submanifold of zeros lies in the kernel of the linearization, so $N \subset \ker \mathrm{Lin}(z)$; hence $T_z O = N + B \subset \ker \mathrm{Lin}(z) + T^R_z O \subset T_z O$. This is the converse of Part I's chart criterion Chapter5/CylinderPerturbation2021 · isGeneralPositionGerm_of_sup_eq, and it holds in every chart, not only in the chart of the germ data.
- *From the pair to the branches* Chapter15/GeneralPositionLocal · SBLocalization.isGeneralPositionGerm_branch_at: if (f, Λ) is in general position at x, every branch $(f - s_i)|_O$ through $f(x)$ of any local structure on an open $O \ni x$ is in Part I's general position at x. *Proof.* The point x is smooth (§XV.12) Chapter15/Transversality · SBLocalization.mem_smoothSet_of_eq, so the tame germ data of f provide a tame chart centred at x; restrict it to O. With the structure it is local data at x, so $(f - s_i)'(x)$ through this chart lies in the support of $T(f, \Lambda)(x)$ Chapter15/Transversality · SBLocalization.mem_support_linSumIntr_iff and is onto on $T^R_x X$ by hypothesis. The chart step of Remark 15.3.6 (§XV.20) Chapter15/GoodPositionBranches · SBLocalization.isGeneralPositionGerm_subRestrict turns this into Part I's general position of $(f - s_i)|_O$: in the transported chart of $W|_O$ the intrinsic operator is the chart derivative of the branch, onto from $T_0 O \cap T^R_0$ means onto with $\ker + T^R_0 O = T_0 O$, which is Part I's chart criterion.
- *Good position from general position* Chapter15/GeneralPositionLocal · SBLocalization.isGoodPositionAt_of_isInGeneralPositionAt: general position at x with $\Lambda(f(x)) > 0$ gives good position at x. *Proof.* $T(f, \Lambda)(x)$ is onto, because each operator is already onto on the subspace $T^R_x X$, read in some chart with a presentation Chapter15/ControllingPairs · SBLocalization.exists_chart_presentation. Take any local structure on an open $O \ni x$ Chapter13/MultisectionSupport · SBLocalization.IsScPlusMultisection.exists_isLocalRepOn; each branch through $f(x)$ is in Part I's general position (previous lemma), hence in good position in a tame chart, by Part I's Lemma 5.26 Chapter5/Transversality · StrongBundle.IsGeneralPositionGerm.isGoodPositionGermTame, the branch being a tame sc-Fredholm section of $W|_O$ with x a zero.
- *From the branches back to the pair* Chapter15/GeneralPositionLocal · SBLocalization.isReducedOntoAtLevel_of_isGeneralPositionGerm: if, for a local structure on $O \ni y$ and a chart c around y with domain in

O, every branch through $f(y)$ is in Part I's general position at y, then (f,Λ) is in general position at y. *Proof.* The reduced tangent fibre does not depend on the chart and presentation `Chapter2/ReducedTangentIntrinsic · reducedTangentFiber_eq`, so it suffices to work in c with one presentation. An operator of the support is $(f-s_j)'(y)$ for a branch j through $f(y)$ (§XV.12). Its reduced restriction is onto `Chapter15/GeneralPositionLocal · SBLocalization.surjective_reduced_toIntr_of_isGeneralPositionGerm`, by the chart lemma: *every vector k of the fibre K_z has a preimage under the chart operator in $T^R_zO \cap T_zO$* `Chapter15/GeneralPositionLocal · SBLocalization.exists_reduced_preimage_of_isGeneralPositionGerm`. For this lemma, Part I's general position of $(f-s_j)|_O$ gives good position, hence a smooth solution submanifold in general position at y `Chapter5/GeneralPosition · exists_isGeneralPositionGerm_iff`; the first lemma gives $\ker +T^R = T$ in the restricted chart; the linearization is onto, so k has a preimage $v = a+b$ with a in the kernel and $b \in T^R$, and b is a preimage; and the derivative of the restricted chart is that of c `Chapter15/LocalIFT · SBLocalization.scDeriv_restrictTo_subRestrict`. Passing from the chart operator to the intrinsic one has two cases, as the intrinsic operator is defined by cases: if the chart operator takes values in the image of the fibre identification, the preimage b is carried to a reduced tangent vector with the right image; otherwise the intrinsic operator is 0, and the full operator being onto (§XV.10) forces $W_y = 0$, where any operator is onto.

Theorem 15.2.5, closing sentence (narrower) `Chapter15/GeneralPositionLocal · SBLocalization.theorem_15_2_5_generalPosition_hyp`. Let X be tame, f with tame germ data, $\Lambda(f(x)) > 0$ and (f,Λ) in general position at x. Then all conclusions of Theorem 15.2.5 hold on a natural representation $U(x)$, and (f,Λ) is in general position and in good position at every $y \in U(x)$ with $\Lambda(f(y)) > 0$. *Proof. Step 1.* General position at x gives good position at x, and Theorem 15.2.5 gives $U_1(x)$, the structure on O, the chart and all conclusions. *Step 2, openness of general position.* O is tame, an open subset of the tame X `Chapter11/FaceIntersectionCounterexample · MPolyfold.isTame_restrictOpen`. For each branch through $f(x)$, Part I's general position of $(f-s_i)|_O$ at x (the second lemma) is open along the solution set: Part I's Theorem 4.2.11 (3), in the form that a zero in general position of a tame sc-Fredholm section over a tame M-polyfold has an open neighbourhood W_i at whose zeros the section is in general position `Chapter5/GeneralPosition · exists_isOpen_isGeneralPositionGerm`. For the other branches $W_i = X$. *Step 3.* Shrink $U_1(x)$ into $\bigcap_i W_i$ `Chapter7/NaturalRep · EpGroupoid.exists_naturalRep_shrink`; the conclusions of Theorem 15.2.5 survive the shrinking, as in Step 7 of §XV.13. *Step 4.* At a support point $y \in U(x)$, every branch through $f(y)$ passes through $f(x)$ (last clause of Theorem 15.2.5) and $y \in W_i$, so it is in Part I's general position at y; the fourth lemma gives general position of the pair at y, and good position is clause (2) of Theorem 15.2.5. *The hypothesis of tameness* is that of Definition 15.3.5, which the text states over tame ep-groupoids, and it is what Part I's openness of general position needs. *Witness* `Chapter15/GoodPositionWitness · SBLocalization.theorem_15_2_5_generalPosition_hyp_witness`: the example of §XV.12, where the trivial ep-groupoid of $\mathbb{R}^n$ is tame `Chapter7/EpGroupoid · EpGroupoid.isTame_trivial_rn` and every pair is in general position `Chapter15/GeneralPositionBranched · SBLocalization.isInGeneralPosition_epSEP_zero`. Zero fibres: a consistency witness.

Witnesses for Theorem 15.2.5. The hypotheses in good position hold together at every point of the example of §XV.12 (§XV.15) `Chapter15/GoodPositionWitness · SBLocalization.theorem_15_2_5_hyp_witness`, and the conclusion is obtained there, with good position on all of $U(x)$ `Chapter15/GoodPositionWitness · SBLocalization.theorem_15_2_5_hyp_applies`. The example has no boundary and zero fibres, so it does not exercise the corner geometry for which Theorem 15.2.5 is made; Part I's Theorem 3.1.26, on which the tame form rests, has its own witnesses in Part III.

Remark 15.2.6 (pp. 690–691; nothing to formalize). Prose: with an oriented (f,o) the branches M_i inherit orientations $o_{i,y}$ from the surjective oriented $(f-s_i)'(y)$, recorded in the formal sum $\widehat{T}_{((f,o),\Lambda)}(y) = \sum \sigma_i \cdot (T_yM_i, o_{i,y})$. The local data it needs are in place: the M_i of Theorems 15.2.2 and 15.2.5 and the

surjective $(f - s_i)'(y)$ of (2) with the text's reading of §XV.12. The orientations themselves are Theorem 15.4.1 and Definition 15.4.2, formalized at a single point in §XV.34.

XV.17 The paragraph before Definition 15.3.1, Definition 15.3.1 and Remark 15.3.2 (2017: Definition 15.4, Remark 15.4)

§15.3 opens (p. 691) with the standing data of a perturbation problem: a strong bundle $(P : W \to X, \mu)$ over an ep-groupoid, an sc-Fredholm section functor f, and an auxiliary norm N (Definition 12.2.1, which is Definition 8.3.5). An auxiliary norm is defined on $W_{0,1}$; the text extends it by $N(h) = +\infty$ off $W_{0,1}$, so that "$N(f(x)) \le 1$" makes sense for every x. The formalization does not extend N. It keeps N on the level-$(0,1)$ part $W[1]$ and reads "$N(h) \le r$" as Part I's relation AuxLe: $h \in W_{0,1}$ and the value of N at h is at most r `Chapter5/Compactness · StrongBundle.AuxLe`. This is exactly the text's convention, a point with $N(h) = +\infty$ satisfying no inequality $N(h) \le r$.

Definition 15.3.1 (restated) `Chapter15/ControllingPairs · SBLocalization.ControlsCompactness`. *(N, U) controls the compactness of f* if

1. N is an auxiliary norm of (W, μ) (Definition 8.3.5: an auxiliary norm of the strong bundle, invariant under μ);
2. $U \subset X$ is open;
3. U is saturated;
4. $S_f = \{x : f(x) = 0_x\} \subset U$;
5. the closure in $|X|$ of $\pi(\{x \in U : N(f(x)) \le 1\})$ is compact, $\pi : X \to |X|$ the orbit map.

Readings. The orbit space "of a set" $A \subset X$ is its image $\pi(A)$. The text places the definition over an ep-groupoid with paracompact $|X|$. Paracompactness is not part of the formal definition, which is therefore more general; the statements that use paracompactness (the structurable addendum of Theorem 15.3.7, Theorem 15.3.9, Corollary 15.3.10) carry it as a hypothesis of their own. The text calls f an sc-Fredholm section functor; the formal predicate takes any f, and the theorems that use it supply the Fredholm property.

Monotonicity `Chapter15/ControllingPairs · SBLocalization.ControlsCompactness.mono`. If (N, U) controls the compactness of f and $U' \subset U$ is a smaller saturated open set still containing S_f, then (N, U') controls it. *Proof.* Clauses (1)–(4) for U' are the hypotheses. For (5): $\{x \in U' : N(f(x)) \le 1\} \subset \{x \in U : N(f(x)) \le 1\}$, so the closure of its image lies in the closure of the larger image, a compact set; a closed subset of a compact set is compact. The lemma is used wherever a proof shrinks the controlling neighbourhood.

The paragraph before Definition 15.3.1 (same) `Chapter15/ControllingPairs · SBLocalization.exists_controlsCompactness`. *Statement.* For an sc-Fredholm section functor f with $|S_f| = \pi(S_f)$ compact and any auxiliary norm N, there is a U with (N, U) controlling the compactness of f. The text says this follows from "the discussion in Section 12.4".

Proof. It is Theorem 12.4.2, the implication (2) $\Rightarrow$ (3), of Part XII: an sc-Fredholm section functor with compact solution set is proper$_{<\infty}$, that is, for every auxiliary norm N there is a saturated open $U \supset S_f$ such that $\mathrm{cl}_{|X|}\,\pi(\{x \in U : N(f(x)) \le C\})$ is compact for every $0 < C < \infty$ `Chapter12/CompactnessEp · EpStrongBundle.isProperLtInftyFunctor_of_hasCompactSolutionSetEp` `Chapter12/CompactnessEp · EpStrongBundle.IsProperLtInftyFunctor`. The formal proof then takes $C = 1$. The proof of the

implication, as Part XII retells it, runs in four steps, and we recall it because it is the whole content of the paragraph.

Step 1, the local step. At each zero x of f the local step of Theorem 5.2.2 gives an open $V(x) \ni x$ such that $\mathrm{cl}\{y \in V(x) : N(f(y)) \le C\}$ is compact for every $C > 0$ `Chapter12/CompactnessEp · exists_nhds_isCompact_closure_auxLe`; this uses only that f, as a section of the object M-polyfold, is sc-Fredholm.

Step 2, a finite cover. The orbit map is open (Proposition 7.1.8, Part VII) `Chapter7/Basic · EpGroupoid.proposition_7_1_8`, so the sets $\pi(V(x))$, $x \in S_f$, are an open cover of the compact $|S_f|$; finitely many, $\pi(V(x_1)), \dots, \pi(V(x_m))$, suffice. Let O be their union and $U = \pi^{-1}(O)$: it is open (continuity of π), saturated (a preimage under π), and contains S_f.

Step 3, invariance. If $y \in U$ with $N(f(y)) \le C$, then $\pi(y) = \pi(y')$ for some $y' \in V(x_i)$, that is, there is a morphism $\varphi : y \to y'$. Since f is a section functor and N is μ-invariant, $N(f(y')) = N(\mu(\varphi, f(y))) = N(f(y)) \le C$ `Chapter12/CompactnessEp · EpStrongBundle.auxLe_tgt_of_auxLe_src`.

Step 4, compactness. Hence $\pi(\{y \in U : N(f(y)) \le C\})$ lies in $K = \bigcup_i \pi(\mathrm{cl}\{y \in V(x_i) : N(f(y)) \le C\})$, a finite union of continuous images of compact sets, compact, and closed because $|X|$ is Hausdorff. The closure of the image lies in K and is compact.

Departure from the text. The text's proof of Theorem 12.4.2 shrinks to neighbourhoods with the natural action and uses $\mathrm{cl}_{|X|}|U| = |\mathrm{cl}_X U|$; neither is needed, because the closure lies in the finite union K. The paracompactness of $|X|$, which Theorem 12.4.2 assumes, is not used `Chapter12/CompactnessEp · EpStrongBundle.theorem_12_4_2`.

Remark 15.3.2 (nothing to formalize). The remark says that the construction of perturbations needs sc-smooth bump functions in general, and that geometric constructions may replace them at the price of checking compactness by hand. It is a comment. In the formalization bump functions enter as a hypothesis exactly where perturbations are built: Theorem 15.3.7 assumes that X admits sc-smooth bump functions in the pointwise reading (§XV.21), and the cylinder $[0,1] \times X$ of Corollary 15.3.10 inherits them from X `Chapter15/CubeEp · EpGroupoid.admitsBumpFunctionsPointwise_cubeProd` (§XV.30). The sentence after Definition 15.3.1, "we also assume that X admits sc-smooth bump functions", is likewise read as a hypothesis of the theorems that construct perturbations, not as part of any definition.

XV.18 Definition 15.3.3 (2017: 15.5) and the example after it

Definition 15.3.3 (same) `Chapter15/ControllingPairs · SBLocalization.IsAdmissible`. An (N, U)-*admissible perturbation* for f is a function $\Lambda : W \to \mathbb{Q}^+$ such that

1. Λ is an sc$^+$-multisection (Definition 13.2.1, in the 2021 form with local section structures, Part XIII);
2. $N(\Lambda)(x) \le 1$ for every $x \in X$, where $N(\Lambda)(x)$ is the pointwise norm of Definition 13.2.3, the largest value of N on the finite set $\mathrm{supp}(\Lambda)(x) = \{w \in W_x : \Lambda(w) > 0\}$ `Chapter13/MultisectionSupport · SBLocalization.pointwiseNorm`;
3. $\{x \in X : \exists t \in [-1,1],\ (t\Lambda)(f(x)) > 0\} \subset U$, where $t\Lambda$ is the scalar multiple of Definition 13.2.10: $(0\Lambda)(w) = 1$ if w is a zero vector and 0 otherwise, and $(t\Lambda)(w) = \Lambda(w/t)$ for $t \neq 0$ `Chapter13/MultisectionAlgebra · SBLocalization.multisectionSmul`.

Readings. The text's standing data, f sc-Fredholm with compact $|S_f|$ and (N, U) controlling compactness, are not part of the predicate; they are hypotheses of the theorems that use it (Theorem 15.3.9, the

boundary conditions of Corollary 15.3.10). The pointwise norm is defined as a supremum; for an sc$^+$-multisection it is attained, the support over a point being finite and nonempty, and the points of the support lie in $W_{0,1}$, where N is defined (Part XIII). Condition (3) with $t = 0$ asks that $S_f \subset U$, since $(0\Lambda)(f(x)) > 0$ exactly when $f(x) = 0_x$; with $t = \pm 1$ it asks that the support of $\Lambda \circ f$ and of $(-\Lambda) \circ f$ lie in U. The interval $[-1, 1]$ is what the cobordism argument of Corollary 15.3.10 (3) needs: perturbations $t\Lambda$ along a path stay inside U.

The example after Definition 15.3.3 (same) `Chapter15/ControllingPairs · SBLocalization.isAdmissible_of_domSupp_subset`. *Statement.* Let f be a section with $S_f \subset U$, and Λ an sc$^+$-multisection with $N(\Lambda) \leq 1$ whose domain support lies in U. Then Λ is (N, U)-admissible. The domain support is dom-supp$(\Lambda) = \mathrm{cl}_X\{x : \exists w \in W_x \setminus \{0_x\},\ \Lambda(w) > 0\}$ (Definition 13.2.2 (1)) `Chapter13/MultisectionSupport · SBLocalization.domSupp`.

Proof. Conditions (1) and (2) are hypotheses; condition (3) is the content, and it goes in three steps.

Step 1, off the domain support Λ sees only the zero vector `Chapter15/ControllingPairs · SBLocalization.eq_zero_of_not_mem_domSupp`. If $x \notin$ dom-supp(Λ) and $w \in W_x$ is not 0_x, then $\Lambda(w) = 0$: otherwise x would lie in the set whose closure is the domain support.

Step 2, the same for every scalar multiple `Chapter15/ControllingPairs · SBLocalization.eq_fiberZero_of_multisectionSmul_pos`. If $P(w) \notin$ dom-supp(Λ) and $(t\Lambda)(w) > 0$ for some real t, then w is the zero vector of its fibre. For $t = 0$ this is the definition of 0Λ. For $t \neq 0$, $(t\Lambda)(w) = \Lambda(t^{-1}w)$, with $t^{-1}w$ computed in the fibre; if $w \neq 0$ then $t^{-1}w \neq 0$ (multiply back by t), so $\Lambda(t^{-1}w) = 0$ by Step 1, a contradiction.

Step 3. Let $x \notin U$ with $(t\Lambda)(f(x)) > 0$ for some $t \in [-1, 1]$. Since dom-supp$(\Lambda) \subset U$, $x \notin$ dom-supp(Λ), and $P(f(x)) = x$ because f is a section; by Step 2, $f(x) = 0_x$, so $x \in S_f \subset U$, a contradiction.

The text's argument is Step 1 and Step 3 for $t = 1$; Step 2 makes the argument cover every $t \in [-1, 1]$, including $t = 0$, where 0Λ is the multisection of the zero section and the claim is $S_f \subset U$. Only the section property of f and $S_f \subset U$ are used: neither the Fredholm property nor the control of compactness enters. Witness of the definition: the zero multisection, whose domain support is empty and whose pointwise norm is 0 (§XV.21), is admissible for every controlling pair by this example.

XV.19 The products remark after Definition 15.3.3, and Remark 15.3.4: product ep-groupoids and product strong bundles

After Definition 15.3.3 (pp. 692–693) the text observes that admissible perturbations "behave well under products": for two problems (W, f, N, U, Λ) and $(W', f', N', U', \Lambda')$ it takes the product $f \times f'$ as an sc-Fredholm section of $W \times W' \to X \times X'$, the auxiliary norm $(N \times N')(h, h') = \max\{N(h), N'(h')\}$, the product multisection $(\Lambda \times \Lambda')(h, h') = \Lambda(h)\Lambda'(h')$, and checks that $\Lambda \times \Lambda'$ is admissible for $(N \times N', U \times U')$. Remark 15.3.4 adds that the domain support of $\Lambda \times \Lambda'$ lies in $(U \times X') \cup (X \times U')$, not necessarily in $U \times U'$. The text takes the product ep-groupoid, the product strong bundle and its structure map for granted. The formalization builds them: the product ep-groupoid (extra, row V15.17), the product strong bundle of Part I (restated, V15.53), products of sections (same, V15.54), the product over the product ep-groupoid with $\mu \times \mu'$ (same, V15.55), and $N \times N'$ as an auxiliary norm (same, V15.56). What remains of the remark, the sc-Fredholm property of $f \times f'$ and the multisection $\Lambda \times \Lambda'$ with its admissibility and domain support, is gap G.160 (§XV.38). The product ep-groupoid is also the

base of the cylinder $[0,1]^n \times X$ of Corollary 15.3.10 (§XV.30).

The product ep-groupoid (extra) Chapter15/ProductEp · EpGroupoid.prod. *Statement.* For ep-groupoids X, X', the groupoid with objects $X \times X'$ and morphisms $\mathbf{X} \times \mathbf{X}'$, all structure maps (source, target, composition, unit, inverse) taken componentwise Chapter15/ProductEp · GroupoidStr.prod, and the product M-polyfold structures on objects and morphisms (Exposition Lemma 4.D, Part II), is an ep-groupoid (Definition 7.1.3, Part VII). The groupoid axioms hold componentwise. *Proof* of the four conditions of Definition 7.1.3.

(1)–(2), the étale property and the smooth structure maps. Products of sc-smooth maps are sc-smooth on products of open sets: $f \times g = (f \circ \mathrm{pr}_1, g \circ \mathrm{pr}_2)$, a pair of composites with the sc-smooth projections Chapter15/ProductEp · MPolyfold.IsScSmoothOn.prodMap. Hence a product of sc-diffeomorphisms between open sets is one, with the product of the inverses as inverse Chapter15/ProductEp · MPolyfold.IsScDiffeoOn.prodMap, and a product of local sc-diffeomorphisms is one: at (p_1, p_2) take the product of the two local inverses Chapter15/ProductEp · MPolyfold.IsLocalScDiffeo.prodMap. So $s \times s'$ and $t \times t'$ are local sc-diffeomorphisms, and the unit and inverse maps, products of sc-smooth maps on univ $\times$ univ, are sc-smooth.

(3), properness. At (x, x') take the neighbourhoods $V \ni x$, $V' \ni x'$ of condition (3) for X and X', with $t : s^{-1}(\mathrm{cl}\, V) \to X$ and $t' : s'^{-1}(\mathrm{cl}\, V') \to X'$ proper. For $V \times V'$, the closure of a product is the product of the closures, so $(s \times s')^{-1}(\mathrm{cl}(V \times V')) = s^{-1}(\mathrm{cl}\, V) \times s'^{-1}(\mathrm{cl}\, V')$, and $t \times t'$ restricted to it is proper: a product of proper maps, composed with the homeomorphism between a product of subsets and the subset of the product Chapter15/ProductEp · isProperMap_domRestrict_prod Chapter15/ProductEp · EpGroupoid.prod_exists_isProperMap.

(4), sc-smooth composition. Condition (4) asks that composition be sc-smooth on the fibred product $\mathbf{X}\,{}_s\!\times_t \mathbf{X}$; Part VII proves it equivalent to its sheet form: for every sheet σ of s (a local inverse of s on an open V), the map $\psi \mapsto m(\sigma(t(\psi)), \psi)$ is sc-smooth on $t^{-1}(V)$ Chapter7/EpGroupoid · isScSmoothComp_iff_sheet. The formal proof checks the sheet form for the product Chapter15/ProductEp · EpGroupoid.prod_isScSmoothCompSheet. Let σ be a sheet of $s \times s'$ over V, and $\psi_0 \in (t \times t')^{-1}(V)$. Take sheets h_1 of s near the first component of $\sigma(t(\psi_0))$, defined on U_1, and h_2 of s' near the second, on U_2; let O be the open set of ψ near ψ_0 with $\sigma(t(\psi)) \in U_1 \times U_2$. On O, $s(\sigma(t(\psi))_1) = t(\psi_1)$, and since h_1 is a left inverse of s on U_1, $\sigma(t(\psi))_1 = h_1(t(\psi_1))$; likewise for the second component. So on O the map is $\psi \mapsto (m(h_1(t\psi_1), \psi_1), m'(h_2(t'\psi_2), \psi_2))$, a pair of maps that are sc-smooth by the sheet form of (4) for X and X', composed with the projections. Sc-smoothness is local, which concludes.

Consequences. The projections are sc-smooth functors Chapter15/ProductEp · EpGroupoid.prodFst Chapter15/ProductEp · EpGroupoid.prodSnd. If X and X' are tame, so is $X \times X'$, with $d_{X\times X'}(x, x') = d_X(x) + d_{X'}(x')$ Chapter15/ProductEp · EpGroupoid.isTame_prod Chapter15/ProductEp · EpGroupoid.degIndex_prod, from the M-polyfold statement Chapter2/FibredProduct · MPolyfold.isTame_prod. Two objects are isomorphic iff their components are: a morphism of the product is a pair of morphisms Chapter15/ProductEp · EpGroupoid.prod_π_eq_π_iff. *Reading.* The type of ep-groupoids requires paracompact object and morphism spaces; on the products these are instances that always hold, M-polyfolds being metrizable Chapter2/FibredProduct · MPolyfold.paracompactSpace_prod.

The model level: products of strong bundle maps and retracts. A strong bundle chart of W takes values in $E \lhd F$, pairs (base, fibre); for the product the natural model is $(E \oplus E') \lhd (F \oplus F')$, base first. The two are related by the swap $((a, a'), (b, b')) \mapsto ((a, b), (a', b'))$ Chapter15/ProductStrongBundle · bundleSwap, which on every level is a continuous linear isomorphism, an sc-operator Chapter15/ProductStrongBundle · ScBanach.bundleSwapOp. The product of local maps Φ, Φ' is $\Phi \times \Phi' :=$ swap $\circ$

$(\Phi \times \Phi') \circ \mathrm{swap}$ Chapter15/ProductStrongBundle · prodBundleMap Chapter15/ProductStrongBundle · prodBundleMap_eq, sc-smooth on $(U \times U') \lhd (F \oplus F')$ when Φ, Φ' are, as a composite of the product of sc-smooth maps with two sc-operators Chapter15/ProductStrongBundle · isScSmooth_prodBundleMap.

Products of strong bundle maps (Definition 2.6.1) Chapter15/ProductStrongBundle · IsStrongBundleMap.prod. Each clause of the definition is checked componentwise. $\Phi \times \Phi'$ maps $(U \times U')\lhd$ into $(V \times V')\lhd$; its base part does not depend on the fibre variable; it is linear in the fibre; it preserves the double filtration, because a pair lies on level m of $E \oplus E'$ iff both entries do Chapter15/ProductStrongBundle · ScBanach.mem_range_prod_toBase; it is sc-smooth on $\lhd$ by the previous paragraph. For the shifted bundle $\lhd[1]$ one needs that the $[1]$-version of the product is the product of the $[1]$-versions: the lift to level 1 of a pair of level-1 points is the pair of the lifts Chapter15/ProductStrongBundle · ScBanach.invFun_prod_toBase_one Chapter15/ProductStrongBundle · shiftFiber_prodBundleMap, and the $[1]$-maps are sc-smooth by the same composition.

Retractions and retracts (Definitions 2.6.1, 2.6.2). For strong bundle retractions R, R', $R \times R'$ is idempotent componentwise, so it is a strong bundle retraction Chapter15/ProductStrongBundle · IsStrongBundleRetraction.prod; its base retraction is $r \times r'$ Chapter15/ProductStrongBundle · baseRetraction_prod, with retract the product of the base retracts Chapter15/ProductStrongBundle · retract_baseRetraction_prod; and its image is the swap preimage of $K \times K'$, $K = R(U \lhd F)$ Chapter15/ProductStrongBundle · image_prodBundleMap. Hence $\mathrm{swap}^{-1}(K \times K')$ is a local strong bundle retract of $(C \times C') \lhd (F \oplus F')$ Chapter15/ProductStrongBundle · IsStrongBundleRetract.prod. Sc-smooth maps between retracts multiply in the same way: $T \times T'$ is the swap, the product $T \times T'$ of retract maps, and the swap back, three sc-smooth maps between retracts Chapter15/ProductStrongBundle · IsScSmoothRetractMap.prodBundleMap. The $[1]$-retract of $\mathrm{swap}^{-1}(K \times K')$ is $\mathrm{swap}^{-1}(K[1] \times K'[1])$ Chapter15/ProductStrongBundle · strongShiftOne_bundleSwap_preimage.

The product strong bundle (restated) Chapter15/ProductBundle · StrongBundle.prod. *Statement.* For strong bundles $P : W \to X$ and $P' : W' \to X'$ over M-polyfolds, $P \times P' : W \times W' \to X \times X'$ is a strong bundle (Definition 2.6.5), with the atlas of products of charts. *Construction.*

The fibres. The fibre over (x, x') is in bijection with $P^{-1}(x) \times P'^{-1}(x')$ Chapter15/ProductBundle · prodFiberEquiv; the vector space structure is transported along the bijection, which then is a topological linear isomorphism Chapter15/ProductBundle · prodFiberCLE. A product of Banachable spaces is Banachable Chapter15/ProductBundle · IsBanachable.prod, and Banachability passes along topological linear isomorphisms Chapter15/ProductBundle · IsBanachable.of_equiv.

The charts. For charts Φ of W over φ and Φ' of W' over φ', the product chart is $y \mapsto \mathrm{swap}(\Phi(y_1), \Phi'(y_2))$ over $\varphi \times \varphi'$, with fibre model $F \oplus F'$, domain $U \times U'$ and strong bundle retraction $R \times R'$ Chapter15/ProductBundle · StrongBundleChart.prod; its inverse is the pair of inverses after the swap Chapter15/ProductBundle · StrongBundleChart.prodPartialEquiv, it covers $\varphi \times \varphi'$, and it is linear on fibres, componentwise. Its image is $\mathrm{swap}^{-1}(K \times K')$ Chapter15/ProductBundle · StrongBundleChart.prod_K. *Compatibility.* The overlap of two product charts is the swap preimage of the product of the overlaps Chapter15/ProductBundle · StrongBundleChart.overlap_prod, and the transition map is the product of the transition maps Chapter15/ProductBundle · StrongBundleChart.transition_prod. Compatibility (Definition 2.6.4) asks four sc-smoothness statements, the transition maps and their inverses on $[0]$ and on $[1]$, and two level-preservation statements. The first four are the product of retract maps of the previous paragraph, on $[1]$ after identifying the $[1]$-map of the product with the product of the $[1]$-maps; the last two hold componentwise Chapter15/ProductBundle · StrongBundleChart.Compatible.prod. *The atlas* consists of the products $\Phi \times \Phi'$ of charts of the two atlases; any two are compatible by what was just shown, and they cover $W \times W'$ Chapter15/ProductBundle · StrongBundle.prodAtlas Chapter15/ProductBundle · StrongBundle.prod_mem_charts. $W \times W'$ is

paracompact, $W[0]$ and $W'[0]$ being metrizable Chapter15/ProductBundle · StrongBundle.paracompactSpace_prod. *Restated*, because the text does not describe the structure; the atlas of products of charts is the one the M-polyfold product of Part II uses.

The levels. As M-polyfolds, $(W \times W')[0]$ and $W[0] \times W'[0]$ coincide: the identity is sc-smooth in both directions, being the swap in the charts $\Phi \times \Phi'$ and $\Phi[0] \times \Phi'[0]$ Chapter15/ProductBundleLevels · StrongBundle.isScSmoothMap_id_prod_zero Chapter15/ProductBundleLevels · StrongBundle.isScSmoothMap_id_prod_zero_symm. The $(0,1)$-part is the product, $(W \times W')_{0,1} = W_{0,1} \times W'_{0,1}$ Chapter15/ProductBundleLevels · StrongBundle.mem_oneSet_prod, since in a product chart the level-1 lift is the swap of the pair of lifts Chapter15/ProductBundleLevels · StrongBundleChart.liftOne_prod. With their own topologies, $(W \times W')[1]$ and $W[1] \times W'[1]$ are homeomorphic Chapter15/ProductBundleLevels · StrongBundle.prodOneHomeomorph, the right side paracompact Chapter15/ProductBundleLevels · StrongBundle.paracompactSpace_prod_one, and the homeomorphism and its inverse are sc-smooth, again the swap in the $[1]$-charts Chapter15/ProductBundleLevels · StrongBundle.isScSmoothMap_prodOneHomeomorph Chapter15/ProductBundleLevels · StrongBundle.isScSmoothMap_prodOneHomeomorph_symm.

Products of strong bundle maps over maps of the bases (§8.3's strong bundle maps). Products of sc-smooth maps of total spaces are sc-smooth on $[0]$ Chapter15/ProductBundleMap · StrongBundle.isScSmoothMap_prodMap_zero and, through the homeomorphism of the $[1]$-levels, on $[1]$ Chapter15/ProductBundleMap · StrongBundle.isScSmoothMap_prodMap_one Chapter15/ProductBundleMap · StrongBundle.oneRestrict_prodMap. If Φ covers g and Φ' covers g', then $\Phi \times \Phi'$ is a strong bundle map covering $g \times g'$: it covers componentwise, is linear on fibres, maps $(W_1 \times W_1')_{0,1}$ into $(W_2 \times W_2')_{0,1}$ by the product formula for the $(0,1)$-parts, and is sc-smooth on $[0]$ and $[1]$ Chapter15/ProductBundleMap · StrongBundle.IsStrongBundleMap.prod.

Products of sections (same). $f \times f'$ is a section of $P \times P'$ Chapter15/ProductBundle · IsSection.prodMap. *Sc-smooth* Chapter15/ProductBundle · StrongBundle.IsScSmoothSection.prod: near any point p, an sc-smooth section has a chart representative: a chart φ of the base around p_1, a strong bundle chart Φ around $f(p_1)$, and an open $V \ni p_1$ on which $\Phi \circ f \circ \varphi^{-1}$ is an sc-smooth map between retracts Chapter15/ProductBundle · StrongBundle.exists_chart_rep. Do the same for f' at p_2; on $V \times V'$ the representative of $f \times f'$ in the product charts is the swap composed with the product of the two representatives, sc-smooth between retracts. *Sc⁺* Chapter15/ProductBundle · StrongBundle.IsScPlusSection.prod: in a product chart the fibre values lie on level 1 because both components do, and the representative into the $[1]$-retract $\mathrm{swap}^{-1}(K[1] \times K'[1])$ is again a swap composed with the product of the $[1]$-representatives.

Over the product ep-groupoid (same) Chapter15/ProductEpBundle · EpStrongBundle.prod. *Statement.* For strong bundles (W, μ) over X and (W', μ') over X', $(W \times W', \mu \times \mu')$ is a strong bundle over $X \times X'$ (Definition 8.3.1), with $(\mu \times \mu')((\varphi, \varphi'), (w, w')) = (\mu(\varphi, w), \mu'(\varphi', w'))$ Chapter15/ProductEpBundle · EpStrongBundle.prod_μ. *Proof.* The structure map is defined on the pull-back $(\mathbf{X} \times \mathbf{X}')_{s \times s'} \times_{P \times P'} (W \times W')$, a strong bundle over the morphism space; $\mu \times \mu'$ is a map on the product of the two pull-backs. The first step identifies the two. The splitting $((\varphi, \varphi'), (w, w')) \mapsto ((\varphi, w), (\varphi', w'))$ Chapter15/ProductEpBundle · prodPullbackSplit, with inverse the joining map Chapter15/ProductEpBundle · prodPullbackJoin, is a strong bundle map covering the identity of $\mathbf{X} \times \mathbf{X}'$, on $[0]$ and on $[1]$ Chapter15/ProductEpBundle · isStrongBundleMap_prodPullbackSplit: each of its two components is sc-smooth into its pull-back by the universal property of the pull-back (a map into a pull-back is sc-smooth when its two projections are), the projections being the projections of the product composed with the identification $(W \times W')[0] = W[0] \times W'[0]$ above, and likewise on $[1]$ with the homeomorphism of the $[1]$-levels. Its inverse is sc-smooth by the same argument, so it is an sc-diffeomorphism and in particular a local sc-diffeomorphism Chapter15/ProductEpBundle · isLocalScDiffeo_prodPullbackSplit. Then $\mu \times \mu' := (\mu \times \mu') \circ \mathrm{split}$

`Chapter15/ProductEpBundle · EpStrongBundle.prodμ` is: a strong bundle map covering $t \times t'$, as the composite of the splitting with the product of the strong bundle maps μ, μ'; surjective, by joining preimages; a local sc-diffeomorphism, as the composite of the splitting, the identity between the product strong bundle and the product M-polyfold on $[0]$, the product of the local sc-diffeomorphisms μ, μ', and the identity back; and it satisfies the unit and composition laws componentwise.

Section functors. If f and f' satisfy the functor condition $f(t\varphi) = \mu(\varphi, f(s\varphi))$, so does $f \times f'$, componentwise `Chapter15/ProductEpBundle · EpStrongBundle.IsFunctorialSection.prod`; products of sc-smooth section functors are sc-smooth section functors `Chapter15/ProductEpBundle · EpStrongBundle.IsScSmoothSectionFunctor.prod`, and products of sc⁺-section functors are sc⁺ `Chapter15/ProductEpBundle · EpStrongBundle.IsScPlusSectionFunctor.prod` (Definition 8.3.4 (1), (2)). The paracompactness instances on the pull-backs and products that the types require are produced by the lemmas above; they always hold.

$N \times N' = \max(N, N')$ **is an auxiliary norm** (same). *Definition* `Chapter15/ProductAuxNorm · StrongBundle.prodAuxNorm`: on $(W \times W')[1]$, $(N \times N')(w, w') = \max(N(w), N'(w'))$, read through the homeomorphism $(W \times W')[1] \cong W[1] \times W'[1]$; on a fibre, the level-$(0,1)$ fibre of the product is the product of the fibres `Chapter15/ProductAuxNorm · StrongBundle.prodOneFiberFst` `Chapter15/ProductAuxNorm · StrongBundle.prodOneFiberMk`, and the norm is the maximum of the norms of the components `Chapter15/ProductAuxNorm · StrongBundle.prodAuxNorm_toOne`. *Statement* `Chapter15/ProductAuxNorm · StrongBundle.isAuxNorm_prodAuxNorm`: if N, N' are auxiliary norms (Definition 5.1.1), so is $N \times N'$. *Proof*, clause by clause. *Continuity*: a maximum of continuous functions. *On each fibre a complete norm*: (i) if $\max(N(v_1), N'(v_2)) = 0$, both are 0, since both are non-negative, so $v_1 = 0$, $v_2 = 0$, and $v = 0$ `Chapter15/ProductAuxNorm · StrongBundle.prodOneFiber_ext`; (ii) homogeneity, $\max(|t|N(v_1), |t|N'(v_2)) = |t| \max(N(v_1), N'(v_2))$; (iii) the triangle inequality, each component's inequality bounded by the sum of the maxima; (iv) completeness: a sequence Cauchy for the maximum is Cauchy for each component, the components converge to a and b by completeness of N and N', and the sequence converges to the pair (a, b) for the maximum. *Condition (2) of Definition 5.1.1*: if the base points $P(w_k)$ converge to x and $(N \times N')(w_k) \to 0$, then both $N(w_{k,1}) \to 0$ and $N'(w_{k,2}) \to 0$ by squeezing between 0 and the maximum, condition (2) for N and N' gives $w_{k,1} \to 0_{x_1}$ in $W[1]$ and $w_{k,2} \to 0_{x_2}$ in $W'[1]$, and the inverse of the homeomorphism of the $[1]$-levels carries the pair to $w_k \to 0_x$ in $(W \times W')[1]$. *Over the ep-groupoid* `Chapter15/ProductAuxNorm · EpStrongBundle.isAuxNorm_prodAuxNorm` (Definition 8.3.5): in addition $N \times N'$ is invariant under $\mu \times \mu'$, because each component is invariant under its own structure map.

What is not formalized of the remark (gap G.160, §XV.38): (c) $f \times f'$ is sc-Fredholm with tame germ data; Part I has no product of sc-Fredholm germs, only the case of the cube $[0,1]^n$ as a parameter, which the cylinder uses (§XV.30); (d) $\Lambda \times \Lambda'$ as an sc⁺-multisection, from products of local section structures with weights $\sigma_i \sigma'_j$, the identity $(N \times N')(\Lambda \times \Lambda') = \max(N(\Lambda), N'(\Lambda'))$, the identity $t(\Lambda \times \Lambda') = (t\Lambda) \times (t\Lambda')$ and the admissibility for $(N \times N', U \times U')$, and Remark 15.3.4 on the domain support. The ingredient that the sections of the local structures multiply to sc⁺-sections is `IsScPlusSection.prod` above.

XV.20 Definition 15.3.5 and Remark 15.3.6 (2017: Definition 15.6, Remark 15.6): general position

Definition 15.3.5 (restated) `Chapter15/ControllingPairs · SBLocalization.IsInGeneralPosition`. *Statement.* (f, Λ) is *in general position* if for every $x \in X_1$ with $\Lambda(f(x)) > 0$, every operator L in the support of the formal

sum $T(f,\Lambda)(x) \in \mathrm{GrF}(x)$ (Definition 15.1.7, §XV.8), every chart φ of X around x and every presentation T of the partial quadrant C of its model ($C = T^{-1}([0,\infty)^k \times V)$), the restriction of $L : T_xX \to W_x$ to the reduced tangent space T^R_xX is surjective. T^R_xX is Part II's reduced tangent fibre (Definition 2.5.8), read in the chart φ and the presentation T `Chapter2/ReducedTangentIntrinsic · MPolyfold.reducedTangentFiber`.

Readings. (a) The text quantifies over $x \in \mathrm{supp}(\Lambda \circ f)$; the formal definition takes x in X_1, where $T(f,\Lambda)$ is defined. Nothing is lost, because the support lies in X_1 (below). (b) The text writes $T(f,\Lambda)(x) = \sum_i \sigma_i L_i$ with $\sigma_i > 0$; these L_i are the elements of the support of the formal sum, the operators with positive coefficient. (c) "T^R_xX (Definition 2.5.8)" is read in every chart and every presentation; since T^R_xX does not depend on them, one suffices (below). (d) The text works over a tame ep-groupoid; tameness is not part of the formal definition, and it enters the statements that need T^R_xX to be the right space, through Part I's results on tame M-polyfolds.

The support lies in X_1 `Chapter15/ControllingPairs · SBLocalization.mem_levelSet_one_of_pos`. *Statement.* For an sc-Fredholm section functor f and an sc$^+$-multisection Λ, $\Lambda(f(x)) > 0$ implies $x \in X_1$. *Proof.* Take a local section structure (s_i, σ_i) of Λ on an open $O \ni x$ (the 2021 form, Part XI). The count formula gives $\Lambda(f(x)) = \sum_{i : f(x) = s_i(x)} \sigma_i$; the sum is positive, so some i has $f(x) = s_i(x)$. The value $s_i(x)$ of an sc$^+$-section lies in $W_{0,1}$, and an sc-Fredholm section functor is regularizing: $x \in X_0$ and $f(x) \in W_{0,1}$ give $x \in X_1$ `Chapter12/CompactnessEp · EpStrongBundle.remark_12_1_1_regularizing_obj` (the remark after Definition 12.1.1, Part XII).

One chart suffices. Every level-1 point lies in a chart with a presentation of its partial quadrant `Chapter15/ControllingPairs · SBLocalization.exists_chart_presentation`. The reduced tangent fibre does not depend on the chart and the presentation (Proposition 2.4.10, Part II) `Chapter2/ReducedTangentIntrinsic · MPolyfold.reducedTangentFiber_eq`, so surjectivity on it, checked in one chart and presentation at each point, holds in all `Chapter15/ControllingPairs · SBLocalization.isInGeneralPosition_iff_exists`: given the check in (φ, T) and another pair (ψ, T'), rewrite the reduced fibre of (ψ, T') as that of (φ, T).

The reduced linearization. The text calls the restriction $T^R_{(f,\Lambda)}(x) = \sum_i \sigma_i L_i | T^R_xX$ the reduced linearization. Formally it is the push-forward of the formal sum along $L \mapsto L|T^R_xX$, in a chart and presentation `Chapter15/ControllingPairs · SBLocalization.reducedLinearization`. Two distinct operators may have the same restriction; their coefficients then add. With coefficients in $\mathbb{Q}^+$ nothing cancels, so the support of a push-forward is the image of the support `Chapter15/ControllingPairs · Finsupp.support_mapDomain_nnrat`: for $b = g(a)$ with a in the support, the coefficient of b is a sum of non-negative terms one of which is positive. Hence general position is the surjectivity of every operator of the reduced linearization `Chapter15/ControllingPairs · SBLocalization.isInGeneralPosition_iff_reducedLinearization`.

Witness `Chapter15/ControllingPairs · SBLocalization.isInGeneralPosition_witness`: over the trivial ep-groupoid of $\mathbb{R}^n$ with the bundle $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$, the zero section and the zero multisection (the multisection of the zero section, value 1 at zero vectors) are in general position, and $\mathrm{supp}(\Lambda \circ f)$ is all of $\mathbb{R}^n$. The fibres are 0, so every operator onto them is surjective. The witness shows that the all-charts form is satisfiable with nonempty support; it has zero fibres and is **weak** as a test of the condition.

Remark 15.3.6, first sentence (same) `Chapter15/ControllingPairs · SBLocalization.IsInGeneralPosition.surjective`. *Statement.* In general position, every operator of the support of $T(f,\Lambda)(x)$, $x \in \mathrm{supp}(\Lambda \circ f) \cap X_1$, is surjective. *Proof.* Choose a chart and a presentation at x; for $w \in W_x$ general position gives $\alpha \in T^R_xX$ with $L\alpha = w$, and $\alpha \in T_xX$. "Onto" is read operator by operator, as in Definition 15.2.1 (§XV.12); so general position implies transversality, which the proof of Theorem 15.3.7 uses (§XV.22).

Remark 15.3.6, second sentence (narrower; stronger in its range) Chapter15/GoodPositionBranches · SBLocalization.remark_15_3_6_goodPosition_hyp. *Statement.* Let f be an sc-Fredholm section functor with Part I's tame germ data, Λ an sc$^+$-multisection, (f,Λ) in general position and $\Lambda(f(x)) > 0$. Then (a) (f,Λ) is in good position at x (Definition 15.2.4, §XV.15); (b) for every local section structure (s_i,σ_i) of Λ on an open $O \ni x$ and every i with $s_i(x) = f(x)$, the section $(f - s_i)|_O$ of the restricted bundle $W|_O$ (§XV.10) is in general position at x in Part I's sense (Definition 5.3.9). The text states this for $x \in \partial X$, with "good position, in fact even in general position"; (b) is the reading of "even in general position", Definition 15.3.5 being "a natural extension" of Definition 5.3.9. The formal statement holds at every point of the support, on the boundary or not: stronger in that respect.

Proof. Four steps, the first two in a chart.

Step 1, the reduced surjectivity read in a chart Chapter15/GoodPositionBranches · SBLocalization.exists_reduced_preimage. Let c be a strong bundle chart around x with base chart φ, retraction r on U, fibre retract K, and z the level-1 point over $\varphi(x)$. Let L be a chart operator $E_0 \to F_0$ whose intrinsic operator $\Phi_x^{-1} \circ L \circ T\varphi$ (§XV.7) is onto W_x on $T_x^R X$. Then every k with $(\varphi(x),k) \in K$ is Lw for some w in the chart's reduced tangent space at z that also lies in the range of $Dr(z)$, the chart tangent space T_zO. The intrinsic operator is built from L only when all chart vectors are mapped into the range of the fibre identification; in that case the preimage $\alpha \in T_x^R X$ of $\Phi_x^{-1}(k)$ gives w, the chart vector of α, which lies in T_zO and, by the chart description of the reduced fibre, in the reduced tangent space. Otherwise the intrinsic operator is 0 by definition, surjectivity forces $W_x = 0$, and $w = 0$ serves.

Step 2, the chart step Chapter15/GoodPositionBranches · SBLocalization.isGeneralPositionGerm_subRestrict. *Statement.* Let s be sc$^+$ on an open O, $f(x) = s(x)$, and c a **tame** strong bundle chart of W **centred** at x ($\varphi(x) = 0$) with domain in O. If the intrinsic operator $(f - s)'(x)$ (§XV.7) is onto W_x on $T_x^R X$, then $(f - s)|_O$ is in general position at x in Part I's sense. *Proof.* Restrict c to a chart c' of $W|_O$, tame because c is Chapter15/LocalIFT · SBLocalization.scDeriv_restrictTo_subRestrict: in it the derivative at 0 of the principal part of $(f - s)|_O$ composed with the retraction is the chart operator $D((\hat{f} - \hat{s}) \circ r)(0)$ of W. The section $(f - s)|_O$ is tame sc-Fredholm (§XV.10) and vanishes at x. By Step 1 the linearization $\mathrm{Lin}(0)$ of $(f - s)|_O$ in c' maps the reduced tangent space onto the fibre K_0, in particular it is onto. Next, $\ker \mathrm{Lin}(0) + T_0^R = T_0O$: for $v \in T_0O$, $k = \mathrm{Lin}(0)v$ lies in the fibre of K over 0, because the derivative of the principal part composed with r is fixed by the fibre projection ρ at a zero; Step 1 gives a reduced w with $\mathrm{Lin}(0)w = k$; and $v = (v - w) + w$ with $v - w \in \ker \mathrm{Lin}(0)$. These two facts are Part I's chart criterion for general position, proved in Part I's chapter on general position Chapter5/CylinderPerturbation2021 · isGeneralPositionGerm_of_sup_eq, which concludes.

Step 3, every branch through $f(x)$ Chapter15/GoodPositionBranches · SBLocalization.isGeneralPositionGerm_branch. Let (s_i,σ_i) be a local structure on $O \ni x$ and $s_i(x) = f(x)$. The point x is smooth, being a zero of the regularizing section $f - s_i$ Chapter15/Transversality · SBLocalization.mem_smoothSet_of_eq, in particular in X_1. The tame germ data of f give a tame chart centred at x; restricted to O it stays tame and centred with domain in O. With the local structure and this chart as local data (§XV.8), $T(f,\Lambda)(x)$ is their formal sum, so the intrinsic operator $(f - s_i)'(x)$ is in its support, the branch passing through $f(x)$ Chapter15/Transversality · SBLocalization.mem_support_linSumIntr_iff Chapter15/LinearizationIntrinsic · SBLocalization.linearization_eq. General position makes it onto on $T_x^R X$ in this chart, and Step 2 applies.

Step 4, good position. Definition 15.2.4 asks three things at x. $\Lambda(f(x)) > 0$ is the hypothesis. $T(f,\Lambda)(x)$ is onto: $x \in X_1$ by the lemma above, and every operator of the support is onto by the first sentence. For some local structure on an open $O \ni x$, given by the sc$^+$-multisection, every branch through

$f(x)$ is in Part I's good position (Definition 3.6.6): by Step 3 it is in general position, and general position implies good position for a tame sc-Fredholm section at a zero, Part I's Lemma 5.26 `Chapter5/Transversality · StrongBundle.IsGeneralPositionGerm.isGoodPositionGermTame`, applied to $(f - s_i)|_O$, which is tame sc-Fredholm `Chapter15/LocalScPlus · SBLocalization.isScFredholmSectionTame_subRestrict` and vanishes at x `Chapter15/LocalScPlus · SBLocalization.isZeroAt_subSec_iff`.

Narrower by the inherited hypothesis: Part I's tame germ data of f, the hypothesis of all of §15.2 (§§XV.13–XV.16), inherited from Part I's Theorems 3.1.18 and 3.6.8, without which Theorem 3.6.8 does not hold as we read it (Part III). Here it supplies the tame chart centred at x of Step 2. Witness of all hypotheses together: the zero section of $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$ with the zero multisection, which has tame germ data `Chapter15/InteriorPerturbationWitness · SBLocalization.theorem_15_2_2_hyp_witness` and is in general position `Chapter15/GeneralPositionBranched · SBLocalization.isInGeneralPosition_epSEP_zero`; it has zero fibres (weak). No $d_X = 0$ is needed: unlike Remark 15.2.3 (§XV.14), the boundary points are reached through good position.

Remark 15.3.6, last sentence (narrower). The text concludes that $\Lambda \circ f$ is a tame branched ep⁺-subgroupoid. Three formal statements carry this.

Local branching `Chapter15/GeneralPositionBranched · SBLocalization.remark_15_3_6_localBranching_hyp`. *Statement.* Under the hypotheses of the second sentence, at every y with $\Lambda(f(y)) > 0$ the function $z \mapsto \Lambda(f(z))$ has a local branching structure in the sense of Definition 9.1.2 (2)–(4) (Part IX). *Proof.* By the second sentence (f, Λ) is in good position at y, so Theorem 15.2.5 (§XV.16) applies at y: it gives a natural representation $U(y)$, a local section structure (s_i, σ_i) and a chart, such that each $M_i = \{z \in U(y) : f(z) = s_i(z)\}$ is a smooth submanifold properly embedded in $U(y)$, the count $\Lambda(f(z)) = \sum_{i : f(z) = s_i(z)} \sigma_i$ holds on $U(y)$, and only branches through $f(y)$ meet f in $U(y)$. The branching structure is indexed by the branches through $f(y)$, with the sets M_j, which contain y, and the weights $\sigma_j > 0$. The count identity of Definition 9.1.2 is the count formula with the sum restricted to these branches: the terms of the other branches vanish on $U(y)$ by the last clause of Theorem 15.2.5.

Branched `Chapter15/GeneralPositionBranched · SBLocalization.remark_15_3_6_isBranchedEpSubgroupoid_hyp`. *Statement.* If moreover the orbit space $|\operatorname{supp}(\Lambda \circ f)|$ is paracompact, $\Lambda \circ f$ is a branched ep⁺-subgroupoid of X (Definition 9.1.2). *Proof.* Each clause of the definition: the values are non-negative rationals; $\Lambda \circ f$ is a functor, because f is a section functor and Λ is a functor, $\Lambda(f(t\varphi)) = \Lambda(\mu(\varphi, f(s\varphi))) = \Lambda(f(s\varphi))$ `Chapter15/GeneralPositionBranched · SBLocalization.isFunctorial_comp`; the support consists of smooth points, the tame germ data making $f - s_i$ regularizing `Chapter15/Transversality · SBLocalization.mem_smoothSet_of_pos`; the paracompactness of $|\operatorname{supp}|$ is the hypothesis; and the local branching structures are the previous statement. *The added hypothesis*, the paracompactness of the orbit space of the support, is Definition 9.1.2 (1), new in the 2021 edition, which the remark does not address; it is not derived from the text. It is automatic when $|\operatorname{supp}(\Lambda \circ f)|$ is compact, the situation of Theorem 15.3.7 (§XV.21); witness for $\mathbb{R}^n$ `Chapter9/Propositions · EpGroupoid.paracompactSpace_orbitSupp_trivial_rn`.

Tame `Chapter15/TameBranched · SBLocalization.remark_15_3_6_isTameBranched_hyp`. *Statement.* Under the same hypotheses $\Lambda \circ f$ is a branched ep⁺-subgroupoid and tame (Definition 9.3.6). *Proof.* Good position holds at every point of the support (second sentence), and the global form of Theorem 15.2.5 (§XV.16) `Chapter15/TameBranched · SBLocalization.theorem_15_2_5_isTameBranched_hyp` concludes: at each support point Theorem 15.2.5 with "tame" gives a tame local branching structure, a natural representation with the properness property whose sheets M_j carry a tame induced structure (Definition 2.5.18); forgetting the tameness gives the local branching structures of Definition 9.1.2, and the tame structures are Definition 9.3.6. Witness of the tame global form on $\mathbb{R}^n \times \mathbb{R}^0$, with support everything `Chapter15/TameWitness · SBLocalization.remark_15_2_3_isTameBranched_hyp_witness` (zero fibres, weak).

Narrower in all three only through the inherited tame germ data and, for the global forms, the paracompact support of Definition 9.1.2 (1). The text writes "tame branched ep⁺-groupoid", read as "ep⁺-subgroupoid". The compact form, under the hypotheses of Theorem 15.3.7, is its "in particular" (§XV.21), where compactness supplies the paracompactness.

XV.21 Theorem 15.3.7 (2017: 15.4): the statement and its "in particular"

Theorem 15.3.7 (pp. 693–698) is the existence theorem for perturbations in general position. Over a tame ep-groupoid with sc-smooth bump functions, it takes an sc-Fredholm section functor f with compact solution set $|S_f|$, a pair (N, U) controlling compactness, and a continuous functor $h : X \to (0, 1]$. It produces an sc⁺-multisection functor Λ with four properties, and then adds two claims: "in particular" $\Lambda \circ f$ is a compact, tame, branched ep⁺-subgroupoid, and Λ "can be taken to be structurable". The formalization states the theorem as two propositions, one with and one without "structurable", and proves both. The proof is told in §§XV.22–XV.25; the final theorems are in §XV.26.

Statement (explicit) `Chapter15/GeneralPositionExistence · SBLocalization.theorem_15_3_7_existence_statement`. Suppose: - X is tame; - X admits sc-smooth bump functions, in the pointwise reading of Part XII, which Theorem 12.3.2 (1) shows equivalent to bump functions on the object M-polyfold `Chapter12/BumpEp · EpGroupoid.theorem_12_3_2_1`; - f is an sc-Fredholm section functor with the tame germ data of §15.2, and $|S_f|$ is compact; - (N, U) controls compactness (Definition 15.3.1, §XV.17) `Chapter15/ControllingPairs · SBLocalization.ControlsCompactness`. That is, N is an auxiliary norm, U is an open saturated set containing S_f, and the orbit set of $\{x \in U : N(f(x)) \le 1\}$ has compact closure in $|X|$; - h is continuous, takes the same value at the source and the target of every morphism, and satisfies $0 < h \le 1$.

Then there is an sc⁺-multisection Λ with: - (1) $N(\Lambda)(x) < h(x)$ for every x, where $N(\Lambda)(x)$ is the pointwise norm of Part XIII (Definition 13.2.3), the largest $N(w)$ over the $w \in W_x$ with $\Lambda(w) > 0$; - (2) domain support in U; - (3) (f, Λ) transversal (Definition 15.2.1, §XV.12) `Chapter15/Transversality · SBLocalization.IsTransversal`; - (4) (f, Λ) in general position (Definition 15.3.5, §XV.20) `Chapter15/ControllingPairs · SBLocalization.IsInGeneralPosition`.

The structurable form `Chapter15/GeneralPositionBranched · SBLocalization.theorem_15_3_7_statement` is the same proposition with Λ structurable (Definition 13.3.6). The theorem with its addendum pairs the two: (1)–(4) under the hypotheses above, and the structurable form whenever X has a good system `Chapter15/GeneralPositionExistence · SBLocalization.theorem_15_3_7`.

Readings. - The text's "U … a saturated subset" is read as open and saturated, as in Definition 15.3.1. - A "continuous functor $h : X \to (0, 1]$" is read as a continuous function on objects that is constant along morphisms. This is a functor into the trivial category on $(0, 1]$. - (3) is "$T(f, \Lambda)$ is surjective on $\mathrm{supp}(\Lambda \circ f)$", i.e. every operator of the linearization of Definition 15.1.7 (§XV.8) is onto at every support point. - (4) is formalized as the reduced linearization being onto at every support point. This follows the first sentence of the proof: "Point (4) is equivalent to" that requirement. - "Structurable" is Definition 13.3.6.

Explicit: the only hypothesis not printed in the theorem is the tame germ data of f. It is inherited from §15.2 (§XV.16), where the boundary local perturbation needs it. The theorem itself uses no good system and no paracompactness of $|X|$.

"In particular", compact and branched (narrower) `Chapter15/GeneralPositionBranched · SBLocalization.`

theorem_15_3_7_in_particular_hyp. Let f be an sc-Fredholm section functor with tame germ data, and let (N, U) control compactness. Let Λ be an sc$^+$-multisection with $N(\Lambda) \leq 1$, domain support in U, and (f, Λ) in general position. Then $\Lambda \circ f$ is a branched ep$^+$-subgroupoid (Definition 9.1.2) with compact support (Definition 9.1.6 (2)).

Proof. 1. f is continuous, being an sc^0 section. 2. *The support is closed* Chapter15/GeneralPositionBranched · SBLocalization.isClosed_supp_comp. Near any point x_0, Λ has a local representation $(s_i, \sigma_i)_{i \in I}$ on an open $O \ni x_0$, with positive weights. On O, $\Lambda(w) = \sum_{i : s_i(y) = w} \sigma_i$ for $w \in W_y$. Since the weights are positive, $\Lambda(f(y)) > 0$ if and only if $f(y) = s_i(y)$ for some i Chapter15/GeneralPositionBranched · SBLocalization.pos_iff_exists_eq. So the complement of the support meets O in $O \cap \bigcap_i \{y : f(y) \neq s_i(y)\}$. Each set $\{f \neq s_i\}$ is open in O, because two continuous sections into a Hausdorff bundle disagree on an open set. Hence the complement is open. 3. *Its orbit set is closed* Chapter15/GeneralPositionBranched · SBLocalization.isClosed_orbitSupp_comp. The support is saturated: $f(\mathrm{tgt}\,\varphi) = \mu(\varphi, f(\mathrm{src}\,\varphi))$, and Λ is a functor, so $\Lambda \circ f$ is constant along morphisms. Hence the complement of $|\mathrm{supp}(\Lambda \circ f)|$ is the image of the complement of the support under the orbit map. The orbit map is open (Proposition 7.1.8) Chapter7/Basic · EpGroupoid.proposition_7_1_8, so this image is open. 4. *The support lies in the controlled set* Chapter15/GeneralPositionBranched · SBLocalization.supp_comp_subset_controlled. Let $\Lambda(f(x)) > 0$. - If $f(x) = 0$, then $x \in S_f \subseteq U$. - Otherwise Λ is positive at a non-zero vector over x, so x is in the domain support, hence in U.

In both cases $f(x)$ lies in $\mathrm{supp}(\Lambda)(x)$, so $N(f(x)) \leq N(\Lambda)(x) \leq 1$. 5. *Compactness* Chapter15/GeneralPositionBranched · SBLocalization.isCompact_orbitSupp_comp. $|\mathrm{supp}(\Lambda \circ f)|$ is a closed subset of the compact closure that (N, U) provides. 6. *Branched.* A compact space is paracompact. This gives the paracompact support that Definition 9.1.2 (1) asks for, and Remark 15.3.6 (§XV.20) supplies the local branching structures Chapter15/GeneralPositionBranched · SBLocalization.remark_15_3_6_isBranchedEpSubgroupoid_hyp.

Only (1) (with $h \leq 1$), (2) and (4) are used. (3) follows from (4) Chapter15/ControllingPairs · SBLocalization.IsInGeneralPosition.surjective. *Narrower*: the tame germ data are inherited from §15.2, and here they enter the conclusion, through good position at every support point (§XV.16).

"In particular", tame (narrower) Chapter15/TameBranched · SBLocalization.theorem_15_3_7_in_particular_tame_hyp. Under the same hypotheses, $\Lambda \circ f$ is moreover a tame branched ep$^+$-subgroupoid (Definition 9.3.6).

Proof. The first two conclusions are the previous theorem. Tameness is the tame form of Remark 15.3.6 (§XV.20) Chapter15/TameBranched · SBLocalization.remark_15_3_6_isTameBranched_hyp, applied with the paracompactness that the compact support gives.

The zero multisection. Suppose (f, Λ_0) is already in general position, where Λ_0 is the trivial multisection (weight 1 at the zero vector). Then Λ_0 has all the conclusions of the structurable form, for every $h > 0$ and every U, provided $|X|$ is paracompact (needed for "structurable") Chapter15/GeneralPositionBranched · SBLocalization.theorem_15_3_7_of_isInGeneralPosition_zero: - its pointwise norm is 0 Chapter15/GeneralPositionBranched · SBLocalization.pointwiseNorm_zeroMultisection; - its domain support is empty Chapter15/GeneralPositionBranched · SBLocalization.domSupp_zeroMultisection.

On the bundle $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$, every pair is in general position, because every operator onto the zero fibre is surjective Chapter15/GeneralPositionBranched · SBLocalization.isInGeneralPosition_epSEP_zero. So the structurable form holds there with $\Lambda = \Lambda_0$ Chapter15/GeneralPositionBranched · SBLocalization.theorem_15_3_7_statement_epSEP_zero. This instance shows that the statement is not vacuous. It is weak: the fibres are zero and there is no boundary.

XV.22 Proof of Theorem 15.3.7, I: linear families, (15.1), and the assembly

The text's proof: - builds a family Λ_t, $t \in \mathbb{R}^{\bar\ell}$, of multisections from local pieces at the points of S_f; - shows that the parametrized problem is onto on reduced tangent spaces at $\{0\} \times S_f$ ((15.1)); - uses the compactness (15.2) to stay near S_f for small $|t|$; - picks a small regular value t_0 of the projection to the parameter space, by Sard's theorem on the intersections of faces.

The formalized proof of (1)–(4) `Chapter15/GeneralPositionExistence · SBLocalization.theorem_15_3_7_existence` follows this plan in five steps: - (a) at every point of S_f, small sections with (15.1) near that point ("seeds"; §§XV.23–XV.24); - (b) from the seeds, a family good on a saturated neighbourhood of each point of S_f (§XV.23); - (c) by compactness of $|S_f|$, one family good on a neighbourhood of S_f (this subsection); - (d) for this family, general position for almost every small t (§XV.25); - (e) the choice of t (this subsection).

The structurable form `Chapter15/GeneralPositionGoodSystem · SBLocalization.theorem_15_3_7_of_goodSystem` has the same five steps with structurable families. This subsection gives the objects the proof works with and steps (c) and (e).

Linear combinations of sections `Chapter15/ParamFamily · SBLocalization.paramSec`. For sections $s_1, \dots, s_\ell$ and $t \in \mathbb{R}^\ell$, the section $\sum_j t_j s_j$ is taken fibrewise, in the linear structure of W_y: - it is a section, and an sc⁺-section when each s_j is one; - concatenating the parameters adds the combinations: $\sum_j t_j s_j + \sum_k t'_k s'_k$ is the combination of the concatenated sections at the concatenated parameter `Chapter15/ParamFamily · SBLocalization.paramSec_append`; - $N(\sum_j t_j s_j(y)) \le \sum_j |t_j|\, N(s_j(y))$, by subadditivity and homogeneity of the auxiliary norm on the fibres `Chapter15/ParamFamily · SBLocalization.normW_paramSec_le`.

Linear families `Chapter15/ParamFamily · SBLocalization.IsLinearFamily`. A family $t \mapsto \Lambda_t$ of multisections, $t \in \mathbb{R}^\ell$, is *linear* if around every point x_0 there are: - an open $O \ni x_0$; - sections s_{ij} on O ($i \in I$ finite, $j \le \ell$); - weights $\sigma_i > 0$ with $\sum_i \sigma_i = 1$;

such that, for every t, the sections $\sum_j t_j s_{ij}$ with the weights σ_i form a local representation of Λ_t on O. So one domain, one set of sections and one set of weights serve all t. This is how the text's Λ_t and $\tilde\Lambda(t, w) = \Lambda_t(w)$ are formalized. The text asks that $\tilde\Lambda$ be an sc⁺-multisection of the pull-back of W to $\mathbb{R}^{\bar\ell} \times X$; a linear family gives that representation directly. At $t = 0$ every branch is the zero section, so Λ_0 is the trivial multisection.

The pointwise norm of a linear family is controlled by its sections: - the norm $N(\Lambda)(x)$ is attained at a branch value of any local representation `Chapter15/ParamFamily · SBLocalization.pointwiseNorm_le_of_isLocalRepOn`; - so if $N(s_{ij}) \le b$ then $N(\Lambda_t)(x) \le |t|_1\, b$, where $|t|_1 = \sum_j |t_j|$ `Chapter15/ParamFamily · SBLocalization.pointwiseNorm_le_of_linear`.

(15.1) at a point `Chapter15/ParamFamily · SBLocalization.IsParamOntoAt`. Let x be a level-1 point. The family satisfies (15.1) at x if it has a linear representation around x with the following property. For every operator L of the linearization $T(f, \Lambda_0)(x)$ (§XV.8), every chart presentation of the reduced tangent space $T^R_x X$, every branch i and every $w \in W_x$, there are $v \in T^R_x X$ and $\tau \in \mathbb{R}^\ell$ with

$$L v + \textstyle\sum_j \tau_j s_{ij}(x) = w.$$

The text writes (15.1) as "$T^R_{(\tilde f, \tilde\Lambda)}(0, x)$ is onto". Its local constructions phrase it as: the image of $f'(x)$ on

$T^R_x X$, together with the vectors $s_{ij}(x)$, spans W_x. Two readings are made: - $f'(x)$ is read as the operator of $T(f, \Lambda_0)(x)$, which at a zero of f is the linearization of f (§XV.24); - the t-derivative of $f - \sum_j t_j s_{ij}$ is $\tau \mapsto -\sum_j \tau_j s_{ij}(x)$, and its sign is immaterial for surjectivity.

At points with $d_X(x) = 0$, $T^R_x X = T_x X$, and (15.1) is the text's interior condition. So the interior and boundary constructions of the text become one construction.

Sums of families `Chapter15/ParamFamily · SBLocalization.famAdd`. For families Λ over $\mathbb{R}^\ell$ and Λ' over $\mathbb{R}^{\ell'}$, the sum over $\mathbb{R}^{\ell+\ell'}$ is $(\Lambda \oplus \Lambda')_{(t,t')} = \Lambda_t \oplus \Lambda'_{t'}$, the sum of multisections of Definition 13.2.9. This is the text's $\Lambda_t = \bigoplus_i \Lambda_{t_i}^{x_i}$. - *Local representations of a sum* `Chapter15/ParamFamily · SBLocalization.isLocalRepOn_famAdd`. If (s_i, σ_i) represents Λ and $(s'_{i'}, \sigma'_{i'})$ represents Λ' on O, then the sections $s_i + s'_{i'}$ with weights $\sigma_i \sigma'_{i'}$ represent the sum. The pairs (i, i') are re-enumerated as one finite index set; the weights sum to 1; the sums are sc⁺ on O. The value of the sum at w is $\sum\{\sigma_i \sigma'_{i'} : s_i(y) + s'_{i'}(y) = w\}$, which is how Definition 13.2.9 computes a sum on a common representation domain. - *Linearity* `Chapter15/ParamFamily · SBLocalization.IsLinearFamily.famAdd`. With linear representations, the branches $\sum_j t_j s_{ij} + \sum_k t'_k s'_{i'k}$ are the combinations of the concatenated sections (`paramSec_append` above). So the sum of linear families is linear, on $O \cap O'$. - *(15.1) for a sum* `Chapter15/ParamFamily · SBLocalization.IsParamOntoAt.famAdd_left` `Chapter15/ParamFamily · SBLocalization.IsParamOntoAt.famAdd_right`. (15.1) for either summand at x gives it for the sum. At $t = 0$ the sum is $\Lambda_0 \oplus \Lambda_0 = \Lambda_0$, so the operators L are the same. For a branch (i, i') of the sum, solve with the summand that has (15.1), and put $\tau = 0$ on the parameters of the other summand. - *Two inequalities the text uses silently.* - $N(\Lambda \oplus \Lambda')(x) \le N(\Lambda)(x) + N(\Lambda')(x)$ `Chapter15/ParamFamily · SBLocalization.pointwiseNorm_multisectionAdd_le`. A vector in the support of the sum is $a + b$ with $\Lambda(a) > 0$ and $\Lambda'(b) > 0$ `Chapter15/ParamFamily · SBLocalization.exists_of_multisectionAdd_pos`, and $N(a+b) \le N(a) + N(b)$ `Chapter15/ParamFamily · SBLocalization.normW_add_le`. - The domain support of a sum lies in the union of the domain supports `Chapter15/ParamFamily · SBLocalization.domSupp_multisectionAdd_subset`. Off both, each summand is trivial, and so is the sum; the domain support is a closure, and the closure of a union of two sets is the union of their closures.

Families good on a set `Chapter15/GeneralPositionExistence · SBLocalization.ScPlusGPFamily`. For a set Q, a family *good on* Q is a linear family Λ over some $\mathbb{R}^\ell$ with: - every Λ_t an sc⁺-multisection; - $N(\Lambda_t)(x) \le |t|_1 \, h(x)$ for all t and x; - domain supports in U; - (15.1) at every level-1 point of $S_f \cap Q$.

The structurable twin `Chapter15/ParamFamily · SBLocalization.GPFamily` asks every Λ_t to be structurable instead.

The operations on good families: - A family good on Q is good on every subset of Q `Chapter15/ParamFamily · SBLocalization.GPFamily.mono` `Chapter15/GeneralPositionExistence · SBLocalization.ScPlusGPFamily.mono`. - *The empty family* `Chapter15/GeneralPositionExistence · SBLocalization.ScPlusGPFamily.zero` has $\ell = 0$ and $\Lambda_t = \Lambda_0$, and is good on $\emptyset$. It is linear with one branch, the zero section of weight 1 `Chapter15/ParamFamily · SBLocalization.isLocalRepOn_zeroMultisection`. - The structurable empty family `Chapter15/ParamFamily · SBLocalization.GPFamily.zero` needs Λ_0 to be structurable. With a good system it is, with the zero decoration `Chapter15/ParamFamily · SBLocalization.isStructurable_zeroMultisection_of_goodSystem`. - *Sums* `Chapter15/GeneralPositionExistence · SBLocalization.ScPlusGPFamily.add`. Families good on Q and Q' add to a family good on $Q \cup Q'$: - the sum of sc⁺-multisections is one (Definition 13.2.9) `Chapter13/MultisectionAlgebra · SBLocalization.definition_13_2_9`; - the norm bound adds, $|t|_1 h + |t'|_1 h = |(t, t')|_1 h$; - the domain supports stay in U; - (15.1) holds on Q by `famAdd_left` and on Q' by `famAdd_right`.

The structurable sum `Chapter15/ParamFamily · SBLocalization.GPFamily.add` is the same, with Proposition 13.3.12 for the structurability of a sum `Chapter13/StructurableMultisection · SBLocalization.proposition_13_3_`

12. - By induction on a finite index set, with the empty family as the empty sum, families good on $Q_1, \dots, Q_k$ give a family good on $\bigcup_i Q_i$ Chapter15/GeneralPositionExistence · SBLocalization.nonempty_scPlusGPFamily_biUnion Chapter15/GeneralPositionAssembly · SBLocalization.nonempty_gpFamily_biUnion. - So without a good system, sums of sc⁺-families need nothing; with structurable families, the empty sum needs a good system. This is the only place where the two forms of the theorem differ.

Step (c), from local to global Chapter15/GeneralPositionExistence · SBLocalization.exists_scPlusGPFamily_of_compact Chapter15/GeneralPositionAssembly · SBLocalization.exists_gpFamily_of_compact. Suppose every $x \in S_f$ lies in an open saturated Q_x carrying a good family. In the structurable form this hypothesis is named Chapter15/GeneralPositionAssembly · SBLocalization.HasLocalGPFamilies. Then there is one family good on an open $Q \supseteq S_f$. - The sets $\pi(Q_x)$ are open in $|X|$, since π is open (Proposition 7.1.8), and they cover the compact $|S_f|$. Choose finitely many $x_1, \dots, x_k$ and put $Q = \bigcup_i Q_{x_i}$. - $S_f \subseteq Q$: a point of S_f has its orbit in some $\pi(Q_{x_i})$, and Q_{x_i} is saturated. - The family on Q is the sum of the k families.

The sc⁺ version first saturates the open neighbourhoods it is given (§XV.23). This is the text's "From local to global", with $\bar{\ell} = \ell_{x_1} + \cdots + \ell_{x_k}$.

Steps (d) and (e), the choice of t. Step (d) (§XV.25) gives $\varepsilon > 0$ and a Lebesgue-null set off which (f, Λ_t) is in general position for $\|t\| < \varepsilon$ (sup norm on $\mathbb{R}^\ell$). The hypothesis $N(\Lambda_t) \le |t|_1$ it needs follows from $N(\Lambda_t) \le |t|_1 h$ and $h \le 1$; (15.1) holds on S_f because $S_f \subseteq Q$. - Put $r = \min(\varepsilon, 1/(\ell+1)) > 0$. A ball of positive radius has positive measure, so it is not contained in a null set. Hence there is t with $\|t\| < r$ and (f, Λ_t) in general position Chapter15/GeneralPositionAssembly · SBLocalization.exists_norm_lt_of_ae. - From $\|t\| < 1/(\ell+1)$: $|t|_1 \le \ell \|t\| < 1$ Chapter15/GeneralPositionAssembly · SBLocalization.sum_abs_lt_one. - (1): $N(\Lambda_t)(x) \le |t|_1 h(x) < h(x)$, since $h(x) > 0$. - (2): the family's domain supports lie in U. - (4) is the choice of t. - (3) follows from (4) Chapter15/GeneralPositionAssembly · SBLocalization.isTransversal_of_isInGeneralPosition. A support point is a level-1 point, and an operator that is onto on the reduced tangent space $T^R_x X \subseteq T_x X$ is onto.

Readings. - The text's ε_0, "so that $N(\Lambda_t)(x) < 1$ … provided $|t| \le \varepsilon_0$", is $1/(\ell+1)$ in the sup norm. The bound actually used is $N(\Lambda_t) \le |t|_1 h$, which gives (1) with h and not only with 1. - "A set of measure zero … for t in its complement" is "for almost every t". - The text's remark that the complement "contains points arbitrarily close to 0" is the positive measure of balls.

Departures from the text's assembly. - The text starts from "a large parameter space $\mathbb{R}^h$, i.e. $h >> 0$". In the formalization the number of parameters is whatever the construction produces, the sum $\ell_{x_1} + \cdots + \ell_{x_k}$ of the local ones. - The text views $\tilde{\Lambda}$ as an sc⁺-multisection over $\mathbb{R}^{\bar{\ell}} \times X$ and $\tilde{f}(t,x) = (t, f(x))$ as an sc-Fredholm section there. The formalization never forms this pair on the product ep-groupoid. Everything it needs from $\tilde{\Lambda}$ is in the linear representations: (15.1) at the points of S_f, the norm bound, and the domain supports. The product appears only branch by branch, on $\mathbb{R}^\ell \times O$ with O open in the object M-polyfold (§XV.25), where Part I applies.

The assembly with the two analytic steps as hypotheses Chapter15/GeneralPositionAssembly · SBLocalization.theorem_15_3_7_hyp. Steps (c) and (e) for structurable families, as one statement. Its hypotheses: - a good system; - compact $|S_f|$; - (N, U) controlling compactness; - $0 < h \le 1$; - the local families of step (b) Chapter15/GeneralPositionAssembly · SBLocalization.HasLocalGPFamilies; - the parametric general position of step (d) Chapter15/GeneralPositionAssembly · SBLocalization.HasParametricGeneralPosition. This is stated for every linear family of sc⁺-multisections with $N(\Lambda_t) \le |t|_1$, domain supports in U and (15.1) on S_f.

Its conclusion is a structurable Λ with (1)–(4). The structurable form of the theorem then follows from a good system and the two steps Chapter15/GeneralPositionAssembly · SBLocalization.theorem_15_3_7_of_hyp. Both

steps are proved from the theorem's hypotheses in §§XV.23–XV.25, so these statements are the skeleton of the final proof, not additional assumptions of it.

XV.23 Proof of Theorem 15.3.7, II: the local constructions

The text's "Local constructions at $x \in S_f$": - choose vectors $w_1, \dots, w_\ell \in W_x$ completing the image of $f'(x)$, on $T^R_x X$ at boundary points; - extend them to sc⁺-sections s^1_j supported in an invariant $V(x)$ with closure in $U(x)$; - symmetrize over G_x; - take the atomic multisection; - invoke the implicit function theorem for a neighbourhood $Q(x)$ on which the parametrized problem stays onto.

The formalization follows this order. It needs one more tool, the transport of (15.1) along morphisms, because the symmetrized branches are moved by the isotropy group, and because the text passes to saturations "by equivariance".

(15.1) with given vectors `Chapter15/ParamOntoTransport · SBLocalization.IsParamOntoVec`. At a level-1 point x and for vectors $v_1, \dots, v_\ell \in W_x$: for every operator L of $T(f, \Lambda_0)(x)$, every chart presentation of $T^R_x X$ and every $w \in W_x$, there are $u \in T^R_x X$ and τ with $Lu + \sum_j \tau_j v_j = w$. (15.1) for a family at x is this property for the values $s_{ij}(x)$ of every branch of a linear representation `Chapter15/ParamOntoTransport · SBLocalization.isParamOntoAt_iff_vec`.

Transport along morphisms `Chapter15/ParamOntoTransport · SBLocalization.IsParamOntoVec.of_mor`. If $\varphi : x \to y$ and (15.1) holds at x with v_j, it holds at y with $\mu(\varphi, v_j)$.

Proof. 1. *The operators at y.* Every operator L' of $T(f, \Lambda_0)(y)$ is the conjugate $\mu(\varphi, \cdot) \circ L \circ (T\varphi)^{-1}$ of an operator L of $T(f, \Lambda_0)(x)$. This is the functor property of the linearization (§XV.9) `Chapter15/LinearizationFunctor · SBLocalization.theorem_15_1_1_functor`, read on the support of the pushed-forward formal sum. 2. *The reduced tangent space at y.* Take a chart at x, restricted to the sheet of φ, and transport it along φ. Then $T\varphi$ maps $T^R_x X$ into the reduced tangent space at y computed in the transported chart `Chapter15/ParamOntoTransport · SBLocalization.tangentMorCLE_mem_reducedTangentFiber_transport`. By chart independence of T^R (Part I) `Chapter2/ReducedTangentIntrinsic · MPolyfold.reducedTangentFiber_eq`, this is the reduced tangent space of every chart presentation at y. 3. *Solving.* $\mu(\varphi, \cdot) : W_x \to W_y$ is a linear bijection with inverse $\mu(\varphi^{-1}, \cdot)$ `Chapter15/ParamOntoTransport · SBLocalization.muLin_surjective`. Write $w = \mu(\varphi, w_0)$ and solve $Lu + \sum_j \tau_j v_j = w_0$ at x. Then $T\varphi\, u \in T^R_y X$ and

$$L'(T\varphi\, u) + \textstyle\sum_j \tau_j \mu(\varphi, v_j) = \mu(\varphi, Lu + \sum_j \tau_j v_j) = w.$$

Linear representations are carried too `Chapter15/ParamOntoTransport · SBLocalization.exists_linearRep_of_mor`. Suppose Λ_t is a functor for every t and $(\sum_j t_j s_{ij}, \sigma_i)$ represents it on $O \ni x$. Transport each section along the local diffeomorphism of φ; this gives sections on a neighbourhood of y `Chapter15/ParamOntoTransport · SBLocalization.transSec_eq_muLin`. Since μ is fibrewise linear, the transported combinations are the combinations of the transported sections `Chapter15/ParamOntoTransport · SBLocalization.paramSec_transSec_eqOn`. They represent Λ_t there because Λ_t is a functor. So (15.1) for a family passes along morphisms in both directions `Chapter15/ParamOntoTransport · SBLocalization.IsParamOntoAt.of_mor` `Chapter15/ParamOntoTransport · SBLocalization.IsParamOntoAt.of_mor_inv`.

Saturation ("the same assertion also holds for points … in the saturation of $Q(x)$"). - S_f is saturated: if $\varphi : a \to z$ and $f(a) = 0$, then $f(z) = \mu(\varphi, 0) = 0$ `Chapter15/LocalFamilies · SBLocalization.mem_solutionSet_tgt`. - A family good on an open V is good on the saturation of V `Chapter15/LocalFamilies · SBLocalization.`

GPFamily.saturate Chapter15/GeneralPositionExistence · SBLocalization.ScPlusGPFamily.saturate. For $z \in S_f$ in the saturation there are $a \in V$ and $\varphi : a \to z$. Then $a \in S_f$, so (15.1) holds at a and passes to z along φ. - The saturation of an open set is open, because π is open. So it suffices to produce, at each $x \in S_f$, an open $V \ni x$ carrying a good family Chapter15/LocalFamilies · SBLocalization.hasLocalGPFamilies_of_nhds.

Seed data Chapter15/LocalFamilies · SBLocalization.SeedData. Seed data consist of: - a point x; - a natural representation of G_x on an open $U(x)$ with the properness property; - an open $V(x) \ni x$ invariant under the action, with $\operatorname{cl} V(x) \subseteq U(x)$; - sc⁺-sections $s_1, \dots, s_\ell$ of W supported in $V(x)$.

Such $U(x)$, $V(x)$ exist inside any open neighbourhood of x Chapter13/AtomicMultisection · SBLocalization.exists_atomicNbhd (Theorem 7.1.13 and the proof of Theorem 7.5.7).

The atomic family Chapter15/LocalFamilies · SBLocalization.SeedData.Λ. For each t, Λ_t is Part XIII's atomic multisection generated by the seed $\sum_j t_j s_j$. Its branches on $U(x)$ are the translates

$$(\textstyle\sum_j t_j s_j)^g(y) = \mu(\Gamma(g, g^{-1} * y), \sum_j t_j s_j(g^{-1} * y)), \qquad g \in G_x,$$

which is the text's $s_t^{x,g}$. Each Λ_t is an sc⁺-multisection. - *Linear branches on $U(x)$* Chapter15/LocalFamilies · SBLocalization.SeedData.isLocalRepOn_branch. Since μ is linear on fibres, $(\sum_j t_j s_j)^g = \sum_j t_j s_j^g$ Chapter15/LocalFamilies · SBLocalization.natTerm_paramSec. So on $U(x)$ the family has the linear representation with sections s_j^g and weights $1/|G_x|$. - *Away from the seed* Chapter15/LocalFamilies · SBLocalization.SeedData.isLocalRepOn_zero. Off the saturation of $\operatorname{cl} V(x)$, Λ_t is the trivial multisection, represented by the zero section. - *Linear everywhere* Chapter15/LocalFamilies · SBLocalization.SeedData.isLinearFamily. There are two cases for a point x_0. - If x_0 is the target of a morphism φ from a point of $U(x)$, the representation on $U(x)$ is carried along φ (`exists_linearRep_of_mor`). - Otherwise x_0 lies off the closed saturation of $\operatorname{cl} V(x)$, and the zero representation serves. - *Structurable* Chapter15/LocalFamilies · SBLocalization.SeedData.isStructurable_Λ. Given a good system, every Λ_t is structurable: an atomic multisection is structurable (Theorem 13.5.3) Chapter13/AtomicStructurable · SBLocalization.theorem_13_5_3_of_goodSystem. This is the text's "for fixed t it is structurable". - *Domain support* Chapter15/LocalFamilies · SBLocalization.SeedData.domSupp_Λ_subset. It lies in the saturation of $U(x)$. - *Norm* Chapter15/LocalFamilies · SBLocalization.SeedData.norm_le. If $N(s_j) \le c$ and $c \le h$ on the saturation of $U(x)$, then $N(\Lambda_t) \le |t|_1 h$. - At a point reached from $U(x)$, every branch value is $\mu(\Gamma, \sum_j t_j s_j(\cdot))$. Its norm is at most $|t|_1 c$, since N is invariant under μ Chapter13/AtomicConstruction · SBLocalization.SymmetricFamily.ofSeed_normW_le Chapter13/AtomicConstruction · SBLocalization.AtomicData.pointwiseNorm_mult_le. And $c \le h$ there. - At other points the pointwise norm is 0. - *(15.1)* Chapter15/LocalFamilies · SBLocalization.SeedData.isParamOntoAt. Let $W \ni x$ be open such that the vectors $s_j(y)$ satisfy (15.1) at every point y of $S_f \cap W$. Put

$$Q_0 = \bigcap_{g \in G_x} (U(x) \cap \Phi_g^{-1}(W)).$$

This set is open (a finite intersection) and contains x. At $y \in Q_0 \cap S_f$, the branch g takes the values $\mu(m, s_j(\operatorname{src} m))$, where $m = \Gamma(g, \Phi_{g^{-1}}(y))$ is a morphism from $\Phi_{g^{-1}}(y) \in W$ to y. Its source lies in S_f, since S_f is saturated, and in W. So (15.1) holds there with s_j, and `IsParamOntoVec.of_mor` carries it to y for the branch g. This is the text's "the linearization … at $(0, x)$ is also surjective for every g", extended from x to the points of S_f near x. - *Together* Chapter15/LocalFamilies · SBLocalization.SeedData.gpFamily Chapter15/GeneralPositionExistence · SBLocalization.SeedData.scPlusGPFamily. The atomic family is good on Q_0: structurable given a good system, and sc⁺ without one.

Local families from local seeds Chapter15/LocalFamilies · SBLocalization.hasLocalGPFamilies_of_seeds Chap-

ter15/GeneralPositionExistence · SBLocalization.exists_scPlusGPFamily_nhds. The analytic input is named *local seeds* Chapter15/LocalFamilies · SBLocalization.HasLocalParamSeeds. It says: at every $x \in S_f$, for every open $O \ni x$ and every $\varepsilon > 0$, there are - finitely many sc⁺-sections s_j supported in O with $N(s_j) \le \varepsilon$, and - an open $W \ni x$ such that the $s_j(y)$ satisfy (15.1) at every level-1 point y of $S_f \cap W$.

Given local seeds, every $x \in S_f$ has an open neighbourhood carrying a good family.

Proof. 1. Put $c = h(x)/2 > 0$ and $W_1 = U \cap \{y : h(y) > c\}$, an open neighbourhood of x. 2. Choose $U(x) \subseteq W_1$ and $V(x)$ as above, and seeds with $O = V(x)$ and $\varepsilon = c$. 3. $c \le h$ *on the saturation of* $U(x)$. A point y there is isomorphic to some $a \in U(x)$, and $h(y) = h(a) > c$ because h is constant along morphisms. 4. *The saturation of* $U(x)$ *lies in* U, because U is saturated. 5. So the atomic family has $N(\Lambda_t) \le |t|_1 h$, domain support in U, and (15.1) on Q_0.

The text asks $N(s_j^1(y)) \le \min\{1, h(y)\}$ on $U(x)$. The formalization takes the constant bound $h(x)/2$ and shrinks $U(x)$ so that $h > h(x)/2$ on it. This gives the bound on the saturation directly.

With local seeds, the structurable form is proved in one statement Chapter15/LocalFamilies · SBLocalization.theorem_15_3_7_hyp_seeds Chapter15/LocalFamilies · SBLocalization.theorem_15_3_7_of_seeds. These are intermediate steps of the final proof.

Seeds from two facts at single points Chapter15/LocalSeeds · SBLocalization.hasLocalParamSeeds_of. Local seeds follow from bump functions, the smoothness of the points of S_f, and two facts: - *small vectors* Chapter15/LocalSeeds · SBLocalization.HasPointwiseParamOnto: at every level-1 point $x \in S_f$ and for every $\varepsilon > 0$, there are smooth vectors $w_j \in W_x$ with $N(w_j) < \varepsilon$ satisfying (15.1) at x; - *openness* Chapter15/LocalSeeds · SBLocalization.HasParamOntoOpen: if the values of sc⁺-sections s_j satisfy (15.1) at $x \in S_f$, there is an open $W \ni x$ such that they satisfy it at every level-1 point of $S_f \cap W$.

Proof. 1. At $x \in S_f$, take the small vectors with $N(w_j) < \varepsilon/2$. 2. Part I's Lemma 5.3.3, on the object M-polyfold with its bump functions (Theorem 12.3.2 (1)), extends each smooth w_j to an sc⁺-section s_j with $s_j(x) = w_j$, support in O, and $N(s_j) \le \varepsilon$ Chapter5/BumpFunctions · lemma_5_3_3. 3. Then (15.1) holds at x with the $s_j(x)$, and openness gives W.

Points of S_f are smooth by the regularity that the tame germ data provide Chapter15/Transversality · SBLocalization.mem_smoothSet_of_eq. The structurable form from the two facts and parametric general position Chapter15/LocalSeeds · SBLocalization.theorem_15_3_7_of_pointwise is the next intermediate step.

The two facts are the text's choice of the w_j ("we can pick the w_i as small as we wish") and its appeal to the implicit function theorem for $Q(x)$. Both are proved from the theorem's hypotheses in §XV.24.

Departures from the text's local constructions. - The text's two cases, $d_X(x) = 0$ and $d_X(x) \ge 1$, are one construction, because (15.1) is stated on $T_x^R X$. - The text's "(Interior)" and "(Boundary)" conclusions assert that the parametrized solution set over $\{|t| < \varepsilon_x\} \times Q(x)$ is a tame branched ep⁺-subgroupoid. The formalization does not use this structure: what the assembly needs from $Q(x)$ is (15.1) at the points of $S_f \cap Q(x)$. The local structure of the parametrized solution set enters only in §XV.25, branch by branch, through Part I.

XV.24 Proof of Theorem 15.3.7, III: (15.1) and Part I's conditions (i)–(ii)

The two facts of §XV.23 concern (15.1), stated on the ep-groupoid with reduced tangent spaces. Part I's proof of Theorem 5.3.10 works with conditions (i)–(ii) for a parametrized section in an M-polyfold chart,

with the full tangent space. This subsection proves the two conditions equivalent at a zero of f, and then derives both facts from Part I.

Part I's conditions Chapter5/GeneralPosition · StrongBundleChart.IsParamGP. Take a strong bundle chart centred at y (chart point 0, retraction r, model fibre K_0) and a presentation T of its partial quadrant, whose minimal subspace E_0 is the chart's reduced tangent space. Let $F(a,u) = \mathrm{Lin}_g(0)u + \sum_i a_i \hat{t}_i(0)$ be the linearization of $g + \sum_i \lambda_i t_i$ at $(0,y)$. The conditions are: - (i) F maps $\mathbb{R}^m \times T_0O$ onto K_0; - (ii) the kernel of F is transversal to $\mathbb{R}^m \oplus T^R$: every $w \in T_0O$ is $u + e$ with $e \in E_0$ and $F(a,u) = 0$ for some a.

The bridge (extra) Chapter15/ParamOntoBridge · SBLocalization.isParamOntoVec_iff_isParamGP. Let x be a level-1 zero of f, let a strong bundle chart of W be centred at x with a presentation T, and let s_j be sc⁺-sections. Then (15.1) at x with the vectors $s_j(x)$ holds if and only if Part I's (i)–(ii) hold in that chart for $f + \sum_j t_j s_j$.

Proof. Both sides are read in the chart. 1. *The operator.* At a zero of f, the only operator of $T(f,\Lambda_0)(x)$ is the intrinsic form of the chart linearization $D((\hat{f} - \hat{0}) \circ r)(0)$ Chapter15/ParamOntoBridge · SBLocalization.mem_support_linearization_zero_iff Chapter15/ParamOntoBridge · SBLocalization.linAt_principal_eq_subDeriv. It is taken at the chart point of x, which is 0 Chapter15/ParamOntoBridge · SBLocalization.levelLift_eq_zero_of_centred. 2. *(15.1) in the chart* Chapter15/ParamOntoBridge · SBLocalization.onto_chart_iff. (15.1) says that $(v,\tau) \mapsto D((\hat{f} - \hat{0}) \circ r)(0)v + \sum_j \tau_j \hat{s}_j(0)$ maps $(T_0O \cap E_0) \times \mathbb{R}^\ell$ onto K_0. The fibre W_x is K_0 read through the chart, and $T^R_x X$ is $T_0O \cap E_0$. 3. *(i)–(ii) are equivalent to this reading* Chapter15/ParamOntoBridge · SBLocalization.isParamGP_iff_onto_chart. Write L for the chart linearization and $\hat{s}_j$ for $\hat{s}_j(0)$. - *Forward.* Given $k \in K_0$, (i) gives (a,u) with $Lu + \sum a_j \hat{s}_j = k$. Then (ii), applied to u, gives (a',u') with $Lu' + \sum a'_j \hat{s}_j = 0$ and $u - u' \in E_0$. So $(a - a', u - u')$ hits k with $u - u'$ reduced. - *Backward.* (i) is immediate. For (ii), take $w \in T_0O$. Then $Lw \in K_0$; solve $Lu + \sum \tau_j \hat{s}_j = Lw$ with u reduced. The pair $(-\tau, w - u)$ is in the kernel, and $w - (w - u) = u \in E_0$. 4. *Every chart presentation.* (15.1) quantifies over all chart presentations, while the right side uses one. The two agree because the reduced tangent space does not depend on the chart (Part I) Chapter2/ReducedTangentIntrinsic · MPolyfold.reducedTangentFiber_eq.

Extra: the text states (15.1) with $T^R_x X$, while Part I's proof of Theorem 5.3.10 uses (i)–(ii) with the full tangent space. The text presumably takes their equivalence for granted when it cites "the corresponding implicit function theorem".

Tame strong bundle charts centred at a point of S_f, with a presentation, exist by the tame germ data Chapter15/GeneralPositionGoodSystem · SBLocalization.exists_tameChart_centred.

Small vectors (explicit) Chapter15/GeneralPositionGoodSystem · SBLocalization.hasPointwiseParamOnto. With bump functions and the tame germ data, the small-vectors fact of §XV.23 holds.

Proof. Let $x \in S_f$ be a level-1 point and $\varepsilon > 0$. 1. Take a tame chart centred at x. 2. Part I's proof of Theorem 5.3.10 provides sc⁺-sections s_j of the object M-polyfold bundle for which $f + \sum_j t_j s_j$ satisfies (i)–(ii) in this chart. They can be chosen with norm at most 1 for any given auxiliary norm Chapter5/GeneralPosition · exists_sections_isParamGP. 3. Apply this to the auxiliary norm $(2/\varepsilon)N$; a positive multiple of an auxiliary norm is one. This gives $N(s_j) \le \varepsilon/2 < \varepsilon$. 4. The bridge turns (i)–(ii) into (15.1) for the vectors $w_j = s_j(x)$. 5. The w_j are smooth, because x is smooth and sc⁺-sections map smooth points to smooth vectors.

Explicit: this is the text's choice of $w_1, \dots, w_\ell$ "as small as we wish", made in a chart.

Openness (explicit) Chapter15/GeneralPositionGoodSystem · SBLocalization.hasParamOntoOpen. For tame X and f with tame germ data, the openness fact of §XV.23 holds.

Proof. Let sc⁺-sections s_j satisfy (15.1) at $x \in S_f$. 1. The bridge, in a tame chart centred at x, gives (i)–(ii). 2. Part I turns (i)–(ii) into general position of $F(t,y) = f(y) + \sum_j t_j s_j(y)$ on $\mathbb{R}^\ell \times X$ at $(0,x)$ `Chapter5/GeneralPosition · isGeneralPositionGerm_paramSection_of_isParamGP`. 3. $\mathbb{R}^\ell \times X$ is tame `Chapter3/ParamPerturbation · prod_rn_isTame` and F is a tame sc-Fredholm section `Chapter3/ParamPerturbationG · theorem_3_1_21_tame`. So general position at a zero spreads to the zeros in an open $W_0 \ni (0,x)$ `Chapter5/GeneralPosition · exists_isOpen_isGeneralPositionGerm`. 4. Put $W = \{y : (0,y) \in W_0\}$. At a point $y \in S_f \cap W$, $(0,y)$ is a zero of F in general position. 5. In a tame chart centred at y, Part I recovers (i)–(ii) `Chapter5/GeneralPosition · isParamGP_of_isGeneralPositionGerm`, and the bridge at y gives (15.1) there.

Explicit: this is the text's "from the local implicit function theorem we deduce", made precise as the openness of Part I's general position.

Both facts are needed only at points of S_f, which are smooth, so centred tame charts are available.

XV.25 Proof of Theorem 15.3.7, IV: achieving global transversality

Parametric general position (explicit) `Chapter15/ParametricGeneralPosition · SBLocalization.hasParametricGeneralPosition`. Suppose X is tame, f is an sc-Fredholm section functor with tame germ data, $|S_f|$ is compact, and (N,U) controls compactness. Let $t \mapsto \Lambda_t$, $t \in \mathbb{R}^\ell$, be a family of sc⁺-multisections with: - $N(\Lambda_t) \le |t|_1$; - domain supports in U; - (15.1) at every level-1 point of S_f.

Then there is $\varepsilon > 0$ such that (f, Λ_t) is in general position for almost every t with $\|t\| < \varepsilon$. This is step (d) of §XV.22. The proof does not use that the family is linear everywhere (the linear representations inside (15.1) at the points of S_f suffice), nor bump functions, nor h.

The text proves this in "Achieving global transversality": - it uses Theorem 15.2.5 for an ε below which the parametrized solution set is a tame branched ep⁺-subgroupoid with surjective reduced linearizations; - around each of its points (t_0, x_0) it writes the branches as manifolds with corners M_i; - it applies Sard's theorem to $F \cap M_i \to \mathbb{R}^{\bar\ell}$ for every intersection F of local faces; - it covers the set (15.3) by countably many, or by compactness finitely many, such neighbourhoods.

The formalization keeps the plan but makes three changes. - It centres the local neighbourhoods only at points $(0,x)$ with $x \in S_f$. The form of (15.2) proved below shows that for small t the support of $\Lambda_t \circ f$ stays near S_f. - It works branch by branch, where each branch is a section of a strong bundle over an open subset of the object M-polyfold, so that Part I's results apply directly. - Part I's Theorem 4.3.1 in local form carries the faces. This replaces the text's "obvious branched ep⁺-groupoid version of Theorem 4.3.1".

(i) Part I's Sard step, locally (extra) `Chapter15/LocalSlice · StrongBundle.exists_null_isGeneralPositionGerm_paramSlice_near`. Let X be a tame M-polyfold, g a tame sc-Fredholm section, and $t_1, \dots, t_m$ sc⁺-sections. Suppose $F(\lambda, y) = g(y) + \sum_i \lambda_i t_i(y)$ is in general position at a zero z_0. Then there are an open $W \ni z_0$ in $\mathbb{R}^m \times X$ and a null set $C \subseteq \mathbb{R}^m$ such that, for $\lambda \notin C$, the slice $F(\lambda, \cdot)$ is in general position at its zeros y with $(\lambda, y) \in W$.

Proof. 1. F is a tame sc-Fredholm section on the tame $\mathbb{R}^m \times X$ `Chapter3/ParamPerturbationG · theorem_3_1_21_tame Chapter3/ParamPerturbation · prod_rn_isTame`. 2. General position at z_0 gives an open W_0 on which the zero set A of F is in general position `Chapter5/GeneralPosition · exists_isOpen_isGeneralPositionGerm`. 3. *Faces.* Part I's Theorem 4.3.1 in local form gives a null set C_1 off which the fibres $\{y : (\lambda, y) \in A\}$ are submanifolds in general position to the faces `Chapter4/Families · exists_local_family`. 4. *Surjectivity.*

Part I's Sard step gives a null set C_2 off which the linearizations of the slice are onto at its zeros near z_0 Chapter5/Transversality · exists_null_isLinSurjAt_paramSlice_near. 5. *Assembling general position of the slice.* - The slice is a tame sc-Fredholm section Chapter3/TameGermsAddG · theorem_3_1_18_tame. - Near a zero, its zero set is the fibre piece of A, a submanifold Chapter15/LocalSlice · MPolyfold.IsGeneralPositionAt.exists_inter. - Part I's characterization of general position by good position of a tame germ applies Chapter5/GeneralPosition · isGoodPositionGermTame_of_isGeneralPositionAt. - So the slice is in general position at every zero in W, with $C = C_1 \cup C_2$.

Extra: Part I's Theorem 5.3.10 is stated globally, under compactness Chapter5/GeneralPosition · theorem_5_3_10_of_family. The proof of Theorem 15.3.7 needs its Sard step near one point.

(ii) A branch as a Part I section. Let $(\sum_j t_j s_{ij}, \sigma_i)$ be a linear representation of the family on O, and fix a branch i. - *The parametrized section.* On the open subset O of the object M-polyfold (tame, since an open subset of a tame M-polyfold is tame), take $g = (f-0)|_O$, the section of $W|_O$ of §XV.10, and $t_j = (-s_{ij})|_O$ Chapter15/BranchChart · SBLocalization.negRestrict. - *Its slices are the branches* Chapter15/BranchChart · SBLocalization.paramSlice_branch_eq. The slice at t of $g + \sum_j t_j(-s_{ij})|_O$ is $(f - \sum_j t_j s_{ij})|_O$. Its zeros are the points where f meets branch i of Λ_t. - *(15.1) gives Part I's (i)–(ii)* Chapter15/BranchChart · SBLocalization.isParamGP_restrictTo_of_onto. Take a chart of W centred at x with domain in O, transported to $W|_O$. The chart operator of g is the chart linearization of f Chapter15/BranchChart · SBLocalization.principal_eq_fiberLin, and the principal part of $(-s)|_O$ is $-\hat{s}$ Chapter15/BranchChart · SBLocalization.principal_restrictTo_negRestrict. - For (i): solve with (15.1) and change the sign of τ. - For (ii): for w, solve $Lv + \sum_j \tau_j \hat{s}_{ij} = Lw$ with v reduced. Then $(\tau, w - v)$ is in the kernel and $w - (w - v) = v \in E_0$.

This is the argument of the bridge (§XV.24), in the form needed here. - *General position at* $(0, y)$ Chapter15/ParametricGeneralPosition · SBLocalization.isGeneralPositionGerm_branchParam. Suppose (15.1) holds at $y \in S_f \cap O$. 1. y is smooth Chapter15/Transversality · SBLocalization.mem_smoothSet_of_eq. 2. The tame germ data give a tame chart centred at y, restricted into O. 3. The operator of $T(f, \Lambda_0)(y)$ is obtained from a local linearization datum of Λ_0. 4. Then (15.1) gives (i)–(ii) for the branch, and Part I gives general position of the parametrized branch at $(0, y)$ Chapter5/GeneralPosition · isGeneralPositionGerm_paramSection_of_isParamGP.

The s_{ij} are sc$^+$ on O, as the branches of Λ_{e_j} Chapter15/ParametricGeneralPosition · SBLocalization.isScPlusSectionOn_of_paramSec.

(iii) Local general position Chapter15/ParametricGeneralPosition · SBLocalization.exists_local_paramGP. Suppose X is tame, f has tame germ data, the Λ_t are sc$^+$, $x_0 \in S_f$ is a level-1 point, and (15.1) holds at x_0. Then there are an open $V \ni x_0$, a $\delta > 0$ and a null set C such that (f, Λ_t) is in general position at every $y \in V$ with $\Lambda_t(f(y)) > 0$, whenever $\|t\| < \delta$ and $t \notin C$.

Proof. 1. Take the linear representation on $O \ni x_0$ from (15.1). 2. For each branch i, (ii) and (i), applied on $\mathbb{R}^\ell \times O$, give an open $W_i \ni (0, x_0)$ and a null set C_i. 3. Shrink each W_i to a product $u_i \times v_i$. Take δ with the δ-ball inside every u_i, put $v' = \bigcap_i v_i$, let V be its image in X, and put $C = \bigcup_i C_i$. 4. *General position at the support points in* V. Let $y \in V$ with $\Lambda_t(f(y)) > 0$. The operators of $T(f, \Lambda_t)(y)$ are the linearizations at y of $f - \sum_j t_j s_{ij}$ over the branches through $f(y)$ (Definition 15.1.7, §XV.8). For each such branch, y is a zero of the slice at t, so the slice is in general position at y. 5. In a chart at y restricted to O, this gives the reduced surjectivity of that operator (§XV.16) Chapter15/GeneralPositionLocal · SBLocalization.isReducedOntoAtLevel_of_isGeneralPositionGerm. Hence general position at y in the sense of Definition 15.3.5 at one point Chapter15/GeneralPositionLocal · SBLocalization.IsInGeneralPositionAt.

(iv) Invariance under morphisms (extra) Chapter15/ParametricGeneralPosition · SBLocalization.

isInGeneralPositionAt_of_mor. General position at a point passes along morphisms: if $\varphi : y \to x$ and (f, Λ) is in general position at y, it is so at x. The proof is that of the transport of (15.1) in §XV.23 without the parameters Chapter15/ParametricGeneralPosition · SBLocalization.isReducedOntoAtLevel_of_mor: - the operators at x are conjugates of those at y (§XV.9); - $T\varphi$ maps reduced tangent vectors to reduced tangent vectors; - $\mu(\varphi, \cdot)$ is onto.

Extra: the text uses this silently when it passes to saturations "by equivariance" ("the properties of $(\tilde{f}, \tilde{\Lambda})$ at $(0, x')$ are the same as those of $(0, x)$").

(v) The form of (15.2) the proof uses (extra) Chapter15/ParametricGeneralPosition · SBLocalization.exists_pos_auxLe_subset. Suppose f is an sc-Fredholm section functor, (N, U) controls compactness, and $V \supseteq S_f$ is open and saturated. Then there is $\varepsilon > 0$ with $\{x \in U : N(f(x)) \le \varepsilon\} \subseteq V$.

Proof. By contradiction. 1. Suppose that for every n there is $x_n \in U \setminus V$ with $N(f(x_n)) \le 1/(n+1)$. The orbits $\pi(x_n)$ lie in the compact closure that (N, U) provides, so they have a cluster point $q = \pi(z)$. 2. The object space is metrizable, so z has a decreasing neighbourhood basis B_k. Since π is open and q is a cluster point, there are $n_k \ge k$ and $y_k \in B_k$ with $\pi(y_k) = \pi(x_{n_k})$. 3. Because U and V are saturated, $y_k \in U \setminus V$. 4. $N(f(y_k)) \le 1/(k+1)$, since $N \circ f$ is invariant along morphisms: $f(\mathrm{tgt}\,\varphi) = \mu(\varphi, f(\mathrm{src}\,\varphi))$, and N is invariant under μ. 5. So $y_k \to z$ and $N(f(y_k)) \to 0$. The third property of an auxiliary norm (Part I's Definition 5.1.1 (3)) gives $f(y_k) \to 0_z$. 6. Since f is continuous, $f(z) = 0$. Then $z \in S_f \subseteq V$, and V is open, so $y_k \in V$ for large k, a contradiction.

On the support of $\Lambda \circ f$, $N(f(x)) \le N(\Lambda)(x)$, and $x \in U$ once the domain support lies in U Chapter15/ParametricGeneralPosition · SBLocalization.auxLe_of_pos. This is the argument of step 4 of the "in particular" (§XV.21).

Extra in this form: the text states (15.2) as the compactness of $\{(t, x) : |t| \le \varepsilon_0, \Lambda_t(f(x)) > 0\}$. It uses that compactness to keep the parametrized solution set within finitely many local neighbourhoods. The formalization proves exactly that consequence.

Proof of parametric general position. 1. *Local neighbourhoods.* Every $z \in S_f$ is smooth, hence a level-1 point, and (15.1) holds there. So (iii) gives V_z, δ_z, C_z. 2. *Finite cover.* The open sets $\pi(V_z)$ cover the compact $|S_f|$. Choose a finite set T of such z, and let V be the saturation of $\bigcup_{z \in T} V_z$. It is open, saturated, and contains S_f. 3. *Staying near S_f.* (v) gives ε_0 for this V. Choose $\varepsilon > 0$ so that $\|t\| < \varepsilon$ implies $\|t\| < \delta_z$ for $z \in T$ and $|t|_1 \le \varepsilon_0$ (recall $|t|_1 \le \ell \|t\|$). 4. *The null set* is $C = \bigcup_{z \in T} C_z$, a finite union. 5. *General position.* Let $\|t\| < \varepsilon$ and $t \notin C$. General position is checked point by point Chapter15/GeneralPositionLocal · SBLocalization.isInGeneralPosition_iff_forall_at. Let $\Lambda_t(f(x)) > 0$. - By auxLe_of_pos with $N(\Lambda_t) \le |t|_1 \le \varepsilon_0$, $x \in U$ and $N(f(x)) \le \varepsilon_0$, so $x \in V$. - So there are $z \in T$, $y \in V_z$ and $\varphi : y \to x$. - $\Lambda_t(f(y)) = \Lambda_t(f(x)) > 0$, because f and Λ_t are functors. - So (iii) gives general position at y, and (iv) carries it to x.

Explicit: this is the step "Achieving global transversality", with four readings: - Sard "on the intersections of faces" is read as Part I's local Theorem 4.3.1 with its Sard step, branch by branch on $\mathbb{R}^\ell \times O$; - the passage to saturations is (iv); - "using the compactness … a finite number of sets … suffices" is the finite cover of $|S_f|$ together with (v); - the text's appeal to Theorem 15.2.5 for the structure of the parametrized solution set is replaced by Part I's results, through (ii) and (i).

With parametric general position, the structurable form follows from the local families alone Chapter15/ParametricGeneralPosition · SBLocalization.theorem_15_3_7_hyp_local Chapter15/ParametricGeneralPosition · SBLocalization.theorem_15_3_7_of_local. These are intermediate steps of the

final proof.

XV.26 Theorem 15.3.7 with the text's hypotheses, the structurable addendum, and Remark 15.3.8

Theorem 15.3.7, (1)–(4) (explicit) `Chapter15/GeneralPositionExistence · SBLocalization.theorem_15_3_7_existence`. Under the hypotheses of §XV.21 there is an sc⁺-multisection Λ with (1)–(4).

Proof, as the Lean proof goes. 1. N is an auxiliary norm, being part of "(N, U) controls compactness". 2. *Local seeds* (§XV.23) come from: - the bump functions; - the smoothness of the points of S_f; - the small-vectors fact (§XV.24); - the openness fact (§XV.24). 3. *Local families* (§XV.23). Each $x \in S_f$ has an open neighbourhood carrying a family of sc⁺-multisections good for (N, U, h). This uses the continuity of h, its invariance along morphisms, and $h > 0$. 4. *One family* on a neighbourhood Q of S_f, by saturation and the compactness of $|S_f|$ (§§XV.22–XV.23). 5. *Parametric general position* for this family (§XV.25), with the bound $N(\Lambda_t) \le |t|_1 h \le |t|_1$ (from $h \le 1$), domain supports in U, and (15.1) on $S_f \subseteq Q$. This gives ε. 6. *The choice of* t with $\|t\| < \min(\varepsilon, 1/(\ell+1))$ (§XV.22). $\Lambda = \Lambda_t$ has (1)–(4).

Explicit: the hypotheses are the text's, plus the tame germ data inherited from §15.2. - The tame germ data are used for the smoothness of the points of S_f, the tame charts of the bridge, and the branches as Part I sections. - Tameness of X is used in the openness fact and in the local Sard step. - Bump functions are used for the seeds. - No good system and no paracompactness of $|X|$ are used.

The structurable addendum (narrower) `Chapter15/GeneralPositionGoodSystem · SBLocalization.theorem_15_3_7_of_goodSystem`. If X has a good system, the structurable form of §XV.21 holds. The proof has the same five steps, with structurable families (§XV.22): the atomic families are structurable by Theorem 13.5.3, sums by Proposition 13.3.12, and the empty family with the good system. The last step is the intermediate statement from the two facts at single points (§XV.23). For paracompact $|X|$, Theorem 13.1.8 gives a good system `Chapter13/GoodSystemExistence · EpGroupoid.theorem_13_1_8`, so the structurable form holds `Chapter15/GeneralPositionGoodSystem · SBLocalization.theorem_15_3_7_of_paracompact`.

Narrower: the good system is not in the text's hypotheses. It is necessary for this part, since a structurable multisection (Definition 13.3.6) carries a good system, so the conclusion implies the hypothesis. The text's proof opens with "We shall construct a structurable perturbation", and the step "for fixed t it is structurable" is Theorem 13.5.3, which in the formalization needs a good system (Part XIII). The text presumably has in mind the paracompact situation that Remark 15.3.8 calls usual in applications.

The theorem with its addendum `Chapter15/GeneralPositionExistence · SBLocalization.theorem_15_3_7`. (1)–(4) always, and Λ structurable whenever a good system exists.

The intermediate statements are steps of these two proofs. Each one proves the structurable form from a hypothesis that another step of the proof discharges: - `theorem_15_3_7_hyp` and `theorem_15_3_7_of_hyp` (local families and parametric general position; §XV.22); - `theorem_15_3_7_hyp_seeds` and `theorem_15_3_7_of_seeds` (local seeds; §XV.23); - `theorem_15_3_7_of_pointwise` (the two facts at single points; §XV.23); - `theorem_15_3_7_hyp_local` and `theorem_15_3_7_of_local` (local families alone; §XV.25); - the form from the two facts and a good system `Chapter15/GeneralPositionPointwise · SBLocalization.theorem_15_3_7_of_param0nto`, which the structurable addendum specializes by proving the two facts.

Each has its hypotheses satisfied on $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$: - a good system there, by Theorem 13.1.8 on $\mathbb{R}^n$ `Chapter15/GeneralPositionAssembly · SBLocalization.nonempty_goodSystem_epSEP_zero`; - lo-

cal families with $\ell = 0$ for every f, N, U, h Chapter15/GeneralPositionAssembly · SBLocalization.hasLocalGPFamilies_epSEP_zero; - parametric general position, since every pair is in general position there Chapter15/GeneralPositionAssembly · SBLocalization.hasParametricGeneralPosition_epSEP_zero; - local seeds Chapter15/LocalFamilies · SBLocalization.hasLocalParamSeeds_epSEP_zero; - small vectors with $\ell = 0$ Chapter15/LocalSeeds · SBLocalization.hasPointwiseParamOnto_epSEP_zero and openness Chapter15/LocalSeeds · SBLocalization.hasParamOntoOpen_epSEP_zero, both resting on (15.1) being automatic with zero fibres Chapter15/LocalSeeds · SBLocalization.isParamOntoVec_epSEP_zero.

The conclusion holds there in each form: - Chapter15/GeneralPositionAssembly · SBLocalization.theorem_15_3_7_statement_epSEP_zero_of_hyp - Chapter15/LocalFamilies · SBLocalization.theorem_15_3_7_statement_epSEP_zero_of_seeds - Chapter15/LocalSeeds · SBLocalization.theorem_15_3_7_statement_epSEP_zero_of_pointwise - Chapter15/ParametricGeneralPosition · SBLocalization.theorem_15_3_7_statement_epSEP_zero_of_local - Chapter15/GeneralPositionPointwise · SBLocalization.theorem_15_3_7_statement_epSEP_zero_of_paramOnto - Chapter15/GeneralPositionGoodSystem · SBLocalization.theorem_15_3_7_statement_epSEP_zero_of_goodSystem

These witnesses are weak: the fibres are zero and there is no boundary, so every pair is in general position. They show only that the intermediate statements are not vacuous. The final theorems need no such witness, since all their added hypotheses are discharged, except the inherited tame germ data and, for the addendum, the necessary good system.

Remark 15.3.8 (nothing to formalize). The remark says the theorem does not assume a paracompact orbit space, only an auxiliary norm, and that constructing auxiliary norms usually needs paracompactness of $|X|$. - In the formalization, (1)–(4) need neither paracompactness nor a good system. The auxiliary norm enters only through "(N, U) controls compactness". - The addendum "structurable" needs a good system. Paracompactness supplies one (Theorem 13.1.8), and so does any structurable multisection.

So the remark holds as read for (1)–(4). For the addendum, paracompactness, or at least a good system, does enter. The part of gap G.162 that concerns Theorem 15.3.7 is closed.

XV.27 Theorem 15.3.9 (2017: 15.5): the statement, the face condition, and charging

Theorem 15.3.9, the Transversal Extension Theorem (p. 698), extends a perturbation given over the boundary to a perturbation over all of X that is transversal, without changing it over ∂X. It is the tool for the cobordism part of Corollary 15.3.10 (§XV.33), where the boundary data are two regular perturbations sitting at the ends of the cylinder $[0, 1] \times X$. Its proof (pp. 698–699) has five steps: (a) a cut-off functor h_0 between $N(\Lambda)$ and h; (b) Theorem 14.1.9, which extends Λ to a structurable Λ_0 with $N(\Lambda_0) \le h_0$; (c) transversality of (f, Λ_0) near ∂X, from the hypothesis on the faces; (d) the argument of Theorem 15.3.7 away from ∂X, with families Λ_t whose domain support avoids ∂X; (e) $\tilde{\Lambda} = \Lambda_t \oplus \Lambda_0$ for a small regular t. The formalization follows these steps in this order. This subsection gives the definitions, the statement as formalized and the property of the uncharged Lean statement; step (a) is §XV.28, steps (b)–(e) are §XV.29.

General position at one point. For a level-1 point x, (f, Λ) is *reducedly onto at* x if every operator L in the support of $T(f, \Lambda)(x)$ (Definition 15.1.7, §XV.8) restricts to a surjection $T^R_x X \to W_x$, the reduced tangent space $T^R_x X$ being read in every chart of X around x and every presentation of the partial quadrant of its model Chapter15/TransversalExtension · SBLocalization.IsReducedOntoAtPt. This is Definition 15.3.5 at one point: (f, Λ) is in general position iff it is reducedly onto at every level-1 point of $\mathrm{supp}(\Lambda \circ f)$, by def-

inition Chapter15/TransversalExtension · SBLocalization.isInGeneralPosition_iff_forall_reducedOntoAtPt (it is the same predicate as the pointwise general position of §XV.16, Chapter15/GeneralPositionLocal · SBLocalization.IsInGeneralPositionAt, there with the level-1 membership as a separate clause). In general position (f, Λ) is transversal: every operator of the support is onto on the larger space $T_xX \supseteq T^R_xX$, and the support points are at level 1 Chapter15/TransversalExtension · SBLocalization.IsInGeneralPosition.isTransversal Chapter15/ControllingPairs · SBLocalization.mem_levelSet_one_of_pos.

The boundary data. Chapter 14's objects over ∂X are used as Part XIV formalizes them. An *sc⁺-multisection over ∂X* (Definition 14.1.3) is a function $\Lambda : W \to \mathbb{Q}^+$ of which only the values over ∂X enter: it is a functor on $W|\partial X$, and every $x \in \partial X$ has a good neighbourhood $U(x) = V(x) \cap \partial X$ carrying a *symmetric sc⁺-section structure*, a finite index set I_x with a G_x-action and sections s_i that are sc⁺ on the faces (Definition 14.1.3 (1)), equivariant (2), and represent Λ by $\Lambda(w) = |I_x|^{-1}\#\{i : s_i(P(w)) = w\}$ (3) Chapter14/BoundaryMultisection · SBLocalization.IsBoundaryScPlusMultisection Chapter14/BoundaryMultisection · SBLocalization.BoundarySymmetricStructure. It is *structurable over ∂X* (Definition 14.1.7) if it carries in addition a decoration and a family of index correspondences Chapter14/BoundaryStructured · SBLocalization.IsBoundaryStructurable. Its *boundary domain support* is the closure of the set of $x \in \partial X$ over which Λ charges a non-zero vector Chapter14/BoundaryStructured · SBLocalization.boundaryDomSupp. Finally, Λ *charges* ∂X if over every $x \in \partial X$ some w has $\Lambda(w) \neq 0$ Chapter14/EmptyIndex · SBLocalization.ChargesBoundary. For a symmetric structure at a charged point the index set is not empty, because the formula (3) with $I_x = \emptyset$ gives $\Lambda = 0$ on the fibre Chapter14/EmptyIndex · SBLocalization.BoundarySymmetricStructure.nonempty_I_a6. The formal Definition 14.1.3 admits $I_x = \emptyset$, while the text's $|I_x|^{-1}$ presumes $I_x \neq \emptyset$; charging is the reading of the text's definition that excludes the empty index sets (Theorem 14.1.9, Part XIV).

The face condition Chapter15/TransversalExtension · SBLocalization.IsBoundaryFaceOnto. The text asks that $T_{(f|\partial X,\Lambda)}(x)$ be "surjective with respect to intersections of local faces" at every smooth $x \in \partial X$. It is read as follows: for every sc⁺-multisection Λ' on W that agrees with Λ over ∂X, and every smooth level-1 point $x \in \partial X$ with $\Lambda(f(x)) > 0$, (f, Λ') is reducedly onto at x. Two readings are in this. (i) The intersections of the tangent spaces of the local faces through x form a family whose smallest member is T^R_xX (Part I, Definition 2.5.8), and surjectivity on a subspace implies surjectivity on every larger one; so the condition for all intersections is the condition on T^R_xX, which is general position at x. (ii) $T(f|\partial X, \Lambda)$ is not defined by the text: Λ lives only over ∂X, and its linearization needs local sections near x, not only on the faces. The restriction of $(f - s_i)'(x)$ to T^R_xX sees only the values of s_i on the faces through x, so it should not depend on how Λ is extended; the formal condition is therefore asked for every sc⁺ extension Λ'. That it does not depend on the extension is not proved (gap G.179, §XV.38); in the proof the condition is used for exactly one extension, the Λ_0 of step (b) (§XV.29).

Statement (narrower) Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_statement. Let $(P : W \to X, \mu)$ be a strong bundle over a tame ep-groupoid with $|X|$ paracompact, whose object M-polyfold admits sc-smooth partitions of unity, and every object of which lies in a tame strong bundle chart. Let f be an sc-Fredholm section functor with Part I's tame germ data and compact $|S_f|$, and (N, U) control compactness (Definition 15.3.1, §XV.17; U open and saturated). Let Λ be structurable over ∂X and charge ∂X, with boundary domain support in U and $N(\Lambda) \leq 1$ on ∂X, and let $h : X \to (0, 1]$ be a continuous functor with $N(\Lambda)(x) < h(x)$ for $x \in \partial X$. Assume the face condition. Then there is a structurable sc⁺-multisection $\tilde{\Lambda}$ with

1. $\tilde{\Lambda} = \Lambda$ over ∂X;
2. domain support in U, $N(\tilde{\Lambda}) < h$ everywhere, and $\tilde{\Lambda}$ (N, U)-admissible (Definition 15.3.3, §XV.18);

3. $(f, \tilde{\Lambda})$ transversal (Definition 15.2.1, §XV.12);

and $\tilde{\Lambda} \circ f$ is a branched ep⁺-subgroupoid with compact support.

Readings. "U a saturated subset" is read as open and saturated, which Definition 15.3.1 contains. "Λ is (U, N)-admissible" over ∂X is read as boundary domain support in U and $N(\Lambda) \leq 1$ on ∂X, the two parts of Definition 15.3.3 that make sense over ∂X. "Onto on $\operatorname{supp}(\tilde{\Lambda} \circ f)$" is transversality. The word "tame" of the "moreover" is not in the formal conclusion: the $\tilde{\Lambda}$ that the proof produces is in general position (§XV.29), and for such a $\tilde{\Lambda}$ the tame form of the "in particular" of Theorem 15.3.7 (§XV.21) gives a tame branched ep⁺-subgroupoid, but the statement as formalized exports only the text's (1)–(3) with "branched" and "compact".

Narrower, by four hypotheses, of which two are readings and two are open. **Tame strong bundle charts** at every object: the reading of "a strong bundle over a tame ep-groupoid" that Part XIV uses for Theorem 14.1.9; it is needed in step (a) (§XV.28), not derived from the text, and it has a witness with boundary and non-zero fibres, the trivial bundle $[0,\infty) \times \mathbb{R}^m \times \mathbb{R}^k \to [0,\infty) \times \mathbb{R}^m$ of Part XIV `Chapter14/HalfSpaceBundle · HalfSpaceBundle.hB_halfSEP`, as well as one without boundary `Chapter14/OpenExtension · SBLocalization.proposition_14_1_4_hypotheses_rn`. **Charging** of ∂X by Λ: the reading $I_x \neq \emptyset$ of "sc⁺-multisection over ∂X". It is necessary: if a structurable $\tilde{\Lambda}$ agrees with Λ over ∂X, then Λ charges ∂X `Chapter15/ChargedExtensionFibres · SBLocalization.chargesBoundary_of_theorem_15_3_9_r6`, because a local representation of $\tilde{\Lambda}$ at $x \in \partial X$ (Definition 13.2.1) has weights summing to 1, so it has a branch s_i, and $\tilde{\Lambda}(s_i(x)) \geq \sigma_i > 0$ `Chapter14/EmptyIndex · SBLocalization.chargesBoundary_of_structurable_eq_a6`. The zero multisection charges every fibre `Chapter14/EmptyIndex · SBLocalization.chargesBoundary_zeroMultisection_a6`, and the boundary hypotheses of Theorem 14.1.9 with charging hold together on the half-space bundle, whose boundary is not empty `Chapter14/HalfSpaceBundle · HalfSpaceBundle.theorem_14_1_9_charged_hypotheses_halfSEP`. The **tame germ data** of f are inherited from §15.2 and Part I's Theorem 3.6.8, as everywhere in this Part. The **face condition for every extension** is the reading (ii) above (gap G.179). Partitions of unity on the objects and the paracompactness of $|X|$ are the text's.

The theorem (narrower) `Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_of_local_rel`. The charged statement holds for every strong bundle for which the *relative local families* exist `Chapter15/ChargedExtensionFibres · SBLocalization.relative_local_families_statement`: under the hypotheses of steps (c)–(d), every point of $\operatorname{supp}(\Lambda_0 \circ f)$ lies in a saturated open set carrying a parameter family with domain support in $U \setminus \partial X$, the bound $N(\Lambda_t) \leq |t|_1(h - N(\Lambda_0))$ and the relative form of (15.1) (§XV.29). This is the one analytic input of the proof that is not formalized, gap G.178: everything else, the cut-off, Theorem 14.1.9, the relative parametric transversality, the compactness and the assembly, is proved. *Witnesses*: the relative local families and the charged statement hold on the trivial bundle $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$ `Chapter15/ChargedExtensionFibres · SBLocalization.relative_local_families_statement_epSEP_zero` `Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_statement_epSEP_zero`, where $\partial X = \emptyset$ `Chapter15/TransversalExtension · SBLocalization.boundary_epSEP_eq_empty` and the fibres are zero, so every pair is in general position. These witnesses are **weak**: no strong bundle with boundary is known to satisfy the relative local families, and the theorem has no non-degenerate witness.

Remark: the uncharged Lean statement. The uncharged Lean statement `Chapter15/TransversalExtension · SBLocalization.theorem_15_3_9_statement` is the charged statement without the tame strong bundle charts and without charging; the charged statement follows from it `Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_of_statement`. As a Lean statement it does not hold when $\partial X \neq \emptyset$ and one sc-Fredholm f with tame germ data, compact $|S_f|$ and a pair (N, U) controlling compactness exists `Chapter15/ChargedExtensionCylinder · SBLocalization.not_theorem_15_`

3_9_statement_w2. *Proof.* Take $\Lambda \equiv 0$. It is structurable over ∂X in the formal sense, with empty index sets Chapter14/EmptyIndex · SBLocalization.isBoundaryStructurable_zeroFun_a6; its boundary domain support is empty Chapter14/EmptyIndex · SBLocalization.boundaryDomSupp_zeroFun_a6; its pointwise norm is 0, its support over every point being empty Chapter15/ChargedExtensionCylinder · SBLocalization.pointwiseNorm_zeroFun_w2; with $h \equiv 1$ the norm conditions hold, and the face condition holds vacuously since $\Lambda(f(x)) = 0$. The statement would give a structurable $\tilde{\Lambda}$ vanishing over ∂X, and no structurable multisection vanishes over a point (the necessity of charging above). On the cylinder $[0,1] \times X$ of §XV.30, with $d_X \equiv 0$ and X nonempty, the hypotheses of Corollary 15.3.10 provide all of this: the cylinder is tame since X is (§XV.30), its orbit space is paracompact, $(0,x)$ lies on its boundary, $\tilde{f}$ is sc-Fredholm with tame germ data and compact solution set, and Corollary 15.3.10 (2) gives a controlling pair; so the uncharged statement fails on every such cylinder Chapter15/ChargedExtensionCylinder · SBLocalization.not_theorem_15_3_9_statement_cube_w2. This is a property of our formalization, not of the text, whose Λ has non-empty index sets; it has the same source as the failure of the uncharged Lean statement of Theorem 14.1.9 (Part XIV). *Consequences.* The Lean forms that conclude the uncharged statement are correct implications whose hypotheses fail when $\partial X \neq \emptyset$; they are vacuous there and are used only as intermediate steps for $\partial X = \emptyset$: the reduction to Theorem 14.1.9 and two proof steps Chapter15/TransversalExtension · SBLocalization.theorem_15_3_9_hyp, its form with step (a) proved Chapter15/CutoffFunctor · SBLocalization.theorem_15_3_9_of_extension_ty, and its forms with the relative parametric step proved Chapter15/RelativeReduction · SBLocalization.theorem_15_3_9_of_rel_hyp Chapter15/RelativeParametric · SBLocalization.theorem_15_3_9_of_local_rel, which take the uncharged extension statement of Theorem 14.1.9 as a hypothesis. The forms of Corollary 15.3.10 (3) that take the uncharged statement on the cylinder are vacuous for nonempty X (§XV.33). The charged statement, built on Theorem 14.1.9 in its charged form (Part XIV), replaces all of them, and the rest of this subsection and §§XV.28–XV.29 tell its proof. The uncharged statement does hold on the boundaryless example, where its three propositional inputs hold as well Chapter15/TransversalExtension · SBLocalization.theorem_15_3_9_statement_epSEP_zero Chapter15/TransversalExtension · SBLocalization.lemma_15_3_9_cutoff_statement_epSEP_zero Chapter15/TransversalExtension · SBLocalization.theorem_15_3_7_relative_statement_epSEP_zero: there $\Lambda_0 = 0$ has every conclusion, being in general position Chapter15/GeneralPositionBranched · SBLocalization.isInGeneralPosition_epSEP_zero, and the boundary domain support is empty Chapter15/TransversalExtension · SBLocalization.boundaryDomSupp_epSEP.

The shape of the proof Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_hyp. The charged statement follows from the *relative statement*, the proposition that steps (c)–(d) produce Chapter15/TransversalExtension · SBLocalization.theorem_15_3_7_relative_statement: given a structurable Λ_0 with domain support in U, $N(\Lambda_0) < h$, and (f, Λ_0) reducedly onto at the points of $\operatorname{supp}(\Lambda_0 \circ f) \cap \partial X$, there is a structurable $\tilde{\Lambda}$ equal to Λ_0 over ∂X, with domain support in U, $N(\tilde{\Lambda}) < h$, transversal and in general position. The relative statement follows from the relative local families alone Chapter15/RelativeParametric · SBLocalization.theorem_15_3_7_relative_of_local, the parametric step being proved. §XV.28 proves step (a); §XV.29 retells steps (b)–(e) and the proof of the relative statement.

XV.28 Proof of Theorem 15.3.9, step (a): the cut-off functor h_0

Statement (explicit) Chapter15/CutoffFunctor · SBLocalization.lemma_15_3_9_cutoff_hyp. If every object lies in a tame strong bundle chart, then step (a) holds Chapter15/TransversalExtension · SBLocalization.lemma_15_3_9_cutoff_statement: for X tame with $|X|$ paracompact and sc-smooth partitions of unity, Λ an sc$^+$-multisection over ∂X, N an auxiliary norm, U open and saturated containing the boundary domain

support of Λ, and $h > 0$ a continuous functor with $N(\Lambda) < h$ on ∂X, there is a continuous functor $h_0 \geq 0$ with tsupp $h_0 \subset U$, $h_0 < h$ everywhere, and $N(\Lambda) < h_0$ on the boundary domain support of Λ. These are the hypotheses that Theorem 14.1.9 asks of its function f with $\tilde{U} = U$, and the margin $h_0 < h$ is used at the end of the proof.

A reading. The text asks for h_0 with $N(\Lambda)(x) < h_0(x) < h(x)$ for every $x \in \partial X$ and h_0 supported in U. Off the boundary domain support, over ∂X, the support of Λ is the zero vector and $N(\Lambda) = 0$; at a point of ∂X outside U the two requirements would ask $0 < h_0 = 0$. So the strict lower bound is presumably meant on the domain support, which is what Theorem 14.1.9 asks; the formal statement says so. The text's $h_0 \leq 1$ is not needed, $h_0 < h \leq 1$ holding anyway in the application.

Proof. Write C for the boundary domain support of Λ. Four facts about Λ come first.

The support over a boundary point. If S is a symmetric structure of Λ on $V(x)$ and $y \in V(x) \cap \partial X$, then w lies in the support of Λ over y iff $w = s_i(y)$ for some i `Chapter15/CutoffFunctor · SBLocalization.BoundarySymmetricStructure.mem_suppAt_iff_ty`: by the representation formula (3), $\Lambda(w) > 0$ iff the count $\#\{i : s_i(y) = w\}$ is positive, the index set being non-empty as soon as it contains one i. In particular the support over ∂X lies in $W_{0,1}$, each s_i being sc$^+$ on the faces `Chapter15/CutoffFunctor · SBLocalization.IsBoundaryScPlusMultisection.suppAt_subset_oneSet_ty`, so the pointwise norm $N(\Lambda)(y) = \sup\{N(w) : \Lambda(w) > 0\}$ is the maximum of the finitely many $N(s_i(y))$.

$N(\Lambda)$ is a functor on ∂X `Chapter15/CutoffFunctor · SBLocalization.pointwiseNorm_tgt_of_boundary_ty`. For a morphism φ with source in ∂X, $\mu(\varphi, \cdot)$ carries the support over $s(\varphi)$ into the support over $t(\varphi)$, since Λ is a functor on $W|\partial X$, and it preserves N, since an auxiliary norm is invariant under μ `Chapter13/AtomicConstruction · SBLocalization.normW_μ`; so the set of norms over $s(\varphi)$ lies in that over $t(\varphi)$ `Chapter15/CutoffFunctor · SBLocalization.normW_image_suppAt_subset_ty`, and the inverse morphism, whose source again lies in the saturated set ∂X, gives the other inclusion.

C is saturated `Chapter15/CutoffFunctor · SBLocalization.isSaturated_boundaryDomSupp_ty`. The set of $x \in \partial X$ over which Λ charges a non-zero w is saturated: $\mu(\varphi, w)$ is charged over $t(\varphi)$, and it is not zero, since $N(\mu(\varphi, w)) = N(w) > 0$, an auxiliary norm vanishing only at zero vectors. The closure of a saturated set is saturated. And $C \subset \partial X$, ∂X being closed `Chapter15/CutoffFunctor · SBLocalization.boundaryDomSupp_subset_boundary_ty`.

$N(\Lambda)$ is upper semicontinuous along ∂X `Chapter15/CutoffFunctor · SBLocalization.exists_nhds_pointwiseNorm_lt_ty`: for $x \in \partial X$ and $c > N(\Lambda)(x)$ there is an open $O \ni x$ with $N(\Lambda) < c$ on $O \cap \partial X$. Take a symmetric structure on $V(x)$. Its sections s_i are sc$^+$ only on the faces; with tame strong bundle charts at every object and sc-smooth partitions of unity, each extends to an sc$^+$-section $\bar{s}_i$ on the open set $V(x)$ with $\bar{s}_i = s_i$ on $V(x) \cap \partial X$ `Chapter14/OpenExtension · SBLocalization.exists_scPlusSectionOn_extension_of_face` (the extension lemma of Part XIV behind Proposition 14.1.4). The functions $y \mapsto N(\bar{s}_i(y))$ are continuous on $V(x)$. With $c' = (N(\Lambda)(x) + c)/2$, the set $O = V(x) \cap \bigcap_i \{N \circ \bar{s}_i < c'\}$ is open, contains x because $N(s_i(x)) \leq N(\Lambda)(x) < c'$, and on $O \cap \partial X$ every norm $N(s_i(y)) = N(\bar{s}_i(y))$ is below c', so $N(\Lambda)(y) \leq c' < c$. This is the only place where the tame strong bundle charts enter. Without them Definition 14.1.3 (1) constrains the s_i only face by face, and nothing prevents $N(\Lambda)$ from jumping up along ∂X; the text uses the semicontinuity without comment.

Construction of g on $|X|$. The orbit space $|X|$ is paracompact and Hausdorff. For an orbit q let

$$t(q) = \{y \geq 0 : y < h(x) \text{ and, if } x \in C,\ y > N(\Lambda)(x),\ \text{for every } x \text{ with } \pi(x) = q\},$$

an intersection of intervals, hence convex. Since h and $N(\Lambda)|_{\partial X}$ are constant on orbits and C is saturated, $t(q)$ is described by any one x over q. Each $q = \pi(x)$ has a constant c that lies in $t(q')$ for all q' near q. If $x \in C$, take $c = (N(\Lambda)(x) + h(x))/2$: by the upper semicontinuity there is an open $O \ni x$ with $N(\Lambda) < c$ on $O \cap \partial X$, and $h > c$ on an open neighbourhood by continuity; if $x \notin C$, take $c = h(x)/2$ on $(X \setminus C) \cap \{h > h(x)/2\}$, open since C is closed. In both cases the open set maps to an open neighbourhood of q, the orbit map being open (Proposition 7.1.8) `Chapter7/Basic · EpGroupoid.proposition_7_1_8`, and the invariance of the data transfers the inequalities from the chosen representatives to all points of the orbits. Mathlib's selection lemma for convex-valued maps with local constant selections on a paracompact space `Mathlib/Analysis/Convex/PartitionOfUnity · exists_continuous_forall_mem_convex_of_local_const`, a partition of unity argument, gives a continuous $g : |X| \to \mathbb{R}$ with $g(q) \in t(q)$ for all q: $0 \le g < h$, and $g > N(\Lambda)$ on $\pi(C)$.

The Urysohn factor. $\pi(C)$ is closed in $|X|$, C being closed and saturated `Chapter14/BoundaryCover · EpGroupoid.isClosed_π_image_of_isSaturated`, and $\pi(U)$ is open and contains it. By normality there is an open V with $\pi(C) \subset V$ and $\operatorname{cl} V \subset \pi(U)$, and an Urysohn function $\psi : |X| \to [0,1]$ with $\psi = 1$ on $\pi(C)$ and $\psi = 0$ off V.

The functor. $h_0 = (\psi g) \circ \pi$. It is continuous, non-negative, constant on orbits, hence a functor. Its topological support lies in $\pi^{-1}(\operatorname{cl} V) \subset \pi^{-1}(\pi(U)) = U$, U being saturated. $h_0 \le g \circ \pi < h$, since $0 \le \psi \le 1$. On C, $\psi = 1$ and $h_0 = g \circ \pi > N(\Lambda)$. □

The added hypothesis, tame strong bundle charts at every object, is not stated in the theorem; it is the reading of the standing assumption used for Theorem 14.1.9 in Part XIV. Witnesses: the trivial bundle over $\mathbb{R}^n$ `Chapter14/OpenExtension · SBLocalization.proposition_14_1_4_hypotheses_rn`, with $\partial X = \emptyset$, and the half-space bundle, with boundary and non-zero fibres `Chapter14/HalfSpaceBundle · HalfSpaceBundle.hB_halfSEP`. On $\mathbb{R}^n \times \mathbb{R}^0$ the cut-off statement holds trivially with $h_0 = 0$, the boundary domain support being empty `Chapter15/TransversalExtension · SBLocalization.lemma_15_3_9_cutoff_statement_epSEP_zero`. Gap G.177 is closed.

XV.29 Proof of Theorem 15.3.9, steps (b)–(e): relative general position and the assembly

This subsection follows the proof of the charged theorem `Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_hyp` after the cut-off of §XV.28, and then the proof of the relative statement that steps (c)–(d) supply.

Step (b): the extension Λ_0. Apply Theorem 14.1.9 in its charged form (Part XIV) `Chapter14/BoundaryExtensionTheorem · SBLocalization.theorem_14_1_9_charged_a6` to Λ, with $\tilde{U} = U$ and the function h_0 of step (a). Its hypotheses are those of Theorem 15.3.9 together with the properties of h_0: X tame, $|X|$ paracompact, partitions of unity, tame strong bundle charts, Λ structurable over ∂X and charging ∂X, N an auxiliary norm, U open, saturated and containing the boundary domain support, $h_0 \ge 0$ a continuous functor with topological support in U, and $N(\Lambda) < h_0$ on the boundary domain support `Chapter14/BoundaryExtensionTheorem · SBLocalization.theorem_14_1_9_charged_statement`. It gives a structurable Λ_0 with $N(\Lambda_0) \le h_0$ everywhere, domain support in U, and $\Lambda_0 = \Lambda$ over ∂X. In particular $N(\Lambda_0) \le h_0 < h$ everywhere. *A reading*: after applying Theorem 14.1.9 the text writes "$N(\Lambda_0)(x) \le h(x)$"; presumably $\le h_0(x)$ is meant, since the margin $h_0 < h$ is what makes the final $N(\tilde{\Lambda}) < h$ strict.

Step (c): general position of Λ_0 on the boundary. For a level-1 point $x \in \partial X$ with $\Lambda_0(f(x)) > 0$, (f, Λ_0) is reducedly onto at x. Indeed $f(x)$ lies over $x \in \partial X$, where $\Lambda_0 = \Lambda$, so $\Lambda(f(x)) > 0$; x is a

smooth point, every point of $\operatorname{supp}(\Lambda_0 \circ f)$ being smooth under the tame germ data, since $f(x)$ is then the value of an sc⁺-section and $f - s$ is regularizing `Chapter15/Transversality · SBLocalization.mem_smoothSet_of_pos`; and Λ_0 is an sc⁺-multisection on W that agrees with Λ over ∂X, so the face condition applies to it. The text says at this point that the boundary assumption gives, for every boundary point of the support, a neighbourhood $Q(x)$ on which the reduced linearization of (f, Λ_0) is onto; the formal proof takes the condition at the boundary support points only and leaves the neighbourhood to the local families (below).

Steps (c)–(d): the relative statement. Its hypotheses hold for Λ_0: structurable, domain support in U, $N(\Lambda_0) < h$, reducedly onto at the boundary support points. It gives a structurable $\tilde{\Lambda}$ with $\tilde{\Lambda} = \Lambda_0$ over ∂X, domain support in U, $N(\tilde{\Lambda}) < h$, $(f, \tilde{\Lambda})$ transversal and in general position. Its proof is the rest of this subsection.

Step (e): the conclusions. $\tilde{\Lambda} = \Lambda_0 = \Lambda$ over ∂X. Since $h \le 1$, $N(\tilde{\Lambda}) \le 1$, and with the domain support in $U \supseteq S_f$ the example after Definition 15.3.3 (§XV.18) makes $\tilde{\Lambda}$ admissible `Chapter15/ControllingPairs · SBLocalization.isAdmissible_of_domSupp_subset`. The "moreover": general position, $N(\tilde{\Lambda}) \le 1$ and domain support in U are the hypotheses of the "in particular" of Theorem 15.3.7 (§XV.21) `Chapter15/GeneralPositionBranched · SBLocalization.theorem_15_3_7_in_particular_hyp`, which gives a branched ep⁺-subgroupoid with compact support. □

The proof of the relative statement is "argue as in Theorem 15.3.7" (p. 698), made precise. The text takes parameter families Λ_t with domain support away from ∂X and asks of $\Lambda_t \oplus \Lambda_0$ near $(0, x)$, x in the support, that the reduced linearization of the parametrized problem be onto. The formalization reads this as (15.1) relative to the branches of Λ_0, and then repeats the three parts of the proof of Theorem 15.3.7 (§§XV.22–XV.25): the assembly of local families, the parametric transversality, and the choice of t.

Relative (15.1) `Chapter15/RelativeFamilies · SBLocalization.IsParamOntoAtRel`. Let $t \mapsto \Lambda_t$, $t \in \mathbb{R}^\ell$, be a family of sc⁺-multisections and x a level-1 point. The family satisfies (15.1) relative to Λ_0 at x if it has, on an open $O \ni x$, a linear local representation by the sections $\sum_j t_j s_{ij}$ with weights σ_i independent of t (as in §XV.22, `Chapter15/ParamFamily · SBLocalization.paramSec`), and for every operator L in the support of $T(f, \Lambda_0)(x)$, every chart presentation of $T^R_x X$ and every branch i, the map

$$T^R_x X \times \mathbb{R}^\ell \to W_x, \quad (v, \tau) \mapsto Lv + \sum_j \tau_j s_{ij}(x)$$

is onto. The operators of $T(f, \Lambda_0)(x)$ are the $(f - s^0_a)'(x)$ for the branches s^0_a of Λ_0 through $f(x)$ (§XV.12); the text's (15.1) has the operators of $T(f, 0)(x)$, which is the case $\Lambda_0 = 0$ `Chapter15/RelativeFamilies · SBLocalization.isParamOntoAtRel_zero_iff`. Two properties. *Where (f, Λ_0) is already reducedly onto*, relative (15.1) holds for every linear family, with $\tau = 0$ `Chapter15/RelativeFamilies · SBLocalization.IsParamOntoAtRel.of_reducedOnto`; this is how step (c) feeds steps (c)–(d) at the boundary support points. *Sums*: if one summand satisfies relative (15.1) and the other is linear, the sum family $\Lambda_t \oplus \Lambda'_{t'}$ on $\mathbb{R}^{\ell+\ell'}$ does `Chapter15/RelativeFamilies · SBLocalization.IsParamOntoAtRel.famAdd_left` `Chapter15/RelativeFamilies · SBLocalization.IsParamOntoAtRel.famAdd_right`. The sum family is linear with the branches $\sum_j t_j s_{ij} + \sum_k t'_k s'_{i'k}$ on the intersection of the two domains `Chapter15/ParamFamily · SBLocalization.famAdd` `Chapter15/ParamFamily · SBLocalization.isLocalRepOn_famAdd`; given (v, τ) for the branch i of the first family, $(v, (\tau, 0))$ serves for every branch (i, i') of the sum.

Relative families `Chapter15/RelativeFamilies · SBLocalization.RelGPFamily`. For a function g and a set Q: a linear family `Chapter15/ParamFamily · SBLocalization.IsLinearFamily` of structurable sc⁺-multisections

with $N(\Lambda_t)(x) \le |t|_1\, g(x)$, domain support in a given U', and relative (15.1) at every level-1 point of $\operatorname{supp}(\Lambda_0 \circ f) \cap Q$. In the application $g = h - N(\Lambda_0)$ and $U' = U \setminus \partial X$. The family of Theorem 15.3.7 (§XV.22) is the case $\Lambda_0 = 0$, $g = h$. A family on Q is one on every smaller set `Chapter15/RelativeFamilies · SBLocalization.RelGPFamily.mono`. Given a good system, the parameter-free family $\Lambda_t = 0$ ($\ell = 0$), which is linear `Chapter15/RelativeFamilies · SBLocalization.isLinearFamily_zero` and structurable `Chapter15/ParamFamily · SBLocalization.isStructurable_zeroMultisection_of_goodSystem`, is a relative family on every set on which (f, Λ_0) is reducedly onto at the support points `Chapter15/RelativeFamilies · SBLocalization.RelGPFamily.zeroOn`, in particular on $\emptyset$ `Chapter15/RelativeFamilies · SBLocalization.RelGPFamily.zero`. Two families on Q and Q' add to one on $Q \cup Q'$ `Chapter15/RelativeFamilies · SBLocalization.RelGPFamily.add`: the sum of structurable multisections is structurable (Proposition 13.3.12) `Chapter13/StructurableMultisection · SBLocalization.proposition_13_3_12`; the norm of a sum is at most the sum of the norms `Chapter15/ParamFamily · SBLocalization.pointwiseNorm_multisectionAdd_le`, so $N \le (|t|_1 + |t'|_1)g = |(t,t')|_1\, g$; the domain support of a sum lies in the union `Chapter15/ParamFamily · SBLocalization.domSupp_multisectionAdd_subset`; and relative (15.1) passes to sums from either summand.

Off the domain support. An sc⁺-multisection is the zero multisection over every point outside its domain support `Chapter15/RelativeFamilies · SBLocalization.eq_zeroMultisection_of_notMem_domSupp`: in a local representation at that point every branch passes through the zero vector, for otherwise the point would be in the domain support, so $\Lambda(0_x) = \sum_i \sigma_i = 1$ and $\Lambda = 0$ elsewhere on the fibre. Hence $\Lambda_0 \oplus \Lambda = \Lambda_0$ over every point outside the domain support of Λ `Chapter15/RelativeFamilies · SBLocalization.multisectionAdd_eq_left_of_notMem_domSupp`, the zero multisection being neutral for $\oplus$ (Part XIII) `Chapter13/MultisectionNoInverse · SBLocalization.multisectionAdd_zeroMultisection`. This is what "domain support away from ∂X" achieves: $\Lambda_0 \oplus \Lambda_t = \Lambda_0$ over ∂X.

The two analytic steps, relative to Λ_0, as propositions. *The relative local families* `Chapter15/RelativeReduction · SBLocalization.HasLocalGPFamiliesRel`: every x with $\Lambda_0(f(x)) > 0$ lies in an open saturated Q carrying a relative family. *The relative parametric transversality* `Chapter15/RelativeReduction · SBLocalization.HasParametricGeneralPositionRel`: for every linear family of sc⁺-multisections with $N(\Lambda_t) \le |t|_1(1 - N(\Lambda_0))$, domain support in U and relative (15.1) at every point of $\operatorname{supp}(\Lambda_0 \circ f)$, there is $\varepsilon > 0$ such that $(f, \Lambda_0 \oplus \Lambda_t)$ is in general position for almost every t with $\|t\| < \varepsilon$.

The relative statement from the two steps `Chapter15/RelativeReduction · SBLocalization.theorem_15_3_7_relative_hyp`. Let Λ_0 be structurable with domain support in U and $N(\Lambda_0) < h \le 1$, and assume the relative local families with domain support in $U \setminus \partial X$ and $g = h - N(\Lambda_0)$, and the relative parametric transversality. *Step 1, a good system.* A structurable Λ_0 carries a decoration, whose good system is all that the empty family needs. *Step 2, compactness of the support.* $|\operatorname{supp}(\Lambda_0 \circ f)|$ is compact `Chapter15/RelativeReduction · SBLocalization.isCompact_image_supp_comp`: with $N(\Lambda_0) \le 1$ and domain support in U this is the compactness of the "in particular" of Theorem 15.3.7 (§XV.21) `Chapter15/GeneralPositionBranched · SBLocalization.isCompact_orbitSupp_comp`, read as a statement about the image of $\{x : \Lambda_0(f(x)) > 0\}$ in $|X|$. *Step 3, from local to global* `Chapter15/RelativeReduction · SBLocalization.exists_relGPFamily_of_compact`. The images $\pi(Q_x)$ of the sets of the local families are open (Proposition 7.1.8) and cover the compact set of Step 2; finitely many suffice; the families on them add, by induction over the finite set starting from the empty family `Chapter15/RelativeReduction · SBLocalization.nonempty_relGPFamily_biUnion`, to one relative family F on a set Q that contains $\operatorname{supp}(\Lambda_0 \circ f)$, the Q_x being saturated. *Step 4, a regular parameter.* F satisfies the hypotheses of the relative parametric transversality: its domain support lies in $U \setminus \partial X \subset U$, and $|t|_1(h - N(\Lambda_0)) \le |t|_1(1 - N(\Lambda_0))$ since $h \le 1$. So for some

$\varepsilon > 0$, almost every t with $\|t\| < \varepsilon$ gives general position. A ball has positive measure, so there is such a t with $\|t\| < \min(\varepsilon, 1/(\ell+1))$ Chapter15/GeneralPositionAssembly · SBLocalization.exists_norm_lt_of_ae; in the sup norm of $\mathbb{R}^\ell$ this gives $|t|_1 < 1$ Chapter15/GeneralPositionAssembly · SBLocalization.sum_abs_lt_one. *Step 5, the perturbation* $\tilde{\Lambda} = \Lambda_0 \oplus F_t$. It is structurable (Proposition 13.3.12). Over ∂X it equals Λ_0: a point of ∂X is not in the domain support of F_t, which lies in $U \setminus \partial X$. Its domain support lies in the union of the two, inside U. Its norm: with $m = h - N(\Lambda_0) > 0$ at x, $N(F_t)(x) \le |t|_1 m < m$, so $N(\tilde{\Lambda})(x) \le N(\Lambda_0)(x) + N(F_t)(x) < h(x)$, pointwise, without a uniform margin. It is in general position by the choice of t, hence transversal Chapter15/GeneralPositionAssembly · SBLocalization.isTransversal_of_isInGeneralPosition. □ Under the hypotheses of the relative statement the two steps give the relative statement Chapter15/RelativeReduction · SBLocalization.theorem_15_3_7_relative_of_hyp; the relative parametric transversality is proved (below), so the relative local families alone suffice Chapter15/RelativeParametric · SBLocalization.theorem_15_3_7_relative_of_local.

Readings. "Supported away from ∂X" is domain support in $U \setminus \partial X$ (∂X is closed and saturated). The text bounds the family by the norm of the perturbation without saying by what; the bound $N(\Lambda_t) \le |t|_1(h - N(\Lambda_0))$ is the one that keeps $N(\Lambda_0 \oplus \Lambda_t) < h$ for $|t|_1 < 1$ pointwise, and the parametric step needs only the weaker $|t|_1(1 - N(\Lambda_0))$. The text writes $\Lambda_t \oplus \Lambda_0$; the formalization adds in the other order, which changes nothing.

The relative parametric transversality (explicit) Chapter15/RelativeParametric · SBLocalization.hasParametricGeneralPositionRel. For X tame, f an sc-Fredholm section functor with tame germ data, (N, U) controlling compactness and Λ_0 an sc⁺-multisection with $N(\Lambda_0) \le 1$ and domain support in U, the relative parametric transversality holds. The compactness of $|S_f|$ is not used; that of $|\operatorname{supp}(\Lambda_0 \circ f)|$ comes from the control of compactness. The proof is that of the parametric transversality of Theorem 15.3.7 (§XV.25) with a branch s_a^0 of Λ_0 in place of the zero section, in four parts: one branch, the local step, the relative (15.2), and the assembly.

One branch of $\Lambda_0 \oplus \Lambda_t$. On a common open set O, local representations (s_a^0, σ_a^0) of Λ_0 and (s_i, σ_i) of Λ give the representation of $\Lambda_0 \oplus \Lambda$ by the sections $s_a^0 + s_i$ with the weights $\sigma_a^0 \sigma_i$, reindexed by a finite type (Definition 13.2.9 (3)) Chapter15/RelativeBranch · SBLocalization.isLocalRepOn_multisectionAdd: the sums are sc⁺ on O, the weights sum to $\sum_a \sigma_a^0 \sum_i \sigma_i = 1$, and the count formula is that of the sum of Part XIII Chapter13/MultisectionAlgebra · SBLocalization.multisectionAdd_eq_sum_of_isLocalRepOn. For a linear family the branch through s_a^0 and $\sum_j t_j s_{ij}$ is the slice at t of Part I's parametrized section on $\mathbb{R}^\ell \times O$,

$$F_{a,i}(t, y) = (f - s_a^0)|_O(y) + \sum_j t_j (-s_{ij})|_O(y),$$

that is, the slice at t is $(f - (s_a^0 + \sum_j t_j s_{ij}))|_O$ Chapter15/RelativeBranch · SBLocalization.paramSlice_branch_eq_rel, a fibrewise identity in W_y (the restricted sections being f plus (-1) times the section extended by zero off O).

Relative (15.1) gives Part I's conditions (i)–(ii) Chapter15/RelativeBranch · SBLocalization.isParamGP_restrictTo_of_onto_rel. Let c be a strong bundle chart of W with domain in O, centred at x ($c(x) = 0$), with $f(x) = s^0(x)$, T a presentation of its model quadrant, and assume that $(v, \tau) \mapsto (f - s^0)'(x)v + \sum_j \tau_j s_j(x)$ maps $T_x^R X \times \mathbb{R}^\ell$ onto W_x. Then in the transported chart of $W|_O$ the parametrized section F has Part I's properties (i)–(ii) of the proof of Theorem 5.3.10 Chapter5/GeneralPosition · StrongBundleChart.IsParamGP. The proof reads everything in the chart. The linearization at 0 of the principal part of $(f - s^0)|_O$ in the transported chart is the chart derivative $D((\widehat{f} -$

$\widehat{s}^0) \circ r)(0)$ Chapter15/LocalIFT · SBLocalization.scDeriv_restrictTo_subRestrict; the principal part of $-s_j$ at 0 is minus the chart image of $s_j(x)$ Chapter15/BranchChart · SBLocalization.principal_eq_fiberLin Chapter15/BranchChart · SBLocalization.principal_restrictTo_negRestrict; and the chart image of the intrinsic operator applied to v is the chart derivative applied to the chart vector of v Chapter15/BranchChart · SBLocalization.fiberLin_toIntr_subDeriv. So the hypothesis says: for every w there are $v \in T^R_x X$ and τ with $D(v) + \sum_j \tau_j \widehat{s}_j(0) = \widehat{w}$. (i), $F'(0,x)$ onto: given k with $(0,k) \in K$, write $k = \widehat{w}$ and take $u = v$ and $a = -\tau$, the sign coming from the $-s_j$. (ii), the kernel of $F'(0,x)$ is transversal to $\mathbb{R}^\ell \oplus T^R$: given a tangent vector w at 0, apply the hypothesis to the image $D(w)$; it gives $v \in T^R$ and τ with $D(v) + \sum_j \tau_j \widehat{s}_j(0) = D(w)$; then $u = w - v$ has $D(u) - \sum_j \tau_j \widehat{s}_j(0) = 0$, so (τ, u) is in the kernel, and $w - u = v \in T^R$. These are the two lines of linear algebra of the bridge of §XV.24, with s^0 for 0.

The parametrized branch is in general position Chapter15/RelativeBranch · SBLocalization.isGeneralPositionGerm_branchParam_rel. Let (s^0_a, σ^0_a) represent Λ_0 on O, $s^0_a(x) = f(x)$, and assume relative (15.1) at x for the sections s_j. Then $F_a(t,y) = (f - s^0_a)|_O + \sum_j t_j(-s_j)|_O$ is in general position at $(0,x)$ (Definition 5.3.9 on $\mathbb{R}^\ell \times O$). *Proof.* x is smooth, being a zero of $f - s^0_a$ Chapter15/Transversality · SBLocalization.mem_smoothSet_of_eq, so the tame germ data give a tame strong bundle chart centred at x; restrict it to O, and take a presentation T of its quadrant. With this chart and the local structure (s^0, σ^0) as local data, the intrinsic operator $(f - s^0_a)'(x)$ lies in the support of $T(f, \Lambda_0)(x)$ Chapter15/LinearizationIntrinsic · SBLocalization.linearization_eq Chapter15/Transversality · SBLocalization.mem_support_linSumIntr_iff, so relative (15.1) applies to it in this chart. The previous step gives (i)–(ii) in the transported chart; $(f - s^0_a)|_O$ is a tame sc-Fredholm section of $W|_O$ Chapter15/LocalScPlus · SBLocalization.isScFredholmSectionTame_subRestrict vanishing at x; and Part I's lemma that (i)–(ii) at a zero give general position of the parametrized section Chapter5/GeneralPosition · isGeneralPositionGerm_paramSection_of_isParamGP concludes.

The local step Chapter15/RelativeParametric · SBLocalization.exists_local_paramGP_rel. Let X be tame, Λ_0 an sc$^+$-multisection, Λ_t sc$^+$-multisections with relative (15.1) at x_0. Then there are an open $V \ni x_0$, $\delta > 0$ and a Lebesgue null set $C_V \subset \mathbb{R}^\ell$ such that $(f, \Lambda_0 \oplus \Lambda_t)$ is in general position at every $y \in V$ with $(\Lambda_0 \oplus \Lambda_t)(f(y)) > 0$, for $\|t\| < \delta$, $t \notin C_V$. *Proof.* Relative (15.1) provides a linear representation $\sum_j t_j s_{ij}$ of the family on O_1; take a representation (s^0_a, σ^0_a) of Λ_0 on O_2, its sections extended by zero, and $O = O_1 \cap O_2$; O is a tame M-polyfold, an open subset of a tame one. For every pair (a,i) there are an open $W_{a,i} \ni (0, x_0)$ in $\mathbb{R}^\ell \times O$ and a null set $C_{a,i}$ such that, for $(t,y) \in W_{a,i}$ with $f(y) = s^0_a(y) + \sum_j t_j s_{ij}(y)$ and $t \notin C_{a,i}$, the branch $(f - (s^0_a + \sum_j t_j s_{ij}))|_O$ is in Part I's general position at y. Two cases. If $f(x_0) = s^0_a(x_0)$, then $(0, x_0)$ is a zero of $F_{a,i}$, the slice at $t = 0$ being $f - s^0_a$ Chapter15/RelativeParametric · SBLocalization.sectionAdd_paramSec_zero, $F_{a,i}$ is in general position there by the previous lemma, and Part I's local Sard step, the local form of Theorem 5.3.10 without compactness Chapter15/LocalSlice · StrongBundle.exists_null_isGeneralPositionGerm_paramSlice_near, gives the neighbourhood and the null set; its slices are the branches. If $f(x_0) \neq s^0_a(x_0)$, the zero set of $F_{a,i}$, closed because $F_{a,i}$ is sc-smooth (Part I's Theorem 3.1.21) Chapter3/ParamPerturbationG · Polyfold.theorem_3_1_21_tame Chapter5/Transversality · isClosed_solutionSet, misses $(0, x_0)$; its complement is $W_{a,i}$ and $C_{a,i} = \emptyset$. The finitely many $W_{a,i}$ contain a product $B_\delta(0) \times V'$, and $C_V = \bigcup_{a,i} C_{a,i}$ is null. For $y \in V'$, $\|t\| < \delta$, $t \notin C_V$ and $(\Lambda_0 \oplus \Lambda_t)(f(y)) > 0$: y is at level 1; restrict a chart around y to O; the sum representation has the branches $s^0_a + \sum_j t_j s_{ij}$; each branch through $f(y)$ is in Part I's general position at y by the choice of $W_{a,i}$; and Part I's general position of the branches through $f(y)$ is Definition 15.3.5 at y Chapter15/GeneralPositionLocal · SBLocalization.isReducedOntoAtLevel_of_isGeneralPositionGerm (§XV.16).

Relative (15.2) Chapter15/RelativeParametric · SBLocalization.exists_pos_supp_rel_subset. If (N, U) controls

compactness, $N(\Lambda_0) \le 1$, the domain supports lie in U, $N(\Lambda_t) \le |t|_1(1-N(\Lambda_0))$, and V is a saturated open set containing $\operatorname{supp}(\Lambda_0 \circ f)$, then for some $\varepsilon > 0$ every t with $|t|_1 < \varepsilon$ has $\operatorname{supp}((\Lambda_0 \oplus \Lambda_t) \circ f) \subset V$. The text's (15.2) has S_f; relative to Λ_0 the support of $\Lambda_0 \circ f$ takes its place. *Proof*, by contradiction. Suppose there are t_n with $|t_n|_1 < 1/(n+1)$ and $x_n \notin V$ with $(\Lambda_0 \oplus \Lambda_{t_n})(f(x_n)) > 0$. For $|t|_1 \le 1$, $N(\Lambda_0 \oplus \Lambda_t) \le N(\Lambda_0) + |t|_1(1 - N(\Lambda_0)) \le 1$, so $x_n \in U$ and $N(f(x_n)) \le 1$ `Chapter15/ParametricGeneralPosition · SBLocalization.auxLe_of_pos`, using the sum of multisections (Definition 13.2.9) `Chapter13/MultisectionAlgebra · SBLocalization.definition_13_2_9`. The orbits $\pi(x_n)$ lie in the compact closure that the control of compactness provides; they have a cluster point $\pi(z)$. The object space is metrizable; along a decreasing basis B_k of neighbourhoods of z pick $n_k \ge k$ and $y_k \in B_k$ in the orbit of x_{n_k} (the orbit map is open, so $\pi(B_k)$ is a neighbourhood of $\pi(z)$ met infinitely often). Then $y_k \to z$, $y_k \notin V$ (V saturated), and $(\Lambda_0 \oplus \Lambda_{t_{n_k}})(f(y_k)) > 0$, since f and the sum are functors. Decompose $f(y_k) = a_k + b_k$ with $\Lambda_0(a_k) > 0$ and $\Lambda_{t_{n_k}}(b_k) > 0$ `Chapter15/RelativeParametric · SBLocalization.exists_of_multisectionAdd_pos_at` `Chapter15/ParamFamily · SBLocalization.exists_of_multisectionAdd_pos`; then $N(b_k) \le N(\Lambda_{t_{n_k}})(y_k) \le |t_{n_k}|_1 \le 1/(k+1)$. Take a local representation (s_i^0, σ_i^0) of Λ_0 on $O_2 \ni z$; for large k, $y_k \in O_2$ and $a_k = s_i^0(y_k)$ for some branch i; some i occurs infinitely often, and along that subsequence $(f - s_i^0)(y_k) = b_k$ `Chapter15/RelativeParametric · SBLocalization.subSec_eq_of_add`. The section $f - s_i^0$ is continuous on O_2, being a tame sc-Fredholm section of $W|_{O_2}$, so $(f - s_i^0)(y_k) \to (f - s_i^0)(z)$; and $b_k \to 0_z$, because the b_k lie in $W_{0,1}$, their base points converge to z and their norms to 0, which for an auxiliary norm forces convergence to the zero vector. Hence $f(z) = s_i^0(z)$, so $\Lambda_0(f(z)) > 0$ and $z \in V$; V being open, $y_k \in V$ for large k, a contradiction. The text's analogue for $\Lambda_0 = 0$ is the statement (15.2) of §XV.25; the new point is the branch of Λ_0 met infinitely often.

The assembly. Let $S = \operatorname{supp}(\Lambda_0 \circ f)$. Every $z \in S$ is at level 1 (§XV.20), so the local step applies at z and gives V_z, δ_z, C_z. $|S|$ is compact (Step 2 above); finitely many $\pi(V_z)$, $z \in T$, cover it. Let V_s be the saturation of $\bigcup_{z \in T} V_z$, open and saturated, containing S. Relative (15.2) gives ε_0 with $\operatorname{supp}((\Lambda_0 \oplus \Lambda_t) \circ f) \subset V_s$ for $|t|_1 < \varepsilon_0$. Choose $\varepsilon > 0$ so that $\|t\| < \varepsilon$ implies $\|t\| < \delta_z$ for $z \in T$ and $|t|_1 < \varepsilon_0$. The union of the C_z, $z \in T$, is null. For t off it with $\|t\| < \varepsilon$, and x in the support of $(\Lambda_0 \oplus \Lambda_t) \circ f$: $x \in V_s$, so there are $y \in V_z$ for some $z \in T$ and a morphism $\varphi : y \to x$; the support is saturated, so y is in it; general position holds at y by the local step; and general position at a point is carried along morphisms `Chapter15/ParametricGeneralPosition · SBLocalization.isInGeneralPositionAt_of_mor` (§XV.25). Pointwise general position everywhere on the support is general position `Chapter15/GeneralPositionLocal · SBLocalization.isInGeneralPosition_iff_forall_at`. □ The text discusses a countable cover and then remarks that a finite one suffices; the formal proof uses the finite cover directly, as in §XV.25.

What remains: the relative local families (gap G.178). Everything in steps (c)–(d) is proved except the proposition `Chapter15/ChargedExtensionFibres · SBLocalization.relative_local_families_statement` that every point of $\operatorname{supp}(\Lambda_0 \circ f)$ has a relative family with domain support in $U \setminus \partial X$ and bound $|t|_1(h - N(\Lambda_0))$, under the hypotheses of the relative statement. It splits in two `Chapter15/RelativeReduction · SBLocalization.hasLocalGPFamiliesRel_of_boundary`: at the points of $\operatorname{supp}(\Lambda_0 \circ f) \cap \partial X$ the empty family suffices as soon as (f, Λ_0) is reducedly onto at the support points of a saturated open neighbourhood, by the empty family of a set on which this holds; at the other points a relative family is needed. The first is the openness of general position near the boundary part of the support, which the text gets from the implicit function theorem (the neighbourhoods $Q(x)$ of its step (c)); the second is the text's "for $x \in U \setminus Q$ … we note that $d_X(x) = 0$ and we can argue as in Theorem 15.3.7": seeds at interior support points as in §XV.23, now making all the operators $(f - s_a^0)'(x)$ of $T(f, \Lambda_0)(x)$ onto at once, with domain support in a small neighbourhood that avoids ∂X. What each needs, with estimates, is in §XV.38. Wit-

nesses of the two relative steps: on $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$ every pair is in general position, so the empty family covers everything Chapter15/RelativeReduction · SBLocalization.hasLocalGPFamiliesRel_epSEP_zero Chapter15/RelativeReduction · SBLocalization.hasParametricGeneralPositionRel_epSEP_zero, and the relative statement holds there from them Chapter15/RelativeReduction · SBLocalization.theorem_15_3_7_relative_statement_epSEP_zero_of_hyp Chapter15/RelativeParametric · SBLocalization.theorem_15_3_7_relative_statement_epSEP_zero_of_local; these witnesses have no boundary and zero fibres, so they are **weak**.

XV.30 The cylinder $[0,1]^n \times X$, and $d_X \equiv 0$ implies tame (prerequisites for Corollary 15.3.10)

Corollary 15.3.10 (p. 699) and its proof work on "the tame ep-groupoid $[0,1] \times X$" with the pulled-back strong bundle $\widetilde{W} \to [0,1] \times X$, whose fibre over (t,x) is W_x, and the section $\tilde{f}(t,x) = (t, f(x))$. The text takes all of this for granted, and it assumes $d_X \equiv 0$ where Theorems 15.3.7 and 15.3.9, which it applies, ask for a tame X. This subsection builds the cylinder and proves the two facts the corollary uses silently: that the cylinder is a tame ep-groupoid with the expected boundary, orbit space and bundle, and that $d_X \equiv 0$ makes X tame.

The cube instead of the interval. The formalization builds $[0,1]^n \times X$ for every n, with Part I's cube $[0,1]^n$ (the M-polyfold of maps $\{1,\dots,n\} \to [0,1]$); the text's $[0,1] \times X$ is $n = 1$. The reason is that Part I's parametrized Fredholm theory, which gives the sc-Fredholm property of $\tilde{f}$, is stated for the cube. Where the boundary or the time coordinate matters, $n = 1$ is fixed.

The ep-groupoid (extra) Chapter15/CubeEp · EpGroupoid.cubeProd. $[0,1]^n \times X$ is the product (§XV.19) of the trivial ep-groupoid of the cube, whose only morphisms are identities, with X: objects (q,x), morphisms (q,φ), with source $(q, s(\varphi))$ and target $(q, t(\varphi))$. Two functors connect it with X. The projection $(q,x) \mapsto x$, $(q,\varphi) \mapsto \varphi$ is the second projection of the product Chapter15/CubeEp · EpGroupoid.cubeProj. The inclusion $i_q : x \mapsto (q,x)$, $\varphi \mapsto (q,\varphi)$ at a point q of the cube Chapter15/CubeEp · EpGroupoid.cubeIncl is sc-smooth because a constant map with a smooth value is sc-smooth Chapter15/CubeEp · MPolyfold.isScSmoothMap_const_of_mem_smoothSet_poly and every point of the finite-dimensional cube is smooth Chapter15/CubeEp · cubePolyfold_mem_smoothSet; and $\mathrm{pr} \circ i_q = \mathrm{id}$ Chapter15/CubeEp · EpGroupoid.cubeProj_comp_cubeIncl.

Tameness and the boundary. If X is tame, so is $[0,1]^n \times X$ Chapter15/CubeEp · EpGroupoid.isTame_cubeProd, by Part I's tameness of products with the cube Chapter6/CubeSections · prod_cube_isTame. The degeneracy index is additive, $d(q,x) = \#\{i : q_i \in \{0,1\}\} + d_X(x)$ Chapter15/CubeEp · EpGroupoid.degIndex_cubeProd: the first term is the degeneracy index of the cube at q, and the sum is Part I's degeneracy index of a product of tame M-polyfolds. For $n = 1$ and $d_X \equiv 0$ the count runs over a one-element index set, so $d(t,x) = 1$ if $t \in \{0,1\}$ and $d(t,x) = 0$ otherwise Chapter15/CubeEp · EpGroupoid.degIndex_cubeProd_one_of_degIndex_eq_zero. The boundary is the set of points of positive degeneracy index, so $\partial([0,1] \times X) = \{0,1\} \times X$ Chapter15/RegularPerturbations · SBLocalization.mem_boundary_cubeSEP_iff. This is the fact behind "Λ over $i = 0,1$": the boundary data of Theorem 15.3.9 on the cylinder are data over the two ends.

Isomorphism classes and the orbit space. Since the cube contributes only identities, (q,x) and (q',x') are isomorphic iff $q = q'$ and x, x' are isomorphic Chapter15/CubeEp · EpGroupoid.cubeProd_π_eq_π_iff; hence $S \times U$ is saturated whenever U is Chapter15/CubeEp · EpGroupoid.isSaturated_prod_cubeProd. The map $(q, |x|) \mapsto |(q,x)|$ from $[0,1]^n \times |X|$ to the orbit space of the cylinder is well defined by the same criterion Chapter15/CubeEp · EpGroupoid.cubeOrbitMap. It is continuous Chapter15/CubeEp · EpGroupoid.continuous_cubeOrbitMap: $\mathrm{id} \times \pi$ is an open quotient map (the orbit map of X is open, Proposition 7.1.8), and

composed with it the map is the orbit map of the cylinder, which is continuous. It carries $[0,1]^n \times |A|$ onto $|[0,1]^n \times A|$ `Chapter15/CubeEp · EpGroupoid.image_π_cubeProd`, so $|[0,1]^n \times A|$ is compact when $|A|$ is `Chapter15/CubeEp · EpGroupoid.isCompact_image_π_cubeProd`. More is true. The map is injective `Chapter15/Cylinder · EpGroupoid.injective_cubeOrbitMap` (the isomorphism criterion again), surjective `Chapter15/Cylinder · EpGroupoid.surjective_cubeOrbitMap` (every orbit has a representative (q,x)), and open `Chapter15/Cylinder · EpGroupoid.isOpenMap_cubeOrbitMap`: the image of an open $O \subset [0,1]^n \times |X|$ is the image under the orbit map of the cylinder of the open set $(\mathrm{id} \times \pi)^{-1}(O)$, and the orbit map of the cylinder is open by Proposition 7.1.8. So it is a homeomorphism $[0,1]^n \times |X| \cong |[0,1]^n \times X|$ `Chapter15/Cylinder · EpGroupoid.cubeOrbitHomeomorph`. A product of a compact space with a paracompact space is paracompact, and paracompactness is carried by homeomorphisms; so the orbit space of the cylinder is paracompact when $|X|$ is `Chapter15/Cylinder · EpGroupoid.hasParacompactOrbitSpace_cubeProd`. This is the hypothesis "paracompact orbit space" of Theorem 15.3.9 on the cylinder, derived from the corollary's own hypothesis on $|X|$.

Bump functions. If X admits sc-smooth bump functions (Definition 12.3.1, read pointwise), so does $[0,1]^n \times X$ `Chapter15/CubeEp · EpGroupoid.admitsBumpFunctionsPointwise_cubeProd`: Theorem 12.3.2 (1) passes between the ep-groupoid and its object M-polyfold, and Part I proves bump functions on products with the cube `Chapter6/CubeSections · admitsBumpFunctions_prod_cube`.

The bundle and the section (narrower). $\widetilde{W}$ is the pull-back of W along the projection functor `Chapter15/CubeEp · SEP.cubeSEP`, Chapter 10's pull-back of a strong bundle over an ep-groupoid along a functor. A point of $\widetilde{W}$ is a pair $((q,x),w)$ with $w \in W_x$ `Chapter15/CubeEp · SEP.cubeVal`, and the morphism (q,φ) acts by $\tilde{\mu}((q,\varphi),((q,x),w)) = ((q,t(\varphi)),\mu(\varphi,w))$ `Chapter15/CubeLift · SBLocalization.cubeVal_fibAct`. The section is $\tilde{f}(q,x) = ((q,x),f(x))$ `Chapter15/CubeEp · SEP.cubeLiftEp`, a section of $\widetilde{W}$ `Chapter15/CubeEp · SEP.isSection_cubeLiftEp`. The text writes $\tilde{f}(t,x) = (t,f(x))$ in the statement and $\tilde{f}(t,x) = f(x)$ in the proof; both mean this section.

It is a functor `Chapter15/CubeEp · SEP.isFunctorialSection_cubeLiftEp`: at a morphism (q,φ) the identity $\tilde{f}(t(q,\varphi)) = \tilde{\mu}((q,\varphi),\tilde{f}(s(q,\varphi)))$ has first component $(q,t(\varphi))$ on both sides, and its second component is $f(t(\varphi)) = \mu(\varphi,f(s(\varphi)))$, the functor property of f. *It is sc-smooth* `Chapter15/CubeEp · SEP.isScSmoothSectionFunctor_cubeLiftEp`, by Part I's pull-back of sc-smooth sections along the sc-smooth projection. *It is sc-Fredholm when f has Part I's tame germ data* `Chapter15/CubeEp · SEP.isScFredholmSectionFunctor_cubeLiftEp`: the germ of $\tilde{f}$ at (q,x) is the germ of f at x with the cube coordinates as parameters, and Part I proves that this parametrized germ has tame germ data again `Chapter6/CubeFredholm · StrongBundle.IsScFredholmSectionTame.paramCube`, which gives the sc-Fredholm property; the tame germ data of $\tilde{f}$ are recorded separately, for the theorems that need them on the cylinder `Chapter15/RegularPerturbations · SBLocalization.isScFredholmSectionTame_cubeLiftEp`. *Its solution set* is $S_{\tilde{f}} = [0,1]^n \times S_f$ `Chapter15/CubeEp · SEP.solutionSet_cubeLiftEp`, since the second component of $\tilde{f}(q,x)$ is $f(x)$ and the zero of $\widetilde{W}_{(q,x)}$ is $((q,x),0_x)$; so $|S_{\tilde{f}}|$ is compact when $|S_f|$ is `Chapter15/CubeEp · SEP.hasCompactSolutionSetEp_cubeLiftEp`, by the compactness of $|[0,1]^n \times A|$ above.

The added hypothesis. The row is narrower only through the tame germ data of f, Part I's hypothesis for its parametrized Fredholm theory (Part I's untamed parametrized case is not formalized; with the 2021 untamed notion Part I's Theorem 3.6.8 does not hold as we read it, Part III). It is inherited, as in all of §15.2 (§XV.10), not new; its witness is the zero section of $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$ with its graph section's tame germ data `Chapter15/InteriorPerturbationWitness · SBLocalization.theorem_15_2_2_hyp_witness` `Chapter3/NonVacuityG · isScFredholmSectionTame_graphSection`. The rest (tameness, boundary, orbit space, bump functions, compact solution set) holds as the text uses it.

$d_X \equiv 0$ **implies tame** (extra) `Chapter5/DegeneracyZeroTame · EpGroupoid.isTame_of_degIndex_eq_zero`. *Statement.* An ep-groupoid whose degeneracy index vanishes at every object is tame; it is the statement for its object M-polyfold `Chapter5/DegeneracyZeroTame · MPolyfold.isTame_of_degIndex_eq_zero`. Corollary 15.3.10 assumes $d_X \equiv 0$ and applies Theorems 15.3.7 and 15.3.9, which are stated for tame X; the text passes from one to the other without comment.

Proof, the local step `Chapter5/DegeneracyZeroTame · isTameRetract_inter_of_degIndex_eq_zero_ty`. Let $r : U \to U$ be an sc-smooth retraction of a partial quadrant $C \subset E$, presented by an sc-isomorphism $T : E \cong \mathbb{R}^k \times W'$ with $C = T^{-1}([0,\infty)^k \times W')$, and let W be open with $d_C = 0$ on $r(U) \cap W$. The claim is that $r(U) \cap W$ is a tame retract (Definition 2.5.2). (i) For $z \in C$, $d_C(z) = 0$ iff all k half-line coordinates of $T(z)$ are positive `Chapter5/DegeneracyZeroTame · degIndexWith_eq_zero_iff_ty` `Chapter5/DegeneracyZeroTame · degIndex_eq_zero_iff_pos_ty`, and the set D of such z is open `Chapter5/DegeneracyZeroTame · isOpen_setOf_pos_coord_ty`, a finite intersection of open half-spaces. (ii) Restrict r to $U' = U \cap r^{-1}(W) \cap D$. This is still an sc-smooth retraction: U' is relatively open, r maps U' into $r(U) \cap W$, where $d_C = 0$, hence into D, and $r \circ r = r$. Its retract is $r(U) \cap W$: a point of $r(U) \cap W$ is fixed by r and lies in D. (iii) Definition 2.5.2 (1), $d_C(r(x)) = d_C(x)$ on U', holds because both sides are 0 there. (iv) Definition 2.5.2 (2) asks, at a smooth point x of the retract, for an sc-complement of T_xO inside the minimal subspace E_x of E spanned by the directions in which no vanishing coordinate is tied down. Since no half-line coordinate of x vanishes, $E_x = E$, and the range of $Dr(x)$ is sc-complemented in E by $\ker Dr(x)$, Part I's sc-splitting of the range of the derivative of a retraction. Hence the restricted retract is tame.

Proof, the M-polyfold. At a point x take a chart φ whose degeneracy index at x attains $d_X(x) = 0$ (Definition 2.4.1 takes a minimum over charts, and it is attained). The points of its domain with chart degeneracy index 0 form an open set s, by the upper semicontinuity of the chart degeneracy index; the restriction of φ to s is again a chart of the structure, and its image is $r(U) \cap W$ for an open W. On it $d_C = 0$, so it is a tame retract by the local step, and the M-polyfold is tame by Part I's criterion that every point lie in a chart on a tame retract `Chapter2/TameFaces · MPolyfold.isTame_of_forall_exists_chart`. The ep-groupoid is tame when its object M-polyfold is. Gap G.183 is closed.

XV.31 Corollary 15.3.10 (1) and (2) (2017: Corollary 15.1 (1), (2))

The setting. Corollary 15.3.10 (p. 699) assumes a strong bundle over an ep-groupoid with $d_X \equiv 0$ and paracompact orbit space $|X|$, and an sc-Fredholm section functor f with $|S_f|$ compact. Part (1) produces a perturbation for one controlling pair, (2) an auxiliary norm on the cylinder that interpolates two controlling pairs, (3) a perturbation on the cylinder that interpolates two perturbations (§§XV.32–XV.33).

Definition: regular perturbations `Chapter15/RegularPerturbations · SBLocalization.IsRegularPerturbation`. (N, U, Λ) is a structurable regular perturbation of f if (N, U) controls the compactness of f (Definition 15.3.1, §XV.17), Λ is structurable (Definition 13.3.6, Part XIII), its domain support lies in U, $N(\Lambda)(x) < 1$ for all x, and (f, Λ) is transversal (Definition 15.2.1, §XV.12). This is the text's definition in (1): "$T(f,\Lambda)(x)$ onto for all $x \in \operatorname{supp}(\Lambda \circ f)$" is transversality, and the clauses about Θ are a consequence, not part of the definition.

Corollary 15.3.10 (1) (narrower) `Chapter15/Cylinder · SBLocalization.corollary_15_3_10_1_ty`. *Statement.* Let $d_X \equiv 0$, $|X|$ paracompact, X admit sc-smooth bump functions, f be an sc-Fredholm section functor with Part I's tame germ data and $|S_f|$ compact, and (N, U) control the compactness of f. Given the statement of Theorem 15.3.7 for the bundle, there is a Λ such that (N, U, Λ) is a structurable reg-

ular perturbation, (f, Λ) is in general position (Definition 15.3.5), and $\Theta = \Lambda \circ f$ is a branched ep⁺-subgroupoid with compact $|\operatorname{supp}\Theta|$. The statement of Theorem 15.3.7 holds for every bundle whose orbit space is paracompact `Chapter15/GeneralPositionGoodSystem · SBLocalization.theorem_15_3_7_of_paracompact` (§XV.26), which the corollary assumes; so the hypothesis is discharged under the corollary's own assumptions. The two declarations compose; the composite is not stated as one declaration.

Proof. (i) *Tameness.* X is tame because $d_X \equiv 0$ (§XV.30). (ii) *Theorem 15.3.7 with $h \equiv 1$.* The constant function 1 is continuous, constant along morphisms and satisfies $0 < h \leq 1$; the statement of Theorem 15.3.7 (§XV.21) then gives a structurable Λ with $N(\Lambda) < 1$, domain support in U, (f, Λ) transversal and in general position. These are the clauses of a regular perturbation, with general position in addition. (iii) *The "in particular".* With $N(\Lambda) \leq 1$, domain support in U and general position, Theorem 15.3.7's "in particular" `Chapter15/GeneralPositionBranched · SBLocalization.theorem_15_3_7_in_particular_hyp` (§XV.21) makes Θ a branched ep⁺-subgroupoid with compact support; its tame form `Chapter15/TameBranched · SBLocalization.theorem_15_3_7_in_particular_tame_hyp` gives the text's "tame branched". (iv) *Where the hypotheses enter.* $d_X \equiv 0$ is used only for (i), and paracompactness only through Theorem 15.3.7's structurable addendum, which needs a good system, supplied by Theorem 13.1.8 for paracompact $|X|$ (§XV.26). The text's proof says "a special case of Theorem 15.3.7"; the special case is $h \equiv 1$.

Intermediate form. The same conclusion with "X tame" as an extra hypothesis in place of its derivation `Chapter15/RegularPerturbations · SBLocalization.corollary_15_3_10_1_hyp`; the final form calls it with the tameness of §XV.30.

Added hypotheses. Sc-smooth bump functions, which Theorem 15.3.7 needs and the corollary does not state; Remark 15.3.2 says that the theory needs them. And the tame germ data of f, inherited from §15.2 (§XV.10). Neither is derived from the corollary's statement; they hold together with the corollary's own hypotheses on the example of §XV.13 over $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$ `Chapter15/InteriorPerturbationWitness · SBLocalization.theorem_15_2_2_hyp_witness`, where $d_X \equiv 0$ and $|X| = \mathbb{R}^n$ is paracompact; there the zero section with the zero multisection is a regular perturbation, a degenerate one (zero fibres).

Corollary 15.3.10 (2) (same) `Chapter15/CubeAuxNorm · SEP.corollary_15_3_10_2`. *Statement.* If (N^0, U^0) and (N^1, U^1) control the compactness of f, there are an auxiliary norm $\widetilde{N}$ of $\widetilde{W} \to [0,1] \times X$ and a saturated open $\widetilde{U} \supset S_{\tilde{f}}$ such that $(\widetilde{N}, \widetilde{U})$ controls the compactness of $\tilde{f}$ and restricts to (N^i, U^i) over $t = i$. The text states (2) for regular perturbations (N^i, U^i, Λ^i); the Λ^i play no role in it, and only the control of compactness is assumed. The text does not give $\widetilde{N}$; its proof pulls back a single N, which is the first step below. The formalization proves both.

The proof's step: one pair, pulled back. $\widetilde{N}(q, x, h) = N(h)$ `Chapter15/CubeAuxNorm · SEP.cubeAuxNorm` is Part I's pull-back of an auxiliary norm along a map of the base `Chapter5/CylinderPerturbation2021 · StrongBundle.pullbackAuxNorm`; its value at a point of $\widetilde{W}_{0,1}$ is N of the W-component `Chapter15/CubeAuxNorm · SEP.cubeAuxNorm_eq`. It is an auxiliary norm of the strong bundle $\widetilde{W}$ (Definition 5.1.1) `Chapter15/CubeAuxNorm · SEP.isAuxNorm_cubeAuxNorm'`, by Part I's lemma that pull-backs of auxiliary norms are auxiliary norms `Chapter5/CylinderPerturbation2021 · StrongBundle.IsAuxNorm.pullback`. It is invariant under $\tilde{\mu}$ (Definition 8.3.5 (3)) `Chapter15/CubeAuxNorm · SEP.isAuxNorm_cubeAuxNorm`: if $h = \tilde{\mu}((q, \varphi), k)$, then the W-component of h is $\mu(\varphi, k_2)$ and the cube coordinate is unchanged `Chapter15/CubeAuxNorm · SEP.cubeVal_μ`, so $\widetilde{N}(h) = N(\mu(\varphi, k_2)) = N(k_2) = \widetilde{N}(k)$ by the invariance of N. At the values of $\tilde{f}$, "$\widetilde{N}(\tilde{f}(q, x)) \leq r$" is "$N(f(x)) \leq r$" `Chapter15/CubeAuxNorm · SEP.auxLe_cubeAuxNorm_iff`. Then $(\widetilde{N}, [0,1]^n \times U)$ controls the compactness of $\tilde{f}$ whenever (N, U) controls that of f `Chapter15/CubeAuxNorm · SEP.controlsCompactness_cube`: $[0,1]^n \times U$ is open, saturated

(§XV.30) and contains $S_{\tilde f} = [0,1]^n \times S_f$; and its sublevel set $\{z \in [0,1]^n \times U : \widetilde N(\tilde f(z)) \le 1\}$ is $[0,1]^n$ times the sublevel set S of (N, U). The orbit set of $[0,1]^n \times S$ lies in the image of $[0,1]^n \times \mathrm{cl}\,|S|$ under the continuous map $(q, |x|) \mapsto |(q, x)|$, a compact set, so its closure is compact `Chapter15/CubeAuxNorm · SEP.isCompact_closure_image_π_cube`.

The weights. $\alpha(s) = \min(1, 3(1-s))$ `Chapter15/CubeAuxNorm · SEP.cubeWeight₀` and $\beta(s) = \min(1, 3s)$ `Chapter15/CubeAuxNorm · SEP.cubeWeight₁` are continuous and non-negative on $[0,1]$, $\alpha = 1$ on $[0, \frac{2}{3}]$, $\beta = 1$ on $[\frac{1}{3}, 1]$, $\alpha(1) = 0$, $\beta(0) = 0$, and at every s one of them is positive `Chapter15/CubeAuxNorm · SEP.cubeWeight_pos` (for $s \le \frac{2}{3}$, $\alpha(s) = 1$; otherwise $\beta(s) = 1$). With the time coordinate $t(w)$ of a point of $\widetilde W_{0,1}$ `Chapter15/CubeAuxNorm · SEP.cubeTime`, a continuous function, the interpolated norm is

$$\widetilde N(w) = \max\left(\alpha(t(w))\,\widetilde N^0(w),\ \beta(t(w))\,\widetilde N^1(w)\right)$$

`Chapter15/CubeAuxNorm · SEP.interpAuxNorm`, with $\widetilde N^i$ the pull-back of N^i, and the interpolated set is $\widetilde U = ([0, \frac{2}{3}) \times U^0) \cup ((\frac{1}{3}, 1] \times U^1)$ `Chapter15/CubeAuxNorm · SEP.interpSet`.

Step 1, a lemma on maxima. For auxiliary norms N_0, N_1 of a strong bundle and constants $a, b \ge 0$, not both 0, $\max(aN_0, bN_1)$ is an auxiliary norm `Chapter15/CubeAuxNorm · StrongBundle.isAuxNorm_max_mul`. If both are positive, Part I's lemmas that positive multiples and maxima of auxiliary norms are auxiliary norms apply; if $b = 0$, the maximum is aN_0, since $aN_0 \ge 0$, and symmetrically for $a = 0$.

Step 2, $\widetilde N$ is an auxiliary norm of $(\widetilde W, \tilde\mu)$ `Chapter15/CubeAuxNorm · SEP.isAuxNorm_interpAuxNorm`. Definition 5.1.1 has three conditions and Definition 8.3.5 adds the invariance. (0) Continuity on $\widetilde W_{0,1}$: products and maxima of continuous functions. (1) On each fibre a complete norm: on the fibre over z the time is the constant $t(z)$ `Chapter15/CubeAuxNorm · SEP.cubeTime_toOne`, so there $\widetilde N$ agrees with $\max(\alpha(t(z))\widetilde N^0, \beta(t(z))\widetilde N^1)$ for constants, which is a complete fibre norm by Step 1; completeness of a fibre norm depends only on the values on that fibre `Chapter15/CubeAuxNorm · StrongBundle.IsCompleteFiberNorm.congr`. (2) The convergence condition, that $w_k \in \widetilde W_{0,1}$ with $\widetilde P(w_k) \to z$ and $\widetilde N(w_k) \to 0$ converge to 0_z. Let t_0 be the time of z; one of $\alpha(t_0)$, $\beta(t_0)$ is positive, say $\alpha(t_0)$. By continuity $\alpha(t(w_k)) > \alpha(t_0)/2$ for large k, so $\widetilde N^0(w_k) \le (2/\alpha(t_0))\,\widetilde N(w_k) \to 0$, and condition (2) for $\widetilde N^0$ gives $w_k \to 0_z$; symmetrically if $\beta(t_0) > 0$. (3) Invariance: both $\widetilde N^i$ are invariant, and $\tilde\mu$ does not change the time (the same lemma on the cube coordinate as above).

Step 3, the restrictions. Over $t = 0$, $\alpha = 1$ and $\beta = 0$, so $\widetilde N = \widetilde N^0$ `Chapter15/CubeAuxNorm · SEP.interpAuxNorm_of_cubeTime_eq_zero`, and $(0, x) \in \widetilde U$ iff $x \in U^0$ `Chapter15/CubeAuxNorm · SEP.mem_interpSet_zero`; over $t = 1$, $\widetilde N = \widetilde N^1$ `Chapter15/CubeAuxNorm · SEP.interpAuxNorm_of_cubeTime_eq_one` and $(1, x) \in \widetilde U$ iff $x \in U^1$ `Chapter15/CubeAuxNorm · SEP.mem_interpSet_one`. This is "restricts over $i = 0, 1$ to N^i, U^i".

Step 4, $(\widetilde N, \widetilde U)$ controls the compactness of $\tilde f$. $\widetilde U$ is open, a union of two products of open sets. It is saturated: each piece is a product of a set of times with a saturated set (§XV.30), and images and preimages under the orbit map commute with unions. It contains $S_{\tilde f} = [0,1] \times S_f$: a point (t, x) with $x \in S_f$ lies in the first piece if $t < \frac{2}{3}$, since $S_f \subset U^0$, and in the second otherwise, since then $t > \frac{1}{3}$ and $S_f \subset U^1$. For the compactness, let $(t, x) \in \widetilde U$ with $\widetilde N(\tilde f(t, x)) \le 1$; the value $f(x)$ then lies in $W_{0,1}$, the level of the pull-back being that of W. If (t, x) is in the first piece, $\alpha(t) = 1$, so $N^0(f(x)) \le \widetilde N(\tilde f(t, x)) \le 1$ and x lies in the sublevel set S_0 of (N^0, U^0); in the second piece, x lies in the sublevel set S_1 of (N^1, U^1). So the sublevel set of $(\widetilde N, \widetilde U)$ lies in $([0,1] \times S_0) \cup ([0,1] \times S_1)$, whose orbit set has compact closure, by the pulled-back step applied to each piece. A closed subset of a compact set is compact.

Reading. The text's (2) asks for one pair restricting to the two given ones; it does not say how. The

interpolation is ours; any partition of the time interval into two overlapping pieces works, and the margin between $\frac{1}{3}$ and $\frac{2}{3}$ makes $\widetilde{U}$ open while each end sees only one of the two pairs. With §XV.30 ($\tilde{f}$ sc-Fredholm with compact solution set, under the inherited tame germ data), all of (2) is covered.

XV.32 Corollary 15.3.10 (3) (2017: Corollary 15.1 (3)): the glued boundary data and the partitions of unity of the cylinder

The proof of (3) (pp. 699–700) applies Theorem 15.3.9 on $[0,1]\times X$ to the multisection over $\partial([0,1]\times X) = \{0,1\}\times X$ that is Λ^i over $\{i\}\times X$, and concludes from its output. Theorem 15.3.9 in its charged form (§XV.27) asks, of the space, that it be tame with paracompact orbit space, sc-smooth partitions of unity and tame strong bundle charts at every object; and of the boundary data, that they be structurable over the boundary (Definition 14.1.7), charge every boundary fibre, have boundary domain support in $\widetilde{U}$, satisfy $\widetilde{N}(\Lambda) < h$ on the boundary, and satisfy the face condition. The text checks none of this explicitly. This subsection proves what can be proved about these hypotheses: tameness and paracompactness were done in §XV.30; here are the glued data with their values, support, norm and charge, the partitions of unity of the cylinder, and the structurability of the glued data up to one analytic statement.

The glued data `Chapter15/CylinderGlue · SBLocalization.cubeGlue`. $\Lambda_\partial(w) = \Lambda^1(w_2)$ if the time of w is 1, and $\Lambda^0(w_2)$ otherwise, w_2 being the W-component; so $\Lambda_\partial = \Lambda^0$ over $t = 0$ `Chapter15/CylinderGlue · SBLocalization.cubeGlue_of_zero` and Λ^1 over $t = 1$ `Chapter15/CylinderGlue · SBLocalization.cubeGlue_of_one`. The values at times strictly between 0 and 1 are irrelevant: Theorem 15.3.9 looks at its boundary data only over $\partial([0,1]\times X)$, and Λ there is a function on all of W of which only these values enter (§XV.27).

Boundary domain support `Chapter15/CylinderGlue · SBLocalization.boundaryDomSupp_cubeGlue_subset`. If the domain support of Λ^i lies in U^i, the boundary domain support of Λ_∂, the closure of the set of boundary points z over which some nonzero w has positive weight, lies in $\widetilde{U}$. *Proof.* Let z be such a point, $w \neq 0_z$ with $\Lambda_\partial(w) > 0$. By §XV.30, z has time 0 or 1; say 0. Then $\Lambda^0(w_2) > 0$ and $w_2 \neq 0$ in W_{z_2}, since w and $((z, 0_{z_2}))$ differ only in the W-component `Chapter15/CylinderGlue · SBLocalization.cubeVal_snd_ne_fiberZero`; so z_2 lies in the domain support of Λ^0. Hence the set lies in $(\{0\}\times\text{dom-supp }\Lambda^0)\cup(\{1\}\times\text{dom-supp }\Lambda^1)$, which is closed, so its closure does too; and a point of $\{i\}\times\text{dom-supp }\Lambda^i$ lies in $\widetilde{U}$ by the restriction of $\widetilde{U}$ over $t = i$ (§XV.31).

The norm on the boundary. $\widetilde{N}(\Lambda_\partial)(0,x) \le N^0(\Lambda^0)(x)$ `Chapter15/CylinderGlue · SBLocalization.pointwiseNorm_cubeGlue_le_zero` and $\widetilde{N}(\Lambda_\partial)(1,x) \le N^1(\Lambda^1)(x)$ `Chapter15/CylinderGlue · SBLocalization.pointwiseNorm_cubeGlue_le_one`. *Proof.* $N(\Lambda)(x)$ is the supremum of the norms of the points of the fibre over x with positive weight (Definition 13.2.3). A point w over $(0,x)$ with $\Lambda_\partial(w) > 0$ has W-component w_2 over x with $\Lambda^0(w_2) > 0$, and its norm is at most that of w_2 `Chapter15/CylinderGlue · SBLocalization.normW_interpAuxNorm_le`: on level 1, $\widetilde{N} = \widetilde{N}^0$ over $t = 0$ and $\widetilde{N}^0(w) = N^0(w_2)$; off level 1 both sides are the convention value. For an sc⁺-multisection the supremum is attained, so it is at least $N^0(w_2)$. Hence $\widetilde{N}(\Lambda_\partial) < 1$ on the boundary when $N^i(\Lambda^i) < 1$, which holds for regular perturbations.

The glued data charge the boundary. *An sc⁺-multisection charges every fibre* `Chapter15/ChargedExtensionCylinder · SBLocalization.exists_ne_zero_of_isScPlusMultisection`: near x it has a local representation by k sections with positive weights summing to 1, so $k > 0$; the first section gives $w = s_0(x)$ over x, and $\Lambda(w)$, the sum of the weights of the sections through w, is at least $\sigma_0 > 0$. So the glued data charge $\partial([0,1]\times X)$ `Chapter15/ChargedExtensionCylinder · SBLocalization.chargesBoundary_`

cubeGlue in the sense of Part XIV's charging condition Chapter14/EmptyIndex · SBLocalization.ChargesBoundary: at a boundary point (i, x) take $((i, x), v)$ with $\Lambda^i(v) \neq 0$. This is the hypothesis that the charged form of Theorem 15.3.9 adds (§XV.27), discharged for the cylinder.

Partitions of unity on $[0, 1] \times X$ (explicit). Theorem 15.3.9 asks for sc-smooth partitions of unity on the M-polyfold of objects; the text does not say why the cylinder has them. *Step 1, from Urysohn functions to partitions of unity* Chapter5/CubePartitions · admitsScPartitionsOfUnity_of_urysohn. If any two disjoint closed sets of an M-polyfold are separated by an sc-smooth function with values in $[0, 1]$, the M-polyfold admits sc-smooth partitions of unity: this is the second half of the proof of Theorem 5.5.10. Given an open cover, a bump covering subordinate to it by such functions f_i exists by a general construction in paracompact spaces (Mathlib's subordinate bump coverings with functions from a prescribed class), and $\rho_i = f_i \prod_{j<i}(1 - f_j)$ is the partition of unity; locally only finitely many factors are nontrivial, so each ρ_i is locally a finite product of sc-smooth real functions, hence sc-smooth.

Step 2, a local separation. Let s, t be disjoint closed sets of $[0, 1]^n \times X$ and $x \in X$. The slices $S = \{q : (q, x) \in s\}$, $T = \{q : (q, x) \in t\}$ are closed in the compact cube, hence compact, and disjoint. A smooth Urysohn function $g_x : \mathbb{R}^n \to [0, 1]$ is 0 near S and 1 near T. The points of the cube where $g_x \neq 0$ form a compact set disjoint from S, and the tube lemma gives an open $V_x \ni x$ such that $g_x(q) = 0$ whenever $(q, y) \in s$ and $y \in V_x$; likewise $g_x(q) = 1$ whenever $(q, y) \in t$ and $y \in V_x$, after shrinking V_x.

Step 3, gluing over X Chapter5/CubePartitions · exists_cubeProd_urysohn_w5. Let (ρ_x) be an sc-smooth partition of unity of X subordinate to (V_x), which exists by hypothesis, and

$$F(q, y) = \sum_x \rho_x(y)\, g_x(q).$$

The sum is locally finite, since ρ is, and each term is sc-smooth (an sc-smooth function of y times a smooth function of the cube coordinates); so F is sc-smooth. On s, every term with $\rho_x(y) \neq 0$ has $y \in V_x$, so $g_x(q) = 0$, and $F = 0$; on t, every such term has $g_x(q) = 1$, so $F = \sum_x \rho_x(y) = 1$; and F takes values in $[0, 1]$ as a convex combination of values in $[0, 1]$. *Conclusion.* $[0, 1]^n \times X$ admits sc-smooth partitions of unity when X does Chapter5/CubePartitions · admitsScPartitionsOfUnity_cubeProd, and so does the object M-polyfold of the cylinder bundle Chapter15/CylinderPartitions · SBLocalization.admitsScPartitionsOfUnity_cubeSEP. Gap G.181 is closed. What remains is a hypothesis on X: sc-smooth partitions of unity, which Corollary 15.3.10 does not state and Theorem 15.3.9 on the cylinder needs; witness $\mathbb{R}^n$ Chapter7/LocalDiffeo · rnPolyfold_admitsScPartitionsOfUnity. For $X = \mathbb{R}^n$ the cylinder's partitions of unity have also a direct proof, from Theorem 5.5.10 with the product charts of the cube and $\mathbb{R}^n$, whose finite-dimensional models have smooth partitions of unity (Proposition 5.5.11) Chapter15/Cylinder · SBLocalization.admitsScPartitionsOfUnity_cube_rn.

The glued data are structurable over the boundary (narrower: given one analytic statement). The text treats the data over $\{0, 1\} \times X$ as structurable because the Λ^i are. The formalization makes this precise by lifting the structures of Λ^i along the projection $[0, 1] \times X \to X$.

Lifted sections. For a section s of W (corrected to the zero of the fibre where $s(y)$ does not lie over y, a formality), the lift is $\tilde{s}(q, y) = ((q, y), s(y))$ Chapter15/CubeLift · SBLocalization.cubeLiftSec, a section of $\widetilde{W}$ Chapter15/CubeLift · SBLocalization.P_cubeLiftSec, and $\tilde{s}(p) = w$ iff $s(p_2) = w_2$ for w over p Chapter15/CubeLift · SBLocalization.cubeLiftSec_eq_iff. Along a morphism, $\tilde{\mu}$ acts on the W-component by μ (§XV.30), so the equivariance of lifted sections reduces to that of the sections: if $s'(t(\varphi_2)) = \mu(\varphi_2, s(s(\varphi_2)))$ then $\tilde{s}'(t(\varphi)) = \tilde{\mu}(\varphi, \tilde{s}(s(\varphi)))$ Chapter15/GlueStructurable · SBLocalization.cubeLiftSec_compat. The isotropy

group of $z = (q, x)$ maps to that of x by $(q, g) \mapsto g$ Chapter15/CubeLift · SBLocalization.cubeIso; it is an isomorphism, since the cube contributes only identities.

The key step: natural representations on a connected neighbourhood Chapter15/CubeLift · SBLocalization.cube_Γ_snd. Let V be a natural neighbourhood of z in the cylinder (Theorem 7.1.13), with V connected and lying over the domain of a natural neighbourhood N of z_2 in X. Then for $g \in G_z$ and $y \in V$, the X-part of the morphism $\Gamma_V(g, y)$ is $\Gamma_N(g_2, y_2)$. *Proof.* The maps $a(p) = \Gamma_V(g, p)_2$ and $b(p) = \Gamma_N(g_2, p_2)$ are continuous on V with values in the morphism space of X and have the same source p_2. Two such maps agree on an open set, by the étale property Chapter13/StrongBundlePullMap · isOpen_setOf_eq_of_src, and disagree on an open set, the morphism space being Hausdorff. These two open sets cover V; they agree at z, where both are g (the natural representation at its centre is the given isotropy element); and V is connected, so they agree on all of V. In particular the action of g on V is $\Phi_V(g)(y) = (y_1, \Phi_N(g_2)(y_2))$ Chapter15/CubeLift · SBLocalization.cube_Φ_eq, and the same holds for the bi-action of isotropy groups on morphisms between two such neighbourhoods Chapter15/GlueStructurable · SBLocalization.cube_biact_snd. The text uses this compatibility of the natural representations of $[0, 1] \times X$ and of X without comment; formally it is the uniqueness of continuous lifts through the source map.

Lifting one structure Chapter15/CubeLift · SBLocalization.liftStructure. A symmetric sc⁺-section structure of Λ on N (Definition 13.2.5, Part XIII) — an index set I with an action of G_{z_2}, sc⁺-sections s_i on N and weights σ_i, equivariant, representing Λ — gives a boundary symmetric structure (Definition 14.1.3, Part XIV) of any $\widetilde{\Lambda}$ with $\widetilde{\Lambda}(w) = \Lambda(w_2)$ over $V \cap \partial$: the same index set and weights, G_z acting through $G_z \cong G_{z_2}$, and the lifted sections $\tilde{s}_i$. Equivariance follows from that of the s_i with the key step: $\tilde{s}_{g\cdot i}(\Phi_V(g)(y))$ has W-component $s_{g_2\cdot i}(\Phi_N(g_2)(y_2)) = \mu(\Gamma_N(g_2, y_2), s_i(y_2))$, the W-component of $\tilde{\mu}(\Gamma_V(g, y), \tilde{s}_i(y))$. The representation: $\widetilde{\Lambda}(w) = \Lambda(w_2) = \sum_{i:s_i(y_2)=w_2} \sigma_i = \sum_{i:\tilde{s}_i(y)=w} \sigma_i$. Condition (1) of Definition 14.1.3, that the sections be sc⁺ on the local faces, is taken as given (below). The index set is that of a structure of an sc⁺-multisection, so it is not empty Chapter13/TightMultisection · SBLocalization.Decoration.nonempty_I.

The two sides. A point p of the cylinder is on the side "$t > \frac{1}{2}$" or "$t < \frac{1}{2}$" Chapter15/GlueStructurable · SBLocalization.cubeSide; both sides are open Chapter15/GlueStructurable · SBLocalization.isOpen_sideSet, every boundary point lies on its side Chapter15/GlueStructurable · SBLocalization.mem_sideSet_cubeSide, morphisms keep the time and hence the side Chapter15/GlueStructurable · SBLocalization.cubeSide_src, and on the boundary Λ_∂ is Λ^{side} Chapter15/GlueStructurable · SBLocalization.cubeGlue_eq_side. A function that is $\Lambda^{\text{side}}(w_2)$ over the boundary is a functor there when the Λ^i are Chapter15/GlueStructurable · SBLocalization.isBoundaryWFunctor_of_sides, since morphisms keep the side and act by μ on the W-component.

The glued structure. Let $(\mathcal{U}^b, S^b)$ be decorations of Λ^b with correspondences τ^b (Definition 13.3.6, Λ^b structurable). At a boundary point z let $O(z) = \{\text{side of } z\} \times \{p : p_2 \in U^{\text{side}}(z_2)\}$ Chapter15/GlueStructurable · SBLocalization.glue0, an open set containing z Chapter15/GlueStructurable · SBLocalization.isOpen_glue0 Chapter15/GlueStructurable · SBLocalization.mem_glue0. Theorem 14.1.6 (Part XIV) gives a good system for the boundary of the tame cylinder with paracompact orbit space whose neighbourhoods lie in the $O(z)$ Chapter14/BoundaryMultisection · EpGroupoid.theorem_14_1_6_hyp; its neighbourhoods are connected. Two facts make everything reduce to X. (i) A morphism of the good system from z to z' stays on one side, and its X-part is a morphism of $\mathcal{U}^b(z_2, z_2')$ Chapter15/GlueStructurable · SBLocalization.mor_glue, because its source and target lie in $O(z)$ and $O(z')$. (ii) The structure at z is the lift of the structure of $\Lambda^{\text{side}(z)}$ at z_2 Chapter15/GlueStructurable · SBLocalization.glueS. The correspondences are $\tilde{\tau}_{z,z'}(\varphi) = \tau^b_{z_2,z_2'}(\varphi_2)$ Chapter15/GlueStructurable · SBLocalization.glueTau (between different sides the full correspondence is put in, but there are no morphisms between them, so it is never used). The conditions of Definition 14.1.7 on correspon-

dences follow from those of τ^b: local constancy and finiteness of the image along the X-parts; symmetry under inversion; the diagonal condition at isotropy elements, by the key step $\Gamma_V(g,y)_2 = \Gamma_N(g_2,y_2)$; equivariance under the bi-action of isotropy groups, by its form for morphisms; and the compatibility with the sections, by the equivariance of lifted sections above.

Structurability `Chapter15/GlueStructurable · SBLocalization.isBoundaryStructurable_of_sides`. For tame X with $d_X \equiv 0$ and paracompact $|X|$, structurable Λ^0, Λ^1, and the analytic statement below, any $\widetilde{\Lambda}$ equal to $\Lambda^{\mathrm{side}}(w_2)$ over the boundary is structurable over the boundary: functor by the side lemma, a structure at every boundary point by the lift, the decoration and correspondences as just built. In particular the glued data are `Chapter15/GlueStructurable · SBLocalization.isBoundaryStructurable_cubeGlue_w5`. Their index sets are those of the Λ^i, hence not empty, in agreement with the charging above.

The analytic statement `Chapter15/GlueStructurable · SBLocalization.CubeLiftFace`: for an sc$^+$-section s on an open $U \subset X$, the lift $\tilde{s}$ is sc$^+$ on the local faces through the points of $([0,1]\times U)\cap\partial([0,1]\times X)$, condition (1) of Definition 14.1.3. It is a statement in the text's setting, which the text uses without comment (that the lift of an sc$^+$-section along the projection is sc$^+$), but it is not proved: Part I's lemma on sc$^+$-sections in charts is available only for charts with domain inside the open set, and the pull-back lemma of Part I is stated for sc-smooth, not sc$^+$, sections. It is taken as a hypothesis and has no witness; a witness would be the general proof. This is gap G.193.

XV.33 Corollary 15.3.10 (3): the statement with the charged Theorem 15.3.9, the last paragraph of the proof, and Remark 15.3.11

Corollary 15.3.10 (3) (narrower) `Chapter15/ChargedExtensionCylinder · SBLocalization.corollary_15_3_10_3_charged`. *Statement.* Let $d_X \equiv 0$, $|X|$ paracompact, f an sc-Fredholm section functor with Part I's tame germ data and $|S_f|$ compact, and (N^i, U^i, Λ^i), $i = 0, 1$, structurable regular perturbations of f. Assume on the cylinder: the charged statement of Theorem 15.3.9 `Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_statement` (§XV.27), a tame strong bundle chart at every object, sc-smooth partitions of unity, and, of the glued data Λ_∂ of §XV.32, structurability over the boundary and the face condition. Then there is $\widetilde{\Lambda}$ such that $(\widetilde{N},\widetilde{U},\widetilde{\Lambda})$ is a structurable regular perturbation of $\tilde{f}$, with $(\widetilde{N},\widetilde{U})$ of (2), $\widetilde{\Lambda} = \Lambda^i$ over $\{i\}\times X$, and $\widetilde{\Theta} = \widetilde{\Lambda}\circ\tilde{f}$ a branched ep$^+$-subgroupoid with compact $|\operatorname{supp}\widetilde{\Theta}|$: the text's "compact cobordism $\widetilde{\Theta}$ between Θ_0 and Θ_1". The text's (3) does not repeat the pairs; it is stated for different (N^i, U^i), as in (2).

Proof, as the text's, with every input named. (i) X is tame (§XV.30), hence so is the cylinder, and $\partial([0,1]\times X)$ lies over $t \in \{0,1\}$. (ii) $(\widetilde{N},\widetilde{U})$ controls the compactness of $\tilde{f}$, by (2) (§XV.31). (iii) The data on the cylinder: $\tilde{f}$ is an sc-Fredholm section functor with tame germ data and compact solution set, and $|[0,1]\times X|$ is paracompact (§XV.30). (iv) The boundary data: Λ_∂ is structurable over the boundary (hypothesis), charges every boundary fibre, has boundary domain support in $\widetilde{U}$, and satisfies $\widetilde{N}(\Lambda_\partial) \le 1$ and < 1 on the boundary (§XV.32, the last from $N^i(\Lambda^i) < 1$). (v) Apply the charged Theorem 15.3.9 on the cylinder with $h \equiv 1$. It returns $\widetilde{\Lambda}$ structurable, equal to Λ_∂ over the boundary, with domain support in $\widetilde{U}$, $\widetilde{N}(\widetilde{\Lambda}) < 1$, $(\tilde{f},\widetilde{\Lambda})$ transversal, and $\widetilde{\Lambda}\circ\tilde{f}$ branched with compact support. (vi) These are the clauses of a regular perturbation; and over $t = i$ the points lie in the boundary (§XV.30), where $\widetilde{\Lambda} = \Lambda_\partial = \Lambda^i(w_2)$ by §XV.32. The declaration concludes "branched and compact"; the text's "tame" for $\widetilde{\Theta}$ would come from general position, which the statement of Theorem 15.3.9 does not conclude.

The hypotheses, discharged and open. Of the hypotheses that the declaration takes, two are proved for

the corollary's data in §XV.32: the partitions of unity of the cylinder from those of X, and the structurability of Λ_∂ from the structurability of the Λ^i, given the analytic statement on lifted sections; the declarations compose, and the composite is not stated as one declaration. The remaining inputs are: (a) the charged Theorem 15.3.9 on the cylinder, which holds given the relative local families on the cylinder `Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_of_local_rel` (§XV.29; gap G.178); (b) tame strong bundle charts at every object of the cylinder, the product of a tame strong bundle chart of W with the tame charts of $[0,1]$, which is not formalized (gap G.189); (c) the analytic statement on lifted sections (gap G.193); (d) the face condition of Λ_∂ (gap G.180); (e) sc-smooth partitions of unity on X, which the corollary does not state. *Reading of (d).* The text's proof says only $\widetilde{U} = [0,1] \times U$ and $\widetilde{f}(t,x) = f(x)$ and does not say how the face condition of the glued data is checked; presumably from the transversality of (f, Λ^i), since $T^R_{(i,x)}([0,1] \times X) = \{0\} \times T_x X$ when $d_X \equiv 0$, so that the reduced surjectivity on the face is the surjectivity of $T(f, \Lambda^i)(x)$.

Remark: the forms with the uncharged statement. The same conclusion is also proved from the uncharged Lean statement of Theorem 15.3.9 on the cylinder: with six hypotheses on arbitrary boundary data Λ_b `Chapter15/RegularPerturbations · SBLocalization.corollary_15_3_10_3_hyp`; the same with tameness and paracompactness of the cylinder derived `Chapter15/Cylinder · SBLocalization.corollary_15_3_10_3_ty`; for the glued data of two regular perturbations `Chapter15/CylinderGlue · SBLocalization.corollary_15_3_10_3_glue_hyp`; with the partitions of unity of X `Chapter15/CylinderPartitions · SBLocalization.corollary_15_3_10_3_pu_w5` `Chapter15/CylinderPartitions · SBLocalization.corollary_15_3_10_3_glue_w5`; and with the analytic statement on lifted sections in place of structurability `Chapter15/GlueStructurable · SBLocalization.corollary_15_3_10_3_struct_w5`. That statement, which admits boundary data with empty index sets, does not hold for the cylinder of a nonempty X under the corollary's hypotheses `Chapter15/ChargedExtensionCylinder · SBLocalization.not_theorem_15_3_9_statement_cube_w2`: the point $(0,x)$ is a boundary point, $\widetilde{f}$ and the pair $(\widetilde{N}, \widetilde{U})$ of (2) for the pair (N,U) taken twice satisfy its hypotheses, and the general counterexample of §XV.27 applies. So these forms are vacuous for nonempty X; this is a property of our formalization, not of the text, whose boundary data are sc$^+$-multisections with nonempty index sets. They are the steps at which the lemmas of §§XV.30–XV.32 were proved, and those lemmas discharge the corresponding hypotheses of the charged form above.

Witnesses, and their limits. On $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$ with $\Lambda^0 = \Lambda^1 = 0$, every hypothesis of the forms above on the boundary data holds together with tameness, $d_X \equiv 0$ and the paracompactness of the cylinder `Chapter15/Cylinder · SBLocalization.corollary_15_3_10_3_boundary_witness`, and the glued data are structurable over the boundary and satisfy the face condition `Chapter15/CylinderGlue · SBLocalization.corollary_15_3_10_3_glue_witness`. There the fibres are 0, so the projection $W \to X$ is injective, every operator onto a fibre is onto `Chapter15/Cylinder · SBLocalization.isReducedOntoAtPt_of_injective` and the face condition is automatic `Chapter15/Cylinder · SBLocalization.isBoundaryFaceOnto_of_injective`; the zero multisection is 1 at the only point of each fibre `Chapter15/Cylinder · SBLocalization.zeroMultisection_eq_one_of_injective`, the glued data are the zero multisection of the cylinder, and that is structurable over the boundary `Chapter14/BoundaryStructured · SBLocalization.isBoundaryStructurable_zero`. These witnesses are **weak**: zero fibres, and they show only that the hypotheses are consistent. That $\Lambda^i = 0$ are themselves regular perturbations on that example is not rechecked. The analytic statement on lifted sections and the tame strong bundle charts of the cylinder have no witness.

The last paragraph of the proof (same). The text closes with: if (N,U) and (N',U') control compactness, so does $(N'',U'') = (\max\{N,N'\}, U \cap U')$, and a perturbation for it is controlled by both pairs, so one can connect Λ with Λ'' and Λ'' with Λ'. *Proof.* (i) $\max\{N,N'\}$ is an auxiliary norm of

(W,μ) Chapter15/CylinderGlue · SBLocalization.isAuxNorm_max_ty: Part I's lemma for the maximum of two auxiliary norms, and invariance from that of N and N'. (ii) (N'',U'') controls compactness Chapter15/CylinderGlue · SBLocalization.controlsCompactness_max: $U\cap U'$ is open, saturated (a morphism with source in both saturated sets has its target in both) and contains S_f; and its sublevel set $\{x\in U\cap U' : \max\{N,N'\}(f(x))\le 1\}$ lies in the sublevel set of (N,U), since $N\le\max\{N,N'\}$, whose orbit set has compact closure. (iii) For an sc⁺-multisection, $N(\Lambda)\le\max\{N,N'\}(\Lambda)$ pointwise Chapter15/CylinderGlue · SBLocalization.pointwiseNorm_le_max_left: the supremum defining $N(\Lambda)(x)$ is attained at some w, and $N(w)\le\max\{N,N'\}(w)\le\max\{N,N'\}(\Lambda)(x)$. (iv) Hence a regular perturbation for (N'',U'') is one for (N,U) Chapter15/CylinderGlue · SBLocalization.IsRegularPerturbation.of_max_left and for (N',U') Chapter15/CylinderGlue · SBLocalization.IsRegularPerturbation.of_max_right: domain support in $U\cap U'\subset U$, norm $N(\Lambda)\le N''(\Lambda)<1$, structurability and transversality unchanged, and the control of compactness by (N,U) given. *A remark on its role.* The formal (3) takes the two regular perturbations with different pairs (N^0,U^0), (N^1,U^1) from the start, through the interpolated pair of (2), so it does not need this paragraph; the paragraph is proved as printed, and the two-step connection it describes, (3) applied twice, is not stated as a separate declaration.

Remark 15.3.11 (nothing to formalize) is prose: without orientations the perturbation theory gives only rational chains, and with f oriented, $\Lambda\circ\tilde f$ carries a natural orientation and gives invariants, which is §15.4 (§§XV.34–XV.37).

XV.34 Oriented formal sums, Theorem 15.4.1 and Definition 15.4.2 (2017: Theorem 15.6, Definition 15.7)

§15.4 opens (p. 700) with a list of standing data, Assumption 15.4: a strong bundle over a tame ep-groupoid, an oriented sc-Fredholm section functor (f,o) with compact $|S_f|$, and an sc⁺-multisection Λ with $T(f,\Lambda)$ onto on $\mathrm{supp}(\Lambda\circ f)$, kernels in good position at the boundary, and $\Theta=\Lambda\circ f$ a branched ep⁺-subgroupoid. Theorem 15.4.1 then lifts the tangent functor $T\Theta$ to oriented tangent spaces, using o. The text's route has two layers. The first is linear algebra at one point y: every summand $(f-s_i)'(y)$ of $T(f,\Lambda)(y)$ inherits an orientation $o_{i,y}$ from o, and the oriented formal sum $\hat T_{((f,o),\Lambda)}(y)=\sum_{f(y)=s_i(y)}\sigma_i\cdot((f-s_i)'(y),o_{i,y})$ does not depend on the local section structure. The second layer is geometry: for y in the support the operators are onto, $o_{i,y}$ orients $\ker(f-s_i)'(y)$, these orientations vary continuously along the branch $M_i=\{f=s_i\}$, and $\hat T_{(\Theta,o)}(y)=\sum\sigma_i\cdot T_y(M_i,o_i)$ is an orientation of Θ in Chapter 9's sense. The formalization proves the first layer completely, at a chart point, and the identification of the kernel orientation; the second layer is gap G.159 (§XV.38).

The setting: chart points and $\mathrm{Lin}(f,y)$**.** Part I's orientation theory of sc-Fredholm sections (Chapter 6) is formalized at a *chart point*: a strong bundle chart c around x together with a level-1 point z of the model over $\varphi(x)$ Chapter6/LinSet · ChartPoint. There T_xX is read as $T_zO=\mathrm{im}\,Dr(z)$ and the fibre W_x as $K_z=\mathrm{im}\,\rho(z)$. Part I's $\mathrm{Lin}(f,x)$ (Definition 6.2.1) is the set of operators $T_zO\to K_z$ of the form $(f+s)'(x)+a$, with s an sc⁺-section through $-f(x)$ and a an sc⁺-operator Chapter6/LinSet · ChartPoint.linSet; for one fixed s it is $(f+s)'(x)+\{\text{sc⁺-operators}\}$ Chapter6/LinSet · ChartPoint.mem_linSet_iff, it is convex Chapter6/LinSet · ChartPoint.convex_linSet, and at a smooth point it is not empty when sc⁺-sections pass through every smooth point of the fibre Chapter6/LinSet · ChartPoint.linSet_nonempty, the standing hypothesis of §12.5. Its members are Fredholm Chapter6/LinOrientation · ChartPoint.isFredholm_of_mem_linSet, so the determinant lines form a line bundle $\mathrm{DET}(f,x)$ over $\mathrm{Lin}(f,x)$ Chapter6/LinOrientation · ChartPoint.detLin, and Or_x^f is the set of its orientations (Definition 6.6.2) Chapter6/LinOrientation · ChartPoint.Or. Since $\mathrm{Lin}(f,x)$

is convex, hence contractible, an orientation is determined by its value at any one member: $o \mapsto o(L)$ is a bijection of Or_x^f with the two rays of $\det L$ Chapter6/LinOrientation · ChartPoint.orEquivRay, because two orientations of a line bundle over a preconnected base that agree on one fibre agree everywhere Chapter6/LineBundleOrientation · LineOrientation.eq_of_apply_eq.

Oriented formal sums (restated). At a chart point p, an *oriented member of* $\mathrm{Lin}(f,x)$ is a pair (L,r) with $L \in \mathrm{Lin}(f,x)$ and r a ray of $\det L$ Chapter15/OrientedLinearizations · ChartPoint.OrLin. The text's $\widehat{\mathrm{Gr}}_F(x)$ (p. 701) is the set of finite formal sums of oriented operators with weights in $\mathbb{Q}^+$, read here as finitely supported functions on oriented members Chapter15/OrientedLinearizations · ChartPoint.GrFHat, as $\mathrm{GrF}(x)$ was read in §XV.1. The forgetful map f_F sends $\sum \sigma \cdot (L,r)$ to $\sum \sigma \cdot L$ Chapter15/OrientedLinearizations · ChartPoint.forgetOr. *The reading*: the text's oriented operators are all sc-Fredholm operators $T_xX \to W_x$; here they are the members of $\mathrm{Lin}(f,x)$, which are exactly the operators that o can orient, and all operators that occur in $T(f,\Lambda)(x)$ are of this kind (below).

f_F is 2–1 Chapter15/OrientedLinearizations · ChartPoint.exists_two_orLin: over every $L \in \mathrm{Lin}(f,x)$ there are exactly two oriented members. *Proof.* $\det L$ is a real line, since L is Fredholm Chapter6/FredholmDet · finrank_fredholmDet, and a real line has exactly two rays, a nonzero vector v and $-v$ spanning them Chapter15/OrientedLinearizations · ChartPoint.exists_two_rays_of_finrank_eq_one. Two oriented members over the same L are equal iff their rays are.

The canonical lift of a formal sum. For $o \in \mathrm{Or}_x^f$ and $L \in \mathrm{Lin}(f,x)$, $(L, o(L))$ is the oriented member L inherits from o Chapter15/OrientedLinearizations · ChartPoint.orLin, and $L \mapsto (L,o(L))$ is injective Chapter15/OrientedLinearizations · ChartPoint.orLin_injective. The canonical lift of a formal sum $w = \sum \sigma_L \cdot L$ of members of $\mathrm{Lin}(f,x)$ is its push-forward along this map, $\sum \sigma_L \cdot (L, o(L))$ Chapter15/OrientedLinearizations · ChartPoint.canonLift. Four facts follow, each a short computation with push-forwards of finitely supported functions.

- *f_F undoes the lift*: $f_F(\mathrm{lift}_o(w)) = w$, read as a sum of operators Chapter15/OrientedLinearizations · ChartPoint.forgetOr_canonLift, since $f_F \circ (L \mapsto (L,o(L)))$ is the inclusion of $\mathrm{Lin}(f,x)$. The lift is additive and commutes with finite sums and single terms Chapter15/OrientedLinearizations · ChartPoint.canonLift_add Chapter15/OrientedLinearizations · ChartPoint.canonLift_sum Chapter15/OrientedLinearizations · ChartPoint.canonLift_single.
- *Every summand carries the orientation induced by o* Chapter15/OrientedLinearizations · ChartPoint.snd_eq_of_mem_support_canonLift: the support of a push-forward lies in the image of the support.
- *Uniqueness* Chapter15/OrientedLinearizations · ChartPoint.canonLift_unique: a formal sum W of oriented members whose image under f_F is w and all of whose summands carry the orientation induced by o equals $\mathrm{lift}_o(w)$. *Proof.* On the support of W the identity agrees with $q \mapsto (q_1, o(q_1))$, so W is the push-forward of itself along that map; this push-forward factors as the push-forward along the first projection, which is w, followed by the lift.
- *The lift sees o* Chapter15/OrientedLinearizations · ChartPoint.canonLift_injective_o: two orientations o, o' that give the same lift of a nonzero sum w are equal. *Proof.* Take L in the support of w. Then $(L,o(L))$ lies in the support of the lift, hence of the lift by o', so by the previous point it is $(L,o'(L))$, and $o(L) = o'(L)$. Since $\mathrm{Lin}(f,x)$ is convex, hence preconnected, two orientations of $\mathrm{DET}(f,x)$ that agree at L agree everywhere (Part I, as above).

Since operators of $\mathrm{Lin}(f,x)$ are determined by their values, formal sums of members with the same image as sums of operators are equal Chapter15/OrientedLinearizations · ChartPoint.mapDomain_val_injective, and so have the same lift Chapter15/OrientedLinearizations · ChartPoint.canonLift_eq_of_mapDomain_eq.

The kernel orientation of an onto member. The text identifies $\Lambda^{\max}\ker L$ with $\det L = \Lambda^{\max}\ker L \otimes (\Lambda^{\max}\operatorname{coker} L)^*$ when L is onto (p. 702). Formally, for $L \in \mathrm{Lin}(f,x)$ onto and $N \subset E_0$ the image of $\ker L$ under the inclusion $T_zO \subset E_0$, the ray $o(L)$ is carried to a ray of $\Lambda^{\max}N$ `Chapter15/OrientedLinearizations · ChartPoint.orKer` by Part I's map $\det L \cong \Lambda^{\max}\ker L \cong \Lambda^{\max}N$ `Chapter6/SolutionOrientation · surjRay`, built from the determinant of an onto operator (the cokernel being $\{0\}$) and the isomorphism $\ker L \cong N$ `Chapter6/SolutionOrientation · kerEquivOfMap`. Composed with $o \mapsto o(L)$ this is a bijection $\mathrm{Or}^f_x \cong \mathrm{Ray}(\Lambda^{\max}N)$ `Chapter15/OrientedLinearizations · ChartPoint.orKerEquiv Chapter15/OrientedLinearizations · ChartPoint.orKerEquiv_apply`: the orientation of f at x and the induced orientation of the kernel determine each other. The kernel is finite-dimensional `Chapter15/OrientedLinearizations · ChartPoint.finiteDimensional_of_mem_linSet`, and the ray can be read as an orientation of the subspace N in Mathlib's sense, through Part I's pull-back of rays to orientations `Chapter6/SolutionSetOrientation · pullOr Chapter15/OrientedLinearizations · ChartPoint.orKerOrientation`: a basis $b_1,\dots,b_k$ of N is positive iff $b_1 \wedge \cdots \wedge b_k$ lies in the ray `Chapter15/OrientedLinearizations · ChartPoint.orientation_eq_orKerOrientation_iff`. This orientation still determines o `Chapter15/OrientedLinearizations · ChartPoint.orKerOrientation_injective`. *Proof.* Fix a basis b of N; its orientation is either the orientation from o or its negative. In the first case the characterization above says that the ray from o is the ray of $b_1 \wedge \cdots \wedge b_k$, and the same holds for o', whose orientation is the same by hypothesis. In the second case the ray from o is not that of the wedge (the characterization would make the orientations equal, while an orientation is never its negative), so, $\Lambda^{\max}N$ being a line, it is the opposite ray `Chapter6/SolutionSetOrientation · ray_eq_or_eq_neg_of_finrank_eq_one`; again the same for o'. In both cases the two rays agree, and the bijection $\mathrm{Or}^f_x \cong \mathrm{Ray}(\Lambda^{\max}N)$ gives $o = o'$.

The operators $(f-s)'(y)$ as members of $\mathrm{Lin}(f,y)$. The bridge between §15.1 and Part I is the chart point at which the linearization of §§XV.7–XV.8 is read: for a chart c around $y \in X_1$, the point z is the level-1 lift of $\varphi(y)$ `Chapter15/CanonicalLift · SBLocalization.liftPt`. Let s be an sc$^+$-section on an open O containing the domain of c, with $f(y) = s(y)$. Then $\hat f(\varphi(y)) = \hat s(\varphi(y))$ `Chapter15/CanonicalLift · SBLocalization.principal_eq_of_eq`, and the derivative $D((\hat f - \hat s)\circ r)(z)$ of §XV.10 takes values in K_z `Chapter15/CanonicalLift · SBLocalization.subDeriv_mem_K`: the principal part of the section $f-s$ maps $r(U)$ into the fibres K of the retract, and at a zero the derivative of such a map lies in K_z (Part I's lemma on derivatives of sections of a strong bundle retract). Restricted to T_zO it is an operator $(f-s)'(y) : T_zO \to K_z$ `Chapter15/CanonicalLift · SBLocalization.subOp Chapter15/CanonicalLift · SBLocalization.coe_subOp`; composed with $K_z \subset F$ `Chapter15/CanonicalLift · SBLocalization.toF`, an injective operation `Chapter15/CanonicalLift · SBLocalization.toF_injective`, it is the operator of the chart sum of Theorem 15.1.1 `Chapter15/CanonicalLift · SBLocalization.toF_subOp`.

Lemma (extra) `Chapter15/CanonicalLift · SBLocalization.subOp_mem_linSet`: at a smooth y, under §12.5's standing hypothesis, $(f-s)'(y) \in \mathrm{Lin}(f,y)$. This is what lets o_y orient every summand of $T(f,\Lambda)(y)$; the text takes it from §12.5 (p. 701, "see Section 12.5"). *Proof.* By the standing hypothesis there is an sc$^+$-section s_0 with $(f+s_0)(y) = 0$ `Chapter6/LinSet · ChartPoint.linSet_nonempty`, and by Part I's description for one section it suffices to write $(f-s)'(y) = (f+s_0)'(y) + a$ with a an sc$^+$-operator. In the chart, both s and s_0 are sc$^+$, so their principal parts lift to the shifted fibre F^1, and these lifts composed with r are sc-smooth into the shift `Chapter3/IndexLocallyConstantLocal · StrongBundle.HasScPlusSectionsThrough` (for s through Part I's chart lemma for local sc$^+$-sections, §XV.10). Put $h = (\hat s_1 + \hat s_{0,1})\circ r$. On U,

$$(f \hat{+} s_0)\circ r = (\hat f - \hat s)\circ r + \iota \circ h,$$

$\iota : F^1 \to F^0$ the inclusion, an identity checked pointwise from the principal part of a sum of sections

and the lifts. Differentiating at z gives $D((f \mathbin{\hat{+}} s_0)\circ r)(z) = D((\hat f - \hat s)\circ r)(z) + \iota \circ Dh(z)$. Here $Dh(z)$ is an sc-operator into the shifted space, because h is sc-smooth and z is smooth; its values composed with ι lie in K_z, being the difference of two derivatives with values in K_z. So $b = \iota \circ Dh(z)$ restricted to $T_zO \to K_z$ is an sc⁺-operator, by Part I's criterion for operators that factor through the shift `Chapter6/LinSet · ChartPoint.isScPlusOp_of_shift`, and $(f-s)'(y) = (f+s_0)'(y) + (-1)b$. The standing hypothesis holds whenever X has sc-smooth bump functions; it is the hypothesis Part XII carries for §12.5.

The formal sum with members of $\mathrm{Lin}(f,y)$**.** Let (s_i,σ_i) be a local section structure of Λ on an open O (Definition 13.2.1) and c a chart with domain in O. At a smooth y in the domain, $\sum_{i:s_i(y)=f(y)} \sigma_i \cdot (f-s_i)'(y)$ is a formal sum of members of $\mathrm{Lin}(f,y)$ `Chapter15/CanonicalLift · SBLocalization.linW`. Its image as a sum of operators $T_zO \to F$ is the chart sum $\sum_{\hat s_i = \hat f} \sigma_i(\hat f - \hat s_i)'(z)$ of Theorem 15.1.1 in a chart (§XV.7) `Chapter15/CanonicalLift · SBLocalization.mapDomain_toF_linW`. *Proof.* Term by term. The condition $s_i(y) = f(y)$ is equivalent to $\hat s_i(\varphi(y)) = \hat f(\varphi(y))$ `Chapter15/CanonicalLift · SBLocalization.eq_iff_principal_eq`, because the chart is injective on the fibre over y and maps $s_i(y)$, $f(y)$ to $(\varphi(y), \hat s_i(\varphi(y)))$, $(\varphi(y), \hat f(\varphi(y)))$; where it holds, the operator of the term is that of the chart sum (above), and where it fails both terms are 0.

Theorem 15.4.1 (narrower) `Chapter15/CanonicalLift · SBLocalization.theorem_15_4_1_lift`. Let f be an sc-Fredholm section, (s_i,σ_i) a local sc⁺-section structure of Λ on an open O, c a chart with domain in O, y a smooth point of the domain, and $o \in \mathrm{Or}^f_y$ read at the chart point of y. Then $\hat T = \mathrm{lift}_o(\sum_{s_i(y)=f(y)} \sigma_i \cdot (f-s_i)'(y))$ satisfies (1) $f_F(\hat T) = T(f,\Lambda)(y)$, the chart sum of Theorem 15.1.1; (2) every summand of $\hat T$ carries the orientation induced by o; and $\hat T$ is the only element of $\widehat{\mathrm{Gr}}_F(y)$ with (1) and (2). *Proof.* The general characterization `Chapter15/CanonicalLift · SBLocalization.canonLift_spec`: for any formal sum w of members of $\mathrm{Lin}(f,y)$ whose image as operators is a given T, the lift of w maps to T (by $f_F \circ \mathrm{lift}_o = \mathrm{id}$), its summands carry o, and any W with these two properties has $f_F(W) = w$, because the passage from formal sums of members to formal sums of operators $T_zO \to F$ is injective (inclusion of $\mathrm{Lin}(f,y)$, then the injective $L \mapsto \iota \circ L$), so the uniqueness of the lift applies. With w the formal sum above and T the chart sum, the hypothesis of the characterization is the previous paragraph. *The formula* is the text's, $\hat T = \sum_{f(y)=s_i(y)} \sigma_i \cdot ((f-s_i)'(y), o((f-s_i)'(y)))$ `Chapter15/CanonicalLift · SBLocalization.canonLift_linW_eq_sum`, by additivity of the lift on the finite sum over i.

Independence of the local structure `Chapter15/CanonicalLift · SBLocalization.theorem_15_4_1_indep`: two local section structures (s_i,σ_i) on O and (t_j,τ_j) on O', both containing the domain of c, give the same $\hat T$. This is the text's argument (p. 701), that the occurring operators do not depend on the choice. *Proof.* By Theorem 15.1.1 in a chart (§XV.7) the two chart sums agree at the point `Chapter15/Linearization · SBLocalization.linSumChart_eq`. Both are the images of the corresponding formal sums of members of $\mathrm{Lin}(f,y)$, and that passage is injective, so the two formal sums of members agree, and so do their lifts.

Definition 15.4.2 (narrower) `Chapter15/CanonicalLift · SBLocalization.canonicalLift`: the canonical lift $\hat T_{((f,o),\Lambda)}(y) \in \widehat{\mathrm{Gr}}_F(y)$, read at the chart point. *The kernel orientations.* For an onto summand, surjectivity onto K_z is the chart surjectivity of §XV.10 `Chapter15/CanonicalLift · SBLocalization.surjective_subOp_iff` (onto K_z means: every k in the range of $\rho(z)$ is hit, and K_z is that range), and $o_{i,y}$ is the orientation of $\ker(f-s_i)'(y)$ induced by o_y `Chapter15/CanonicalLift · SBLocalization.branchOr`, the kernel-orientation construction above applied to the member $(f-s_i)'(y)$. It determines o_y `Chapter15/CanonicalLift · SBLocalization.branchOr_injective`, by the bijection $\mathrm{Or}^f_y \cong \mathrm{Ray}(\Lambda^{\max} N)$.

Narrower. Theorem 15.4.1 lifts $T\Theta$, a section functor of oriented tangent planes of Θ, to $\widehat{\mathrm{Gr}}(X)$ of Chapter 9. What is proved is the pointwise layer, in $\widehat{\mathrm{Gr}}_F(y)$ at a chart point: the lift of $T(f,\Lambda)(y)$, its formula, its uniqueness, its independence of the local structure, and the kernel orientations $o_{i,y}$. Not formalized

(gap G.159, §XV.38): that the tangent space of M_i at y is the kernel of $(f - s_i)'(y)$, the continuity of $y \mapsto o_{i,y}$ along M_i as an orientation of a submanifold in Chapter 9's sense, the naturality under morphisms ($\varphi_*(L, o) = (\varphi_* L, \varphi_* o)$ in the text's category $\widehat{\mathrm{Gr}}_F(X)$), and the assembly into an orientation of Θ. So Theorem 15.4.3 and Corollary 15.4.4 below take the orientation of Θ as data. *Hypotheses.* §12.5's standing hypothesis (sc⁺-sections through smooth points), which bump functions give; and y smooth, where $\mathrm{Lin}(f, y)$ is defined. Neither is new: the text works at smooth points and refers to §12.5 for the orientations. The chart-point reading of $\widehat{\mathrm{Gr}}_F$ is the reading of GrF in §XV.1, with the operators of $\mathrm{Lin}(f, y)$.

XV.35 Theorem 15.4.3 (2017: 15.7): branched, compact, Stokes

The theorem (pp. 702–703) has two parts: under (1) $N(\Lambda) \leq 1$, (2) $T(f, \Lambda)$ onto on the support and (3) good position at the support points in ∂X, $\Theta = \Lambda \circ f$ is a compact, tame, branched ep⁺-subgroupoid, oriented by o; and Stokes' theorem holds for it, with the effective version under the local unique continuation property. The first part is a statement of §§15.2–15.3, proved here from them. The second is Part IX's Stokes theorem applied to Θ, once Θ carries an orientation by oriented tame structures.

The local branching at a point of good position `Chapter15/PerturbedStokesInvariants · SBLocalization.localBranching_of_isGoodPositionAt`. If (f, Λ) is in good position at y (Definition 15.2.4, §XV.15) and f has tame germ data, then $z \mapsto \Lambda(f(z))$ has a local branching structure at y in the sense of Definition 9.1.2 (2)–(4) (Part IX). *Proof.* Theorem 15.2.5 at y (§XV.16) `Chapter15/BoundaryPerturbation · SBLocalization.theorem_15_2_5_hyp` gives a natural representation $U(y)$, a local section structure $(s_i, \sigma_i)_{i \leq k}$ and the sets $M_i = \{z \in U(y) : f(z) = s_i(z)\}$, each a smooth submanifold properly embedded in $U(y)$, the count $\Lambda(f(z)) = \sum_{f(z) = s_i(z)} \sigma_i$ on $U(y)$, and the clause that only the branches through $f(y)$ meet f in $U(y)$. The branching structure is indexed by the branches through $f(y)$, $\{i : s_i(y) = f(y)\}$, with the sheets M_i and the weights σ_i; each sheet contains y, is a submanifold and properly embedded. The count is a chain of four rewritings: the count formula as a sum over all i of σ_i or 0; restriction of the sum to the branches through $f(y)$, the others contributing 0 at points of $U(y)$ by the last clause; and two changes of the index type (a subtype, then its lift to the universe of X) which do not change the sum.

Branched and compact `Chapter15/PerturbedStokesInvariants · SBLocalization.theorem_15_4_3_isBranched_hyp` (narrower). Let f be an sc-Fredholm section functor with tame germ data, (N, U) control the compactness of f (Definition 15.3.1, §XV.17), and let Λ be an sc⁺-multisection with domain support in U, $N(\Lambda) \leq 1$, transversal (Definition 15.2.1, §XV.12), and in good position at every support point in ∂X. Then $\Theta = \Lambda \circ f$, read with values in $\mathbb{Q}$, is a branched ep⁺-subgroupoid with compact support. *Proof.* The compactness of $|\operatorname{supp} \Theta|$ is that of the "in particular" of Theorem 15.3.7 (§XV.21) `Chapter15/GeneralPositionBranched · SBLocalization.isCompact_orbitSupp_comp`: the support lies in the sublevel set $\{x \in U : N(f(x)) \leq 1\}$, whose orbit set has compact closure, and is closed. Compactness gives the paracompactness of the orbit space of the support, Definition 9.1.2 (1). Θ is nonnegative, a functor (because f and Λ are) `Chapter15/GeneralPositionBranched · SBLocalization.isFunctorial_comp`, and its support consists of smooth points under the tame germ data `Chapter15/Transversality · SBLocalization.mem_smoothSet_of_pos`. The local branching at a support point z is a case split. If $z \in \partial X$, (3) and the previous paragraph. If not, $d_X(z) = 0$, and Remark 15.2.3 at an interior point of transversality (§XV.14) `Chapter15/Transversality · SBLocalization.remark_15_2_3_hyp` gives the structure. *Readings.* The text's (2) is transversality in the sense of Definition 15.2.1 (the operators of $T(f, \Lambda)$ are onto on the support); its (3), "in good position to ∂X", is Definition 15.2.4; "tame" for Θ is the tame form of §XV.21. The tameness of X, which the text assumes, is not used: good position carries what is needed near the boundary points.

Narrower only through the tame germ data of f, inherited from §15.2 (§XV.13).

Theorem 15.4.3 (narrower) `Chapter15/PerturbedStokesInvariants · SBLocalization.theorem_15_4_3_hyp`. Under the hypotheses above, together with sc-smooth partitions of unity on X (Definition 7.5.5) and an orientation $\hat{T}$ of Θ (Definition 9.3.x of Part IX: a lift of $T\Theta$ to oriented tangent planes) represented at every support point by an oriented tame structure of dimension $m+1$, $m \geq 1$: Θ is a compact branched ep⁺-subgroupoid, and for every $\omega \in \Omega^m_{\mathrm{ep},\infty}(X)$

$$\int_{(\Theta,\hat{T})} d\omega = \mu^{\partial\Theta}_{\omega}(\partial S),$$

the boundary measure of Theorem 9.5.15 of the whole boundary $\partial S = |\operatorname{supp} \partial\Theta|$, which is the text's $\int_{\partial(\Theta,o)} \omega$. *Proof.* The first part is the lemma above; the identity is Part IX's Theorem 9.5.17 `Chapter9/StokesTextHypotheses · EP.theorem_9_5_17`, whose hypotheses are exactly these: partitions of unity on X, Θ compact and branched, oriented, and tame of dimension $m+1$. The boundary measure `Chapter9/StokesTextHypotheses · EP.boundaryMeasure` is defined on the σ-algebra $L(\partial S)$ of Definition 9.5.14 over the orbit space of the support of $\partial\Theta$ (Definition 9.2.16) `Chapter9/Boundary · EpGroupoid.boundaryTheta`.

The effective version `Chapter15/PerturbedStokesInvariants · SBLocalization.theorem_15_4_3_eff_hyp`: if moreover X has the local unique continuation property (Definition 7.2.18) `Chapter7/ReducedCriterion · EpGroupoid.IsLUC`, then $\oint_{(\Theta,\hat{T})} d\omega$ is the effective boundary measure of ∂S (Theorem 9.5.16), by Part IX's Theorem 9.5.18 `Chapter9/StokesTextHypotheses · EP.theorem_9_5_18`; the local structures then have the property needed for the effective integral `Chapter9/StokesTextHypotheses · EP.hloc_hasLUC`. *Dimension* 1 `Chapter15/PerturbedStokesInvariants · SBLocalization.theorem_15_4_3_dim1_hyp`: for Θ of dimension 1 and ω a function, $\int_{\Theta} d\omega$ is the signed count over the finitely many oriented boundary points `Chapter9/StokesDimOne · EP.boundaryBranchedMeasureDim1`, Part IX's Stokes theorem in dimension 1 `Chapter9/StokesDimOne · EP.theorem_9_5_17_dim1`. Together these cover the text's "every sc-differential form of degree $k-1$" for every index $k \geq 1$, $k = m+1$.

Narrower. (a) The orientation is data: the text takes the canonical orientation of Theorem 15.4.1, and with it the induced orientation of $\partial\Theta$ (Definition 9.3.10). Theorem 15.4.1 is formalized only pointwise (§XV.34, gap G.159), so the orientation $\hat{T}$ and its oriented tame structures are hypotheses; "tame" and the dimension $m+1=k$ are carried by these structures, which is how Part IX's Theorem 9.5.17 reads its hypotheses. (b) Sc-smooth partitions of unity on X, a hypothesis of Theorem 9.5.17, inherited; the text's Theorem 15.4.3 does not state it, and Part IX has witnesses for it. (c) The tame germ data of f, inherited (§XV.13). The Fredholm index k of the text enters only through the dimension of the oriented tame structures.

XV.36 Corollary 15.4.4 (2017: 15.2): the invariant and the cobordism argument

The corollary (p. 703) asserts, for $d_X \equiv 0$, paracompact $|X|$, compact $|S_f|$ and an orientation o of f, a well-defined map $\Phi_{(f,o)} : H^*_{\mathrm{dR}}(X) \to \mathbb{R}$ with $\Phi_{(f,o)}([\omega]) = \int_{(\Lambda\circ f,o)} \omega$ for any regular perturbation (N,U,Λ), $\Lambda \circ f$ carrying the canonical orientation; and the effective version under the local unique continuation property. Its proof is left to the reader. Read degree by degree, "well defined" says two things: the integral of an exact form over $(\Lambda \circ f, o)$ vanishes, so the integral descends to cohomology; and a closed form has the same integral over any two regular perturbations. The first is Stokes with

$\partial\Theta = 0$. The second is the cobordism argument: two regular perturbations are joined by a compact oriented cobordism $\tilde{\Theta}$ over $[0,1] \times X$ (Corollary 15.3.10 (3)), and Stokes on $\tilde{\Theta}$ for the pull-back of a closed form. The formalization proves both steps for an abstract cobordism (this subsection) and then builds the cobordism on the cylinder in the text's order (§XV.37).

Oriented regular perturbations. An oriented regular perturbation of dimension $m+1$ `Chapter15/PerturbedStokesInvariants · SBLocalization.OrientedRegularPerturbation` is a regular perturbation (N, U, Λ) of f (Corollary 15.3.10 (1), §XV.31: (N, U) controls compactness, Λ structurable, domain support in U, $N(\Lambda) < 1$, transversal) `Chapter15/RegularPerturbations · SBLocalization.IsRegularPerturbation`, with $\Theta = \Lambda \circ f$ compact and branched, and an orientation $\hat{T}$ of Θ represented by oriented tame structures of dimension $m+1$, the data that Theorem 15.4.1 would provide. Its integral is $\int_{(\Theta,\hat{T})} \omega$ for $\omega \in \Omega^{m+1}_{\mathrm{ep},\infty}(X)$ `Chapter15/PerturbedStokesInvariants · SBLocalization.OrientedRegularPerturbation.integral`, the branched integral of Definition 9.5.6 (1) `Chapter9/TameOpen · EpGroupoid.FormEval.tameBranchedIntegral`.

The statement (narrower) `Chapter15/PerturbedStokesInvariants · SBLocalization.corollary_15_4_4_statement`. For a predicate Can on oriented regular perturbations, standing for "the orientation is the canonical one from (f, o)": (i) for every P with $\mathrm{Can}(P)$ and every $\eta \in \Omega^m_{\mathrm{ep},\infty}(X)$, $\int_P d\eta = 0$; (ii) for any P_0, P_1 with Can and every closed $\omega \in \Omega^{m+1}_{\mathrm{ep},\infty}(X)$, $\int_{P_0} \omega = \int_{P_1} \omega$. Then $\Phi_{(f,o)}([\omega]) = \int_P \omega$ is well defined on H^{m+1}_{dR}, in the degree $m+1 = \dim\Theta$; on the other degrees the text's Φ is 0 by the degree of the integrand, which the formal statement does not spell out. Can is a parameter because the canonical orientation is formalized only pointwise (§XV.34).

Exact forms. *The integral of the zero form vanishes* `Chapter15/PerturbedStokesInvariants · SBLocalization.tameBranchedIntegral_zero`, by linearity of the sheet integrals. *If $\partial X \cap \operatorname{supp}\Theta = \emptyset$, every signed measure on ∂S gives 0 to ∂S* `Chapter15/PerturbedStokesInvariants · SBLocalization.signedMeasure_univ_eq_zero_of_boundary`: $\operatorname{supp}\partial\Theta \subset \partial X \cap \operatorname{supp}\Theta$ `Chapter9/Boundary · EpGroupoid.supp_boundaryTheta_subset`, so the orbit set of $\operatorname{supp}\partial\Theta$ is empty and its whole space is the empty set; in particular the boundary measure vanishes `Chapter15/PerturbedStokesInvariants · SBLocalization.boundaryMeasure_univ_eq_zero`. **Lemma** `Chapter15/PerturbedStokesInvariants · SBLocalization.integral_d_eq_zero_of_degIndex_eq_zero`: if $d_X \equiv 0$ and X has sc-smooth partitions of unity, then $\int_{(\Theta,\hat{T})} d\eta = 0$ for every compact, branched, oriented, tame Θ of dimension $m+1 \geq 2$. *Proof.* Theorem 9.5.17 turns the left side into the boundary measure of ∂S; $\partial X = \{d_X \geq 1\}$ is empty, so the previous fact applies. In dimension 1 the same with the dimension-1 Stokes theorem `Chapter15/PerturbedStokesInvariants · SBLocalization.integral_d_eq_zero_of_degIndex_eq_zero_dim1`.

The cobordism argument `Chapter15/PerturbedStokesInvariants · SBLocalization.integral_eq_of_cobordism`. Let $F : Y \to X$ be an sc-smooth functor between ep-groupoids (in the text, the projection $[0,1] \times X \to X$), Y with sc-smooth partitions of unity, $\tilde{\Theta}$ a compact, branched, oriented, tame ep$^+$-subgroupoid of Y of dimension $m+2$, and I_0, I_1 two functions on $\Omega^{m+1}_{\mathrm{ep},\infty}(X)$ such that for every ω

$$\mu^{\partial\tilde{\Theta}}_{F^*\omega}(\partial\tilde{S}) = I_1(\omega) - I_0(\omega).$$

Then $I_0(\omega) = I_1(\omega)$ for every closed ω. *Proof.* Stokes (Theorem 9.5.17) on Y for the form $F^*\omega$ of degree $m+1$: $\int_{\tilde{\Theta}} dF^*\omega = \mu^{\partial\tilde{\Theta}}_{F^*\omega}(\partial\tilde{S})$. The exterior derivative commutes with the pull-back along a functor, $dF^* = F^*d$ on $\Omega^*_{\mathrm{ep},\infty}$ `Chapter8/EpFormsFunctor · EP.epFormsInftyD_comp_epFormsInftyPullback` (Theorem 11.2.1 (2), the functor case, Part XI; on the direct limit it is checked level by level from the same identity for forms of a fixed level). So $dF^*\omega = F^*d\omega = 0$, the left side is the integral of the zero form, 0, and

$I_1(\omega) - I_0(\omega) = 0$. The text's form, with $\partial\tilde{\Theta} = \Theta_1 \sqcup -\Theta_0$, is the case $I_i = \int_{\Theta_i}$; the lemma separates the analytic content (Stokes and $dF^* = F^*d$) from the identification of the boundary, which is §XV.37.

Cobordant perturbations `Chapter15/PerturbedStokesInvariants · SBLocalization.OrientedRegularPerturbation.HasOrientedCobordism`. P_0 and P_1 are joined by an oriented compact cobordism if there are Y, F, $\tilde{\Theta}$ as in the lemma with $\mu^{\partial\tilde{\Theta}}_{F^*\omega}(\partial\tilde{S}) = \int_{P_1}\omega - \int_{P_0}\omega$ for all ω. **Corollary 15.4.4** (narrower) `Chapter15/PerturbedStokesInvariants · SBLocalization.corollary_15_4_4_hyp`: for $d_X \equiv 0$ and X with sc-smooth partitions of unity, in every dimension $m+1 \geq 1$, the statement holds for every Can whose members are pairwise cobordant. *Proof.* (i) is the exact-form lemma, split by $m = 0$ (dimension 1) or $m \geq 1$. (ii): the cobordism between P_0 and P_1 and the cobordism argument with $I_i = \int_{P_i}$.

The added hypothesis, that any two perturbations of the class are cobordant, is not derived here; on the cylinder it is reduced to the oriented end identities (§XV.37). It is satisfiable with a nonempty class: every oriented regular perturbation is cobordant to itself `Chapter15/PerturbedStokesInvariants · SBLocalization.OrientedRegularPerturbation.hasOrientedCobordism_refl`, with $Y = X$, F the identity and $\tilde{\Theta} = 0$, which is branched `Chapter9/Basic · EpGroupoid.isBranchedEpSubgroupoid_zero`, compact (its support is empty) and oriented by the zero lift `Chapter9/OrientationBasic · EpGroupoid.isOrientation_zero`, with vanishing boundary measure. This witness is **weak**: it shows that the hypothesis can hold, not that it holds for two different perturbations; no oriented regular perturbation with nonempty support exists in the project. *Further hypotheses*: partitions of unity on X, for Stokes; the paracompactness of $|X|$, which the corollary assumes, is not used in this form (it enters through the cylinder, §XV.37).

XV.37 Corollary 15.4.4 on the cylinder: the ends, the boundary measure, the effective version; Remark 15.4.5

The text's argument, "in view of Corollary 15.3.10", has four steps: (a) two regular perturbations (N^i, U^i, Λ^i) of f with $\Theta_i = \Lambda^i \circ f$; (b) Theorem 15.3.9 on $[0,1] \times X$ gives $\tilde{\Lambda}$ with $\tilde{\Lambda} = \Lambda^i$ over $\{i\} \times X$, and $\tilde{\Theta} = \tilde{\Lambda} \circ \tilde{f}$ is a compact cobordism between Θ_0 and Θ_1 (Corollary 15.3.10 (3)); (c) $\tilde{\Theta}$ carries the canonical orientation from $(\tilde{f}, \tilde{o})$, and with the boundary orientation of Definition 9.3.10, $\partial\tilde{\Theta} = \Theta_1 \sqcup -\Theta_0$; (d) Stokes on $\tilde{\Theta}$ (§XV.36). The formalization follows this order. Proved: (a), (b) with Theorem 15.3.9 in its charged form (§§XV.27–XV.33), the restriction of $\tilde{\Theta}$ to the ends as sets and as orbits, the splitting of the boundary measure over the two ends, and (d). Step (c), the oriented identification of each end, is a hypothesis (gap G.182).

Throughout, the cylinder is $[0,1] \times X$, the case $n = 1$ of $[0,1]^n \times X$ (§XV.30), with the pulled-back bundle and $\tilde{f}(t,x) = (t, f(x))$; $\tilde{\Lambda}$ is any function on the cylinder bundle with $\tilde{\Lambda}(w) = \Lambda^0(w_2)$ over $t = 0$ and $\tilde{\Lambda}(w) = \Lambda^1(w_2)$ over $t = 1$, w_2 the W-component.

$\tilde{\Theta}$ on the ends (same; V15.48). Over $t = 0$, $\tilde{\Lambda}(\tilde{f}(t,x)) = \Lambda^0(f(x))$ `Chapter15/CylinderEnds · SBLocalization.theta_cyl_of_time_zero`, and over $t = 1$, $\Lambda^1(f(x))$ `Chapter15/CylinderEnds · SBLocalization.theta_cyl_of_time_one`: the W-component of $\tilde{f}(t,x)$ is $f(x)$. Hence $\tilde{\Theta} \circ i_0 = \Theta_0$ and $\tilde{\Theta} \circ i_1 = \Theta_1$ for the inclusion functors $i_q : X \to [0,1] \times X$, $x \mapsto (q,x)$ (§XV.30) `Chapter15/CylinderEnds · SBLocalization.theta_cubeIncl_zero Chapter15/CylinderEnds · SBLocalization.theta_cubeIncl_one`, the text's "restricts to $\{i\} \times X = X$ as Θ_i" (p. 700). **The boundary part of the support** `Chapter15/CylinderEnds · SBLocalization.mem_boundary_inter_supp_cyl_iff`: for $d_X \equiv 0$, $(t,x) \in \partial([0,1] \times X) \cap \operatorname{supp}\tilde{\Theta}$ iff $t = 0$ and $x \in \operatorname{supp}\Theta_0$, or $t = 1$ and $x \in \operatorname{supp}\Theta_1$. *Proof.* $d_X \equiv 0$ makes X tame (§XV.30) `Chapter5/DegeneracyZeroTame · EpGroupoid.isTame_of_`

degIndex_eq_zero, and then $\partial([0,1]\times X)=\{0,1\}\times X$ Chapter15/RegularPerturbations · SBLocalization.mem_boundary_cubeSEP_iff; on each end the value of $\tilde\Theta$ is that of Θ_i, by the two identities above.

The ends on orbit spaces. The orbit space of the cylinder is $[0,1]\times|X|$ (the homeomorphism of §XV.30) Chapter15/Cylinder · EpGroupoid.cubeOrbitHomeomorph. Its time coordinate, $|(t,x)|\mapsto t$, is defined through the inverse of this homeomorphism Chapter15/CylinderEnds · EpGroupoid.cylOrbitTime, takes the value t on the orbit of (t,x) Chapter15/CylinderEnds · EpGroupoid.cylOrbitTime_π and is continuous Chapter15/CylinderEnds · EpGroupoid.continuous_cylOrbitTime. For Θ on the cylinder, the *end at time i* of $\partial S=|\operatorname{supp}\partial\Theta|$ is the set of its points of time i Chapter15/CylinderEnds · EpGroupoid.cylEnd. It is closed, as the preimage of a point under a continuous map Chapter15/CylinderEnds · EpGroupoid.isClosed_cylEnd, hence Borel, hence in the σ-algebra $L(\partial S)$ of Definition 9.5.14, which contains the Borel sets Chapter9/BoundaryNullSigmaAlgebra · EpGroupoid.borel_le_lebesgueSigmaBoundaryH Chapter15/CylinderEnds · EpGroupoid.measurableSet_cylEnd. The map $|(i,x)|\mapsto|x|$ from the end at time i to $|X|$ Chapter15/CylinderEnds · EpGroupoid.cylEndMap is $|x|$ on the orbit of (i,x) Chapter15/CylinderEnds · EpGroupoid.cylEndMap_π, continuous Chapter15/CylinderEnds · EpGroupoid.continuous_cylEndMap and injective Chapter15/CylinderEnds · EpGroupoid.injective_cylEndMap. *Proof of injectivity.* Two points of the end at time i come from objects (q,x), (q',x') of the support with the same time i, so $q=q'$ (the cube $[0,1]^1$ has one coordinate); if $|x|=|x'|$, the two objects are isomorphic in $[0,1]\times X$, because two objects of the product are isomorphic iff their cube coordinates agree and their X-components are isomorphic (§XV.30), and so the two orbits agree. For $d_X\equiv 0$ the end at time i of $|\operatorname{supp}\partial\tilde\Theta|$ maps into $|\operatorname{supp}\Theta_i|$ Chapter15/CylinderEnds · SBLocalization.cylEndMap_mem_orbitSupp_zero Chapter15/CylinderEnds · SBLocalization.cylEndMap_mem_orbitSupp_one: a point of $\operatorname{supp}\partial\tilde\Theta$ lies in $\partial([0,1]\times X)\cap\operatorname{supp}\tilde\Theta$ (Definition 9.2.16), so by the description of the boundary part of the support its X-component lies in $\operatorname{supp}\Theta_i$ for its time i; the other end is excluded because $0\neq 1$.

The boundary measure splits Chapter15/CylinderEnds · SBLocalization.boundaryMeasure_cyl_univ. For $d_X\equiv 0$ and any compact, branched, oriented, tame $\tilde\Theta$ of dimension $m+2$ on the cylinder, $\mu_\omega^{\partial\tilde\Theta}(\partial S)=\mu_\omega^{\partial\tilde\Theta}(\text{end }0)+\mu_\omega^{\partial\tilde\Theta}(\text{end }1)$; the same for the effective boundary measure Chapter15/CylinderEnds · SBLocalization.boundaryMeasureEff_cyl_univ. *Proof.* A general lemma Chapter15/CylinderEnds · EpGroupoid.signedMeasure_univ_eq_cylEnds: if every boundary object of the cylinder has time 0 or 1, then for every σ-algebra on ∂S containing the Borel sets and every signed measure μ on it, $\mu(\partial S)=\mu(\text{end }0)+\mu(\text{end }1)$. Every point of ∂S has time 0 or 1 Chapter15/CylinderEnds · EpGroupoid.cylOrbitTime_eq_zero_or_one, because it is the orbit of a point of $\operatorname{supp}\partial\Theta\subset\partial([0,1]\times X)$; so ∂S is the union of the two ends, which are disjoint and measurable, and μ is additive on them. For $d_X\equiv 0$ the boundary objects have time 0 or 1 Chapter15/CylinderEnds · SBLocalization.boundary_cyl_time, and the boundary measures of Theorems 9.5.15 and 9.5.16 live on $L(\partial S)$, which contains the Borel sets.

Step (c) as a proposition. *The end identities* Chapter15/CylinderCobordism · SBLocalization.IsCylinderBoundaryOf: for oriented regular perturbations P_0, P_1 of dimension $m+1$ and a compact, branched, oriented, tame $\tilde\Theta$ of dimension $m+2$ on the cylinder, for every $\omega\in\Omega^{m+1}_{\mathrm{ep},\infty}(X)$,

$$\mu^{\partial\tilde\Theta}_{pr^*\omega}(\text{end }1)=\int_{P_1}\omega,\qquad \mu^{\partial\tilde\Theta}_{pr^*\omega}(\text{end }0)=-\int_{P_0}\omega,$$

\$pr = \$ the projection functor to X (§XV.30) Chapter15/CubeEp · EpGroupoid.cubeProj. This is the text's "$\partial\tilde\Theta=\Theta_1\sqcup-\Theta_0$", read on the level of the boundary measure, which is what Stokes uses: with the outward normal first (Definition 9.3.10), the outward normal is $+\partial_t$ at $t=1$ and $-\partial_t$ at $t=0$, whence the sign. *The orientation statement* Chapter15/CylinderCobordism · SBLocalization.CylinderOrientationStatement: every

$\tilde\Lambda$ that step (b) can produce, that is, every regular perturbation of $\tilde f$ for the interpolated pair $(\tilde N, \tilde U)$ of Corollary 15.3.10 (2) (§XV.31) Chapter15/CubeAuxNorm · SEP.interpAuxNorm Chapter15/CubeAuxNorm · SEP.interpSet with $\tilde\Lambda = \Lambda^i$ over $t = i$ and $\tilde\Theta$ compact and branched, carries an orientation by oriented tame structures of dimension $m + 2$ with the end identities. In the text this orientation is the canonical one from $(\tilde f, \tilde o)$; the statement asks only for the properties of it that the argument uses.

The cobordism from the end identities Chapter15/CylinderCobordism · SBLocalization.hasOrientedCobordism_of_cylinder: for $d_X \equiv 0$ and the cylinder with sc-smooth partitions of unity, a $\tilde\Theta$ with the end identities joins P_0 and P_1 in the sense of §XV.36, with $Y = [0,1] \times X$ and $F = pr$. *Proof.* $\mu^{\partial\tilde\Theta}_{pr^*\omega}(\partial S)$ is the sum over the two ends, and the end identities make it $\int_{P_1}\omega - \int_{P_0}\omega$. *Partitions of unity on the cylinder* Chapter15/CylinderCobordism · SBLocalization.hasScPartitionsOfUnity_cyl: in the ep-groupoid sense of Definition 7.5.5, from Theorem 7.5.7 Chapter7/PartitionsOfUnity · EpGroupoid.theorem_7_5_7, given the paracompactness of the orbit space of the cylinder, which follows from that of $|X|$ Chapter15/Cylinder · EpGroupoid.hasParacompactOrbitSpace_cubeProd, and partitions of unity on the object M-polyfold of the cylinder, which follow from those of X (§XV.32) Chapter15/CylinderPartitions · SBLocalization.admitsScPartitionsOfUnity_cubeSEP.

Steps (b) and (c) together Chapter15/CylinderCobordism · SBLocalization.hasOrientedCobordism_cylinder_hyp: for $d_X \equiv 0$, $|X|$ paracompact, f sc-Fredholm with tame germ data and compact $|S_f|$, if the charged Theorem 15.3.9 holds on the cylinder, the cylinder bundle has tame strong bundle charts at every object, its object M-polyfold has sc-smooth partitions of unity, the glued boundary data of Λ^0, Λ^1 are structurable over the boundary and satisfy the face condition (§XV.32), and step (c) holds, then P_0 and P_1 are cobordant. *Proof.* Corollary 15.3.10 (3) in its charged form (§XV.33) Chapter15/ChargedExtensionCylinder · SBLocalization.corollary_15_3_10_3_charged produces $\tilde\Lambda$: a regular perturbation of $\tilde f$ for $(\tilde N, \tilde U)$, equal to Λ^i over $t = i$, with $\tilde\Theta$ compact and branched. Step (c) gives the orientation and the end identities, and the previous paragraph the cobordism.

Corollary 15.4.4 along the text's argument (narrower) Chapter15/CylinderCobordism · SBLocalization.corollary_15_4_4_cylinder_hyp: for $d_X \equiv 0$, $|X|$ paracompact, sc-smooth partitions of unity on X and on the object M-polyfold of the cylinder, f sc-Fredholm with tame germ data and compact $|S_f|$, and a class Can: if the charged Theorem 15.3.9 holds on the cylinder, the cylinder bundle has tame strong bundle charts, and for any two members of Can the glued data are structurable with the face condition and step (c) holds, then the statement of §XV.36 holds. *Proof.* Corollary 15.4.4 from cobordisms (§XV.36), the cobordisms from the previous paragraph. *With Theorem 15.3.9 on the cylinder reduced* Chapter15/CylinderCobordism · SBLocalization.corollary_15_4_4_cylinder_of_rel: the charged Theorem 15.3.9 on the cylinder follows from the relative statement of steps (c)–(d) there (§XV.29) Chapter15/ChargedExtensionFibres · SBLocalization.theorem_15_3_9_charged_hyp Chapter15/TransversalExtension · SBLocalization.theorem_15_3_7_relative_statement, so the corollary rests on that relative statement in place of the theorem.

Narrower. Formalized in the text's order: the two regular perturbations, the cylinder perturbation from the charged Theorem 15.3.9, its restriction to the ends, the splitting of the boundary measure, and Stokes with $dF^* = F^*d$. The hypotheses are: (1) step (c), the oriented end identities (gap G.182), which contain the weights on the ends ($\partial\tilde\Theta(i,x) = \Theta_i(x)$, gap G.190; proved here are the values of $\tilde\Theta$, the support and the injectivity of the end maps, not that the end maps are onto $|\operatorname{supp}\Theta_i|$ nor the weights of $\partial\tilde\Theta$) and the canonical orientation on the cylinder (Theorem 15.4.1, gap G.159), so Can stays a parameter; (2) the charged Theorem 15.3.9 on the cylinder, hence the relative local families there (gap G.178); (3) tame strong bundle charts on the cylinder (gap G.189); (4) the structurability of the glued data, proved given

that lifted sc⁺-sections are sc⁺ on the faces (gap G.193, §XV.32), and their face condition (gap G.180); (5) partitions of unity on X, used for Stokes and for those of the cylinder, which the corollary does not state. The paracompactness of $|X|$, which the corollary assumes, is used for the cylinder's partitions of unity. *Witnesses.* Step (c) has **no witness in the non-degenerate case**: the project has no oriented regular perturbation with nonempty support. The remaining hypotheses have the weak witnesses listed with §§XV.29, XV.32–XV.33 (on $\mathbb{R}^n \times \mathbb{R}^0 \to \mathbb{R}^n$, no boundary, zero fibres); tame strong bundle charts on the cylinder have none of their own.

The effective version (narrower; V15.49). *Definitions*: the effective integral $\oint_P \omega$ over an oriented regular perturbation, for X with the local unique continuation property (Definition 9.5.6 (2)) `Chapter15/CylinderCobordism · SBLocalization.OrientedRegularPerturbation.integralEff` `Chapter9/TameOpen · EpGroupoid.FormEval.tameBranchedIntegralEff`, and effective cobordisms, as in §XV.36 with Y having the local unique continuation property and the effective boundary measure `Chapter15/CylinderCobordism · SBLocalization.OrientedRegularPerturbation.HasOrientedCobordismEff`. *The statement* `Chapter15/CylinderCobordism · SBLocalization.corollary_15_4_4_eff_statement`: exact forms have effective integral 0 over every member of Can, and closed forms have the same effective integral over any two, so $\Phi^{\mathrm{eff}}_{(f,o)}([\omega]) = \oint_{(\Lambda\circ f,o)} \omega$ is well defined in degree $m+1$. *The lemmas*, as in §XV.36: the effective integral of the zero form vanishes `Chapter15/CylinderCobordism · SBLocalization.tameBranchedIntegralEff_zero`; the cobordism argument with Theorem 9.5.18 on Y in place of Theorem 9.5.17 `Chapter15/CylinderCobordism · SBLocalization.integralEff_eq_of_cobordism`; and exact forms `Chapter15/CylinderCobordism · SBLocalization.integralEff_d_eq_zero_of_degIndex_eq_zero`, for $d_X \equiv 0$, by Theorem 9.5.18 and, in dimension 1, its dimension-1 form `Chapter9/EffectiveDimOneLUC · EP.theorem_9_5_18_dim1_isLUC`, the boundary measure vanishing because $\partial X = \emptyset$. *Proof of the statement* `Chapter15/CylinderCobordism · SBLocalization.corollary_15_4_4_eff_hyp`, for $d_X \equiv 0$, partitions of unity and the local unique continuation property on X, and pairwise effective cobordisms: the two lemmas, in every dimension $m+1 \geq 1$. The cobordism hypothesis is satisfiable with a nonempty class `Chapter15/CylinderCobordism · SBLocalization.OrientedRegularPerturbation.hasOrientedCobordismEff_refl` (self-cobordism by $\tilde{\Theta} = 0$; **weak**, as in §XV.36).

On the cylinder: the effective end identities `Chapter15/CylinderCobordism · SBLocalization.IsCylinderBoundaryEffOf`, with the effective boundary measure and $\oint_{P_i}$, give an effective cobordism `Chapter15/CylinderCobordism · SBLocalization.hasOrientedCobordismEff_of_cylinder` through the splitting of the effective boundary measure; step (c) in effective form `Chapter15/CylinderCobordism · SBLocalization.CylinderOrientationEffStatement`; and the corollary along the text's argument `Chapter15/CylinderCobordism · SBLocalization.corollary_15_4_4_eff_cylinder_hyp`, from the charged Theorem 15.3.9 on the cylinder and the hypotheses of the non-effective form, with the local unique continuation property on X and on $[0,1]\times X$. The latter presumably follows from that on X, natural representations of the cylinder at (t,x) being products of those of X at x with the trivial groupoid of $[0,1]$; it is not derived (gap G.191) and has no witness.

Remark 15.4.5 (nothing to formalize). The remark mentions another route to invariants, triangulating the weighted solution set into a rational chain, and says it is not carried out; there is nothing to formalize.

XV.38 What is not formalized

The open gaps of the chapter, with what is proved of each, what is missing, and an estimate of the Lean it needs.

- **Gap G.159** (formalized in part): Theorem 15.4.1 and Definition 15.4.2 as an orientation of $\Theta = \Lambda \circ f$. Proved at single points in Part I's chart reading: $(f - s_i)'(y) \in \mathrm{Lin}(f, y)$, the existence, formula and uniqueness of the canonical lift, its independence of the local structure, and the kernel orientations $o_{i,y}$ (§XV.34). Missing: (a) the tangent spaces of the branches $M_i = \{f = s_i\}$ in good position are the kernels of $(f - s_i)'(y)$ in the chart, 150–250 lines; (b) the continuity of $y \mapsto o_{i,y}$ along M_i as an orientation of a submanifold in Chapter 9's sense, with a bridge from Part I's ray orientations to frames, 300–450; (c) naturality under morphisms, 150–250; (d) the assembly into an orientation of Θ with independent tangent sums, after which the class of canonically oriented perturbations that Corollary 15.4.4 takes as a parameter, and the orientation that Theorem 15.4.3 takes as data, are defined; 150–250. Together 750–1,200 lines.
- **Gap G.160** (formalized in part): the products remark after Definition 15.3.3 and Remark 15.3.4. Formalized: product ep-groupoids, the product strong bundle and the product over $X \times X'$ with $\mu \times \mu'$, products of sections and section functors, sc-smooth and sc$^+$, products of strong bundle maps, the level 1 of the product, and $\max(N, N')$ as an auxiliary norm (§XV.19). Missing: (c) $f \times f'$ sc-Fredholm with tame germ data, for which Part I has only the cube parameter case: products of filling germs, of basic germs after reordering coordinates, and of the regularizing property, 300–500 lines; (d) $\Lambda \times \Lambda'$ as an sc$^+$-multisection, from products of local section structures with weights $\sigma_i \sigma'_j$, its norm max for $N \times N'$, admissibility for $(N \times N', U \times U')$ and the domain-support inclusion of Remark 15.3.4, 150–300 lines. Together 450–800 lines.
- **Gap G.162** (closed for Theorem 15.3.7): what remains is Theorem 15.3.9 and Corollary 15.3.10 (3), that is, the gaps G.178–G.180, G.189 and G.193 below. Corollary 15.3.10 (1) is proved from Theorem 15.3.7 for paracompact $|X|$ (§XV.31), though the composite is not stated as one declaration.
- **Gap G.178**: Theorem 15.3.9, steps (c)–(d), the relative local families, the one proposition from which the charged Theorem 15.3.9 is proved (§XV.29). Proved: everything else in steps (c)–(d), the relative Sard and compactness steps included, and the trivial families where the support meets only ∂X. Missing: (a) seeds at interior support points: one family making all $(f - s_a^0)'(x)$ onto at once, by the bridge of §XV.24 applied to each $f - s_a^0$ and complements of the finitely many cokernels, then openness for each pair of branches, and a seed family with domain support in a small neighbourhood avoiding ∂X; (b) openness at boundary support points: the family vanishes near x, so the reduced surjectivity of (f, Λ_0) at x must persist near x, from Part I's openness with $\ell = 0$ and the passage from Part I's general position to reduced surjectivity, about 60–100 lines. Together 400–700 lines.
- **Gap G.179**: the face condition of Theorem 15.3.9 does not depend on the extension. It is asked for every sc$^+$ extension of the boundary data (§XV.27). Missing: (a) the restriction of $(f - s_i)'(x)$ to $T_x^R X$ depends only on s_i on the faces through x, a germ argument in a tame chart, about 80 lines; (b) two sc$^+$ extensions have local representations whose branches agree on the faces up to reindexing, a statement of the kind of Theorem 15.1.1 on faces, with crossing branches and the charts of boundary symmetric structures, 170–320 lines; (b) needs the non-empty index sets that charging gives. Together 250–400 lines.
- **Gap G.180**: Corollary 15.3.10 (3), the face condition of the glued boundary data on $\{0, 1\} \times X$. Their values, boundary domain support, norm and charging are proved, and their structurability given G.193 (§XV.32). Missing: restriction of sc$^+$ extensions to the slices $\{i\} \times X$, $T^R_{(i,x)}([0, 1] \times X) = \{0\} \times T_x X$ when $d_X \equiv 0$, and the transversality of (f, Λ^i); 150–250 lines after G.179 (b). Its only witness has zero fibres.
- **Gap G.182**: Corollary 15.4.4, the oriented end identities $\mu^{\partial\tilde{\Theta}}_{pr^*\omega}(\text{end } i) = \pm \int_{\Theta_i} \omega$ on the cylinder, assumed through the orientation statement of step (c) (§XV.37). Missing: (a) the weights on the

ends, gap G.190; (b) oriented tame structures of $\tilde{\Theta}$ at (i,x) whose boundary sheets are $\{i\}\times M_j$, with the weights and isotropy of Θ_i; (c) the boundary orientation of $\{i\}\times M_j$ inside $\tilde{M}_j$, outer normal first (Definition 9.3.10), equal to $(-1)^{i+1}$ times the canonical orientation of M_j, Part I's sign bookkeeping of Theorem 6.7.1 for the kernel of $(\tilde{f}-\tilde{s})'$ with ∂_t, which needs Theorem 15.4.1 on the cylinder (G.159); (d) the sheet integral of $pr^*\omega$ over $\{i\}\times M$ equals that of ω over M; (e) the transfer of measurability along the end maps and the uniqueness of Theorem 9.5.4 for the push-forward. 1,200–2,200 lines, plus (c) after G.159; a non-degenerate witness, an oriented regular perturbation with nonempty support, 300–600 lines more.

- **Gap G.189**: tame strong bundle charts on $[0,1]\times X$, a hypothesis of Corollaries 15.3.10 (3) and 15.4.4 on the cylinder (§§XV.33, XV.37), without a witness. The cylinder bundle is a pull-back whose atlas contains the charts over the identity of a cube-times-chart model; missing is that the products of a tame strong bundle chart of W with the tame charts of the cube are modelled on relatively open subsets of a partial quadrant. 80–250 lines.
- **Gap G.190**: the weights on the ends of the cylinder, $\partial\tilde{\Theta}(i,x)=\Theta_i(x)$. Proved: $\tilde{\Theta}(i,x)=\Theta_i(x)$, the boundary part of the support is the two ends, and each end maps injectively into $|\operatorname{supp}\Theta_i|$ (§XV.37). Missing: every local sheet $\tilde{M}_j$ through (i,x) has (i,x) on its boundary. $T\tilde{M}_j$ has dimension $k+1$, and its intersection with $T^R=\{0\}\times T_xX$ is the kernel of an onto operator of index k by the face condition, so $T\tilde{M}_j\not\subseteq T^R$ and Remark 9.2.14 applies; then the end map is onto. 300–500 lines.
- **Gap G.191**: the local unique continuation property on $[0,1]\times X$, a hypothesis of the effective cylinder forms of Corollary 15.4.4 (§XV.37): natural representations of the cylinder at (t,x) from those of X at x, as a product with the trivial groupoid of $[0,1]$. 80–150 lines.
- **Gap G.193**: lifted sc$^+$-sections are sc$^+$ on the faces of $[0,1]\times X$, the statement from which the glued data are structurable (§XV.32). Missing: a local form of Part I's lemma on sc$^+$-sections in charts, for charts whose domain is not inside the open set, 80–120 lines; the lift $(q,y)\mapsto((q,y),s(y))$ is sc$^+$ on $[0,1]\times U$, the level-$(0,1)$ analogue of Part I's pull-back of sc-smooth sections, 120–200; the face lemma of Chapter 14 (Part XIV) for an open set in place of X, 40–80. Together 250–400 lines. It has no witness: a witness would be the statement for all tame charts of the cube, which is the general proof.

Not formalized, and not needed. The functoriality of $\varphi\mapsto\varphi_*$ on GrF, $(\psi\varphi)_*=\psi_*\varphi_*$ and $1_*=\mathrm{id}$, and $\mathrm{GrF}(X)$ as a category over X, which the text uses without a numbered statement; about 60–100 lines from Chapter 7, and not used by the functor property (§XV.9). The independence of the sc-structures of T_zO and K_z from the chart, not used since the sc-Fredholm property holds in every chart (§XV.11). "Tame" in the conclusions of Theorem 15.3.9 and Corollary 15.3.10 (3): the formal conclusions say branched and compact; the perturbations built are in general position, so the tame form of the "in particular" of Theorem 15.3.7 (§XV.21) applies to them, but the combination is not stated.

Hypotheses without a non-degenerate witness. The relative local families of Theorem 15.3.9 and the charged theorem itself are witnessed only on $\mathbb{R}^n\times\mathbb{R}^0\to\mathbb{R}^n$, with no boundary and zero fibres (§XV.29); the face condition of the glued data only with zero fibres (§XV.33); the lifted sections on faces (G.193), the tame bundle charts of the cylinder (G.189) and the local unique continuation property on the cylinder (G.191) have none; the orientation statement on the cylinder (G.182) has none with nonempty support, and the cobordism hypothesis of Corollary 15.4.4 only the self-cobordism with $\tilde{\Theta}=0$ (§§XV.36, XV.37). Every other hypothesis of the Part has a witness, named in its subsection.

Prose. Remarks 15.2.6, 15.3.2, 15.3.11 and 15.4.5 have nothing to formalize; Remark 15.3.8 holds in the

form of §XV.26.

XV.39 What the formalization taught us

§15.1 is topology plus Part I's chain rule. The proof of Theorem 15.1.1 is a statement about finitely many continuous maps and their germs, and it holds in that generality: two finite families of branches with the same weighted count of every value at every point have the same formal sums of (value, germ invariant) pairs at every point, as soon as the germ invariants vary continuously (§XV.7). Lemmas 15.1.4, 15.1.5, Proposition 15.1.3 and Remark 15.1.6 are pure topology, and Lemma 15.1.5 needs only the observation that two continuous maps into a Hausdorff space differ on an open set, so it is proved pair by pair without Lemma 15.1.4 (§XV.5). Written this way, two places of the text needed a reading. The derivative of an sc¹ map is continuous only on level 1, and there pointwise; so the argument runs in the level-1 topology, where it holds equally, and the text's "weak topology" is pointwise convergence. And the final display of the text sums over all branches, as if every $s_i(0)$ equalled $f(0)$; comparing pairs (value, derivative) for all branches and selecting the value $f(0)$ at the end avoids this. Separating the two families together, rather than their union with halved weights, gives the comparison in one step, and it lets x_0 itself serve as a separated point. So Proposition 15.1.3, which asks for $x_k \neq 0$ converging to 0 and does not hold as we read it at an isolated point, is not needed. The step "without loss of generality $X = O$" is the independence of the intrinsic operator $(f - s)'(x)$ from the chart, which Part I's chain rule gives at a zero of $f - s$ made a global section (§XV.7). The functor property, for which the text gives no argument, is the same chain rule once more: a local structure near $s(\varphi)$ is carried to one near $t(\varphi)$ by the local strong bundle isomorphism of the sheet of φ, and in the carried chart $T\varphi$ is the identity on chart vectors, so the intrinsic operators are conjugate by $\mu(\varphi, \cdot)$ (§XV.9).

§15.2 is Part I branch by branch, and so inherits Part I's hypothesis. A local sc⁺-section on O is a global sc⁺-section of $W|_O$, and $(f - s_i)|_O$ is an sc-Fredholm section there, so Part I's Theorems 3.1.18, 3.1.26 and 3.6.8 apply to each branch (§XV.10). This gives the sc-Fredholm summands of $T(f, \Lambda)$ in the chart reading, the local solution sets, their tameness, and good position along them. The price is Part I's tame germ data, without which Theorem 3.6.8 does not hold as we read it; it is inherited, not new, and it is the same hypothesis that §12.5 and the cylinder carry. Definition 15.2.1 asks for less than it says: "nonzero" and "sc-Fredholm" are automatic, so transversality is the surjectivity of every summand (§XV.12). The proof of Theorem 15.2.2, which writes $f(x) = s_i(x)$ for all i, presumably means the branches through $f(x)$; the others have empty solution sets near x (§XV.13). "The ep-groupoid $U(x)$" is the translation groupoid $G_x \ltimes U(x)$, and on it the paracompactness of the support, which Definition 9.1.2 (1) asks of a branched ep⁺-subgroupoid since 2021, is automatic, its orbit map being closed with finite fibres; on X it is a hypothesis that the remarks do not address (§XV.14).

General position is Part I's general position of each branch. On $T^R_x X$ the intrinsic operator of a branch is the derivative of the branch in a transported chart of $W|_O$, so surjectivity there is Part I's general position of $(f - s_i)|_O$; that gives good position by Part I and persists near x. This is why Remark 15.3.6 holds at every point of the support and not only at ∂X, and why it needs no $d_X = 0$ (§§XV.16, XV.20). General position at a point is invariant under morphisms, which the text uses silently when it passes to saturations "by equivariance" (§XV.25).

The existence theorems separate into an assembly and Part I. The assembly of Theorem 15.3.7 is finite covers of $|S_f|$, sums of linear families, the bounds $N(\Lambda \oplus \Lambda') \leq N(\Lambda) + N(\Lambda')$ and on domain supports that the text uses silently, and a small parameter off a null set (§XV.22). The local families are Part XIII's

atomic multisections built from seeds, linear in the parameter and carried along morphisms (§XV.23). Parametric transversality is Part I's local Sard step branch by branch: in a tame chart a branch of Λ_t is the slice at t of a Part I parametrized section, and (15.1) for the branch is Part I's general position of that section at $(0, x)$ (§XV.25). The one bridge the text takes for granted is between (15.1), which uses $T^R_x X$, and Part I's conditions (i)–(ii), which use the full tangent space; in a tame chart centred at the zero the two are equivalent by two lines of linear algebra in each direction, and the text's appeal to the implicit function theorem for the openness of (15.1) is Part I's openness of general position on the product with $\mathbb{R}^\ell$ (§XV.24). "Structurable" contains a good system, so the addendum of Theorem 15.3.7 needs one; (1)–(4) do not, with the sums of Definition 13.2.9 in place of structurable ones, which is Remark 15.3.8 (§XV.26).

Boundary data must charge the boundary. Theorem 15.3.9 is Theorem 14.1.9 followed by Theorem 15.3.7 relative to the boundary. Stated with the index sets of the formal Definition 14.1.3, which admits empty ones, it fails with boundary: the zero function with empty index sets is structurable over ∂X, and no structurable extension vanishes there (§XV.27). The text's boundary multisection has non-empty index sets; with it, the charged statement, the theorem is proved from one open proposition. A witness on a space without boundary could not reveal this, which is why every hypothesis here is asked for a witness in the non-degenerate case. Step (a), the cut-off h_0, uses the upper semicontinuity of $N(\Lambda)$ along ∂X, which holds when the bundle has tame charts at every object and which the text uses without comment (§XV.28). Steps (c)–(d) are Theorem 15.3.7 with the operators of $T(f, \Lambda_0)$ in place of those of $T(f, 0)$, and the parametric part carries over branch by branch (§XV.29).

The cylinder needs more than the text says. The product with $[0, 1]$ is built as the product with Part I's cube, whose parametrized Fredholm theory is available; $d_X \equiv 0$ makes X tame, a step the text takes without comment (§XV.30); the auxiliary norm of Corollary 15.3.10 (2), which the text does not give, is the interpolation $\max(\alpha(t)N^0, \beta(t)N^1)$ (§XV.31). The partitions of unity of $[0, 1] \times X$ are a product construction, $\sum_x \rho_x(y) g_x(q)$, and the structurability of the glued boundary data comes from lifting the structures of the Λ^i along $[0, 1] \times X \to X$, where two continuous lifts that agree at one point agree on a connected neighbourhood (§XV.32). The text's proof does not say how the face condition of the glued data is checked; presumably from the transversality of (f, Λ^i), since $T^R_{(i,x)}([0, 1] \times X) = \{0\} \times T_x X$ when $d_X \equiv 0$ (§XV.33).

In §15.4 the argument is short and the data are hard. The canonical lift is pointwise linear algebra once the operators $(f - s_i)'(y)$ are seen to be in Part I's $\mathrm{Lin}(f, y)$, because $f - s_i$ differs from f by an sc^+ term (§XV.34). The cobordism argument for the invariants is Stokes' theorem with $dF^* = F^* d$ (§XV.36), and Theorem 15.4.3 does not use the tameness of X, good position carrying what is needed at boundary points (§XV.35). What is hard is the data the argument takes: the continuity of the kernel orientations along the branches, and on the cylinder the weights and signs on the ends, where Part I's orientation bookkeeping has to meet Chapter 9's boundary orientation (§XV.37, gaps G.159, G.182, G.190).

Part XVI. Polyfolds (HWZ Chapter 16, §§16.1–16.6)

Chapter 16 (Springer 2021, pp. 705–740; 2017 numbers in parentheses) passes from ep-groupoids to polyfolds. A polyfold is a topological space Z together with an equivalence class of ep-groupoid structures on it, and every notion of the earlier chapters (bump functions, partitions of unity, the degeneracy index, tameness, the tangent, sc-differential forms, strong bundles, auxiliary norms, sections, branched ep$^+$-subgroupoids, sc$^+$-multisections, sc-Fredholm sections, orientations and the invariants of Chapter 15) is carried to the class. The method is uniform: a notion of a polyfold is a notion of one structure in the class, and a theorem of invariance under equivalences of ep-groupoids, or under generalized isomorphisms, shows that it does not depend on the structure. §16.1 defines polyfold structures, their equivalence and polyfolds (Definitions 16.1.1–16.1.3 (2017: Definitions 16.1–16.3)), shows that bump functions and partitions of unity are invariant (Proposition 16.1.4, Definition 16.1.5 (2017: Proposition 16.2, Definition 16.4)), defines the maps between polyfolds (Definitions 16.1.6, 16.1.8, 16.1.10, 16.1.11, Remarks 16.1.7, 16.1.9 (2017: Definitions 16.5–16.8, Remarks 16.1, 16.2)), transports the degeneracy index, the boundary and tameness (Lemma 16.1.13, Definitions 16.1.14, 16.1.17, Lemma 16.1.19, Definition 16.1.20 (2017: Lemma 16.1, Definitions 16.9, 16.11, Lemma 16.2, Definition 16.12)), and introduces the raised polyfolds $(Z,c)^i$. It also treats the lifts Z_i, subpolyfolds and faces (Proposition 16.1.12, Definition 16.1.15, Remark 16.1.16, Example 16.1.18, Definition 16.1.21, Proposition 16.1.22), which are not formalized. §16.2 builds the tangent $T(Z,c)$, the tangent functor and the complex of sc-differential forms. §16.3 defines strong polyfold bundles, their maps, auxiliary norms, reflexivity, mixed convergence and sections. §16.4 defines branched finite-dimensional suborbifolds of a polyfold, their orientations and integrals, and proves Stokes' theorem. §16.5 defines sc$^+$-multisections of strong polyfold bundles and proves the extension theorem 16.5.7. §16.6 defines sc-Fredholm sections, their compactness properties and orientations, and states the integration theorem 16.6.6.

This Part follows the book's order. §§XVI.1–XVI.6 treat §16.1: polyfold structures and polyfolds with the metrizability remark (§XVI.1), the uniqueness statement after Definition 16.1.2 and Remark 16.1.7 (§XVI.2), Proposition 16.1.4 and Definition 16.1.5 (§XVI.3), the maps of polyfolds (§XVI.4), the degeneracy index, boundary and tameness (§XVI.5) and the raised polyfolds (§XVI.6). §§XVI.7–XVI.10 treat §16.2: Lemma 16.2.1 (§XVI.7), the tangent $T(Z,c)$ and the projection τ_Z (§XVI.8), Theorem 16.2.4 (§XVI.9) and sc-differential forms with Theorem 16.2.6 (§XVI.10). §§XVI.11–XVI.16 treat §16.3: strong polyfold bundles (§XVI.11), their maps (§XVI.12), auxiliary norms (§XVI.13), reflexivity and mixed convergence (§XVI.14), Theorems 16.3.15, 16.3.17 and Proposition 16.3.16 (§XVI.15), and sections with the zero section (§XVI.16). §§XVI.17–XVI.20 treat §16.4: branched suborbifolds (§XVI.17), Proposition 16.4.3 (§XVI.18), orientations and integrals (§XVI.19) and Stokes' theorem (§XVI.20). §§XVI.21–XVI.23 treat §16.5: sc$^+$-

multisections and (16.8) (§XVI.21), structurability (§XVI.22) and Theorem 16.5.7 (§XVI.23). §§XVI.24–XVI.26 treat §16.6: sc-Fredholm sections and Theorem 16.6.4 (§XVI.24), orientations (§XVI.25) and Theorem 16.6.6 (§XVI.26). Then come the witnesses (§XVI.27), what is not formalized (§XVI.28) and what the formalization taught us (§XVI.29).

What is proved, and what is not. All six sections of Chapter 16 are formalized, except Proposition 16.1.12, the subpolyfolds and faces of §16.1 and Remark 16.2.7.

Formalized as printed. Definitions 16.1.1, 16.1.2, 16.1.3, 16.1.5, 16.1.6, 16.1.8, 16.1.14, 16.1.17 and 16.1.20, Remark 16.1.9 and Lemma 16.1.13 (§§XVI.1, XVI.3–XVI.5). The remark after Definition 16.1.1 that Z is metrizable (§XVI.1). The construction of $T(Z,c)$ with the maps $T\alpha$ and (16.5), Lemma 16.2.2 and Definition 16.2.3 (§XVI.8). Definition 16.2.5 with the remark before it, and Theorem 16.2.6 in both parts, the complex and the pull-back by sc-smooth maps (§XVI.10). In §16.3: Definitions 16.3.1, 16.3.3, 16.3.4, 16.3.6, 16.3.7, 16.3.8, 16.3.12, 16.3.13, 16.3.14 and 16.3.18, Lemma 16.3.2, Proposition 16.3.10, Theorem 16.3.15, Proposition 16.3.16 (2), Theorem 16.3.17 (1), the parenthetical of Definition 16.3.12 that the model does not matter, the independence of the model of mixed convergence and of reflexive auxiliary norms, and the zero section (§§XVI.11–XVI.16). In §16.4: Definitions 16.4.1, 16.4.2, 16.4.4 and 16.4.5, Proposition 16.4.3 and the integrals of p. 732 on classes (§§XVI.17–XVI.19). In §16.5: Definitions 16.5.1, 16.5.4 and 16.5.6, Remark 16.5.3 and (16.8) with the continuity of $n(\lambda)$ (§§XVI.21–XVI.22). In §16.6: the claim before Definition 16.6.1, Definitions 16.6.1, 16.6.2 and 16.6.3, and Theorem 16.6.4 (§XVI.24). Where the text asserts that a relation is an equivalence relation, or lists a condition that the others imply, the relation is proved and the condition derived.

Restated. The raised polyfolds $(Z,c)^i$ and the projection τ_Z, with $(Z,c)^1$ a space injecting into Z with image Z_1 (§§XVI.6, XVI.8). Definitions 16.2.5, 16.4.1 and 16.4.4, whose representatives are made explicit as pairs (§§XVI.10, XVI.17, XVI.19). Definition 16.3.5 (2), (3) through representatives, Definition 16.1.21 not being formalized (§XVI.11). Definition 16.3.9 with n a function on Y whose values on $Y_{0,1}$ matter (§XVI.13). Definition 16.3.19 as the sc-smooth sections with an sc$^+$ functor (§XVI.16). Definition 16.5.2 with $y \neq 0_z$, since the set as printed is all of Z; Definition 16.5.5 with the pull-back over ∂X in orbit form (§§XVI.21–XVI.22).

Stronger. Proposition 16.1.4 with the text's sketch of part (2) written out (§XVI.3); Lemma 16.1.19 as an equivalence (§XVI.5); Proposition 16.3.16 (1) for every auxiliary norm, without reflexivity (§XVI.15). The metrizability of Z is proved without the Nagata–Smirnov theorem (§XVI.1).

Narrower. Definition 16.1.11: the polyfold category is built on effective polyfolds, since as we read Definition 16.1.10 the composite is not defined on all of them (§XVI.4). Theorem 16.2.4: a functor on the category of polyfold structures, well defined on sc-smooth maps of all polyfolds, and a functor on the category of effective polyfolds, the tangent of an effective polyfold being effective (§XVI.9). Theorem 16.3.17 (2), with the reflexive local step of Theorem 12.2.13 as a hypothesis, which Part XII discharges for tame bases (§XVI.15). Definition 16.6.5: an orientation on one representative, carried to every other along any diagram under the standing hypotheses of the M-polyfold theory on the bundles of the diagram (§XVI.25). Theorem 16.6.6: the integrals live on the polyfold and depend only on $[\tau]$; their independence of λ is proved from cobordisms between perturbations with the inherited orientation, both taken as inputs (§XVI.26). Proposition 16.4.3 and the integrals on classes are proved as printed; only the boundary integrals on classes are not wrapped (§XVI.19).

With an added hypothesis. Theorem 16.4.6, Stokes' theorem, with sc-smooth partitions of unity, which the Chapter 9 Stokes theorem it reduces to assumes (§XVI.20); Theorem 16.6.6 likewise (§XVI.26). Theorem

16.5.7, with tame strong bundle charts in the models and λ with non-empty index sets, which is the text's notion (§XVI.23).

Does not hold as we read it. Five statements, all by one mechanism: Theorem 10.3.19 (Part X) does not hold as we read it, on the ep-groupoid $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ with the trivial action, which satisfies (ZHOU) and has a paracompact orbit space, so it is a polyfold structure in the exact sense of Definition 16.1.1. (1) The sentence after Definition 16.1.2, that the generalized isomorphism f with $\alpha = \beta \circ |f|$ is unique as a consequence of (ZHOU) (§XVI.2). (2) Remark 16.1.7, that for a homeomorphism h there is at most one generalized isomorphism f with $h \circ \alpha = \beta \circ |f|$, together with the sentence on pp. 709–710 that an isomorphism $(f, \mathfrak{f})$ of polyfold structures is determined by f (§XVI.2). (3) Lemma 16.2.1 (§XVI.7), which holds on orbit spaces, the form §16.2 uses. (4) The claim of Definition 16.1.10 that the composite does not depend on the choices, on the middle structure $(\mathbb{Z}/3)^2 \times \mathbb{R} \rightrightarrows \mathbb{R}$ with the trivial action (§XVI.4). (5) The uniqueness of f and F after Definition 16.3.3, on the strong bundle $\mathbb{R} \times \mathbb{R}^k \to \mathbb{R}$ over $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ (§XVI.11). All five hold when the target, or the middle structure, is effective, and each such form is proved. The class-level notions of §§16.3–16.6 do not depend on the non-unique isomorphisms: a section is determined by its map f, a multisection by its function λ, a branched suborbifold by its function θ (§§XVI.16, XVI.21, XVI.26).

Not formalized. The second sentence of Remark 16.1.7, on continuous maps, which has no formal content beyond an example; Remark 16.3.11, which is prose. *Not yet formalized:* Proposition 16.1.12, Definition 16.1.15, Remark 16.1.16, Example 16.1.18, Definition 16.1.21, Proposition 16.1.22 and Remark 16.2.7; the boundary integrals of p. 732 as functions on classes; weak face structure under generalized isomorphisms.

Remaining gaps (§XVI.28). G.153: Stokes' theorem on polyfolds without partitions of unity. G.175, in part: the orientation of $\lambda \circ f$ inherited from (f, o) on the polyfold, and the cobordism of Corollary 15.4.4 on the polyfold. G.176, in part: the independence of the transported orientation of the diagram, and the transfer of tameness, bump functions and tame germ data along strong bundle equivalences. G.187: general position of (f, λ) does not depend on the model. G.188: Theorem 16.6.6 in index 0.

The decisions that shape the chapter.

(1) *Polyfolds as quotients.* A polyfold structure is a Lean structure holding the ep-groupoid, its two properties (paracompact orbit space, (ZHOU)) and the homeomorphism; a polyfold on Z is an element of the quotient of the polyfold structures on Z by the equivalence of Definition 16.1.2. Every notion of a polyfold is "some structure in c has the property", and it comes with the theorem that then every structure in c has it. The same pattern gives strong polyfold bundles (quotients of strong polyfold bundle structures), sc-smooth maps (quotients of morphisms of PS), forms, sections, branched suborbifolds and multisections (quotients of representatives).

(2) *Bump functions on the objects.* "Admits sc-smooth bump functions" in Proposition 16.1.4 (1) and Definition 16.1.5 (1) is read for the object M-polyfold of the ep-groupoid, pointwise (Definition 5.3.1), as the text's proof uses it; by Theorem 12.3.2 (1) (Part XII) this is equivalent to Definition 12.3.1 in the pointwise reading. Partitions of unity are read in the ep-groupoid sense of Definition 7.5.5, and shown equivalent to partitions of unity of the orbit space whose pull-backs to the objects are sc-smooth.

(3) *A base structure instead of a gluing.* The text builds $T(Z, c)$, and the raised polyfold $(Z, c)^1$, by gluing over all structures of c along canonical maps. The formalization chooses one structure (X_0, α_0) of c (the representative chosen by the quotient) and takes $T(Z, c) = |TX_0|$, $(Z, c)^1 = |X_0^1|$; every

other structure is attached to it by the maps $T\alpha$, α^1, which are proved independent of every choice. This avoids the gluing and makes visible that what the gluing needs is a canonical map on orbit spaces, not a canonical generalized isomorphism.

(4) *Effective polyfolds for composition.* As we read it, Definition 16.1.10 does not give a well-defined composite on all polyfolds (§XVI.4). The formalization keeps the category PS of polyfold structures for all structures, keeps sc-smooth maps of all polyfolds and everything that is defined map by map (the tangent of a map, the pull-back of forms), and builds the category of polyfolds on the effective ones, where Theorem 10.3.19 holds and the composite is well defined.

(5) *Functions determine the class-level objects.* In §§16.3, 16.5 and 16.6 the relation between representatives is stated with a generalized strong bundle isomorphism, which need not be unique. The formalization proves in each case that the relation holds iff the functions on Y or Z agree (the section f, the multisection λ, the function $\theta = |\Theta| \circ \alpha^{-1}$), so the non-uniqueness of the isomorphisms does not reach these notions.

(6) *Added hypotheses are named and witnessed.* Where the text's proof reduces to a statement of an earlier chapter that carries a hypothesis the polyfold statement does not print (partitions of unity in Stokes' theorem; tame strong bundle charts in Theorem 14.1.9; the reflexive local step of Theorem 12.2.13), the hypothesis is added to the polyfold statement, named, and witnessed (§XVI.27).

Map.

Polyfold structures and polyfolds (§16.1). - `Chapter16/PolyfoldStructure`: Definition 16.1.1, the equivalence of Definition 16.1.2, Definition 16.1.3, uniqueness for effective targets, Lemma 16.1.13, Definitions 16.1.14, 16.1.17, Lemma 16.1.19, Definition 16.1.20 (§§XVI.1, XVI.2, XVI.5). - `Chapter16/ZhouUniquenessCheck`: the polyfold structure on $\mathbb{R}$ given by $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$; the uniqueness after Definition 16.1.2 and Remark 16.1.7 as statements, with the example on which they do not hold as we read them (§§XVI.1–XVI.2). - `Chapter16/PolyfoldBump`: bump points along equivalences, Proposition 16.1.4 (1), Definition 16.1.5 (1) (§XVI.3). - `Chapter16/PolyfoldPartitions`: partitions of unity read on $|X|$, along equivalences, Proposition 16.1.4 (2), Definition 16.1.5 (2) (§XVI.3). - `Chapter16/PolyfoldExamples`: the witnesses on the polyfold $\mathbb{R}$ (§XVI.27). - `Chapter16/PolyfoldMaps`: the category PS, Definitions 16.1.6, 16.1.8, Remark 16.1.9, the composition for an effective middle structure, Definition 16.1.11 on effective polyfolds (§XVI.4). - `Chapter16/CompositionCounterexample`: the claim of Definition 16.1.10 and the example on which it does not hold as we read it (§XVI.4). - `Chapter16/RaisedPolyfold`: the raise of generalized maps, the raised polyfolds $(Z, c)^i$, and the tangent projection τ_Z (§§XVI.6, XVI.8).

The tangent and forms (§16.2). - `Chapter16/TangentLemma`: tangents of generalized maps, Lemma 16.2.1 as a statement, its example, its orbit form and its form for an effective target (§XVI.7). - `Chapter16/TangentPolyfold`: metrizability of polyfolds, $T(Z, c)$, (16.5), Lemma 16.2.2, Definition 16.2.3 (§§XVI.1, XVI.8). - `Chapter16/TangentFunctor`: the tangent functor on PS and on sc-smooth maps (§XVI.9). - `Chapter16/TangentEffective`: the tangent of an effective ep-groupoid with (ZHOU) is effective; the tangent functor on effective polyfolds (§XVI.9). - `Chapter16/FormsIndependence`, `Chapter16/PolyfoldForms`: the remark before Definition 16.2.5, Definition 16.2.5, Theorem 16.2.6, the complex (§XVI.10). - `Chapter16/FormsPullback`: Theorem 16.2.6, the pull-back by sc-smooth maps (§XVI.10).

Strong polyfold bundles (§16.3). - `Chapter16/StrongPolyfoldBundle`: Definitions 16.3.1, 16.3.3, 16.3.4, 16.3.5, Lemma 16.3.2, the induced polyfold (§XVI.11). - `Chapter16/PolyfoldBundleUniqueness`: the uniqueness after Definition 16.3.3, its example and its form for an effective target (§XVI.11). - `Chapter16/PolyfoldBundleCategory`: the category $\mathcal{SPBS}$, Definitions 16.3.6–16.3.8 (§XVI.12). - `Chapter16/`

`PolyfoldAuxNorm`: Definition 16.3.9 to Theorem 16.3.17 (§§XVI.13–XVI.15). - `Chapter16/ReflexivePull`: reflexive 1-fibres pull back along local strong bundle isomorphisms and equivalences (§XVI.14). - `Chapter16/ReflexivePush`: reflexive 1-fibres push forward along equivalences; the parenthetical of Definition 16.3.12 (§XVI.14). - `Chapter16/MixedTransfer`: mixed convergence and reflexive auxiliary norms along equivalences; Proposition 16.3.16 (2) (§§XVI.14–XVI.15). - `Chapter16/PolyfoldSections`: the relation before Definition 16.3.18, Definitions 16.3.18, 16.3.19 (§XVI.16). - `Chapter16/FibreZero`, `Chapter16/ZeroSection`: the zero of a fibre and the zero section (§XVI.16). - `Chapter16/PolyfoldBundleExamples`: the witnesses on the $\mathbb{Z}/3$ bundle (§XVI.27).

Branched suborbifolds (§16.4). - `Chapter16/BranchedSuborbifold`: Definitions 16.4.1, 16.4.2, 16.4.4, 16.4.5, Proposition 16.4.3 on one representative, the integrals on representatives, Theorem 16.4.6 (§§XVI.17–XVI.20). - `Chapter16/BranchedTame`: tameness along equivalences and generalized isomorphisms, Definition 16.4.2 (5), the integrals on classes (§§XVI.17, XVI.19). - `Chapter16/SuppNaturalityStatement`, `Chapter16/SuppNaturality`: the transition between the supports of two representatives, and Proposition 16.4.3 (§XVI.18).

Sc^+-multisections (§16.5). - `Chapter16/PolyfoldMultisections`: Definitions 16.5.1, 16.5.2, Remark 16.5.3, (16.8), Definitions 16.5.4–16.5.6, and the Lean form of Theorem 16.5.7 from the uncharged Theorem 14.1.9 (§§XVI.21–XVI.23). - `Chapter16/StructurablePullback`: Definition 16.5.4, "and therefore all" (§XVI.22). - `Chapter16/RepresentativeChecks`: the multisection relation on the $\mathbb{Z}/3$ example (§XVI.21). - `Chapter16/NormLamContinuous`: the continuity of $N(\Lambda)$ and of $n(\lambda)$ in (16.8) (§XVI.21). - `Chapter16/PolyfoldBoundaryExtension`: Theorem 16.5.7 from the charged Theorem 14.1.9 (§XVI.23).

Sc-Fredholm sections (§16.6). - `Chapter16/PolyfoldFredholmSections`: the claim before Definition 16.6.1, Definitions 16.6.1–16.6.3, Theorem 16.6.4, Definition 16.6.5 on a representative, the reduction and the choice of λ in Theorem 16.6.6 (§§XVI.24–XVI.26). - `Chapter16/OrientationTransport`: the transport of orientations in Definition 16.6.5 (§XVI.25). - `Chapter16/PerturbedSuborbifold`: $\lambda \circ f$ as a branched suborbifold (§XVI.26). - `Chapter16/PerturbedIntegralIndependence`: the integrals of Theorem 16.6.6 on the polyfold, cobordisms, Theorem 16.6.6 (§XVI.26).

Throughout, a generalized map $\mathfrak{f} = [X \xleftarrow{F} A \xrightarrow{\Phi} Y]$ is a morphism of Chapter 10's localization of the category $\mathcal{EP}$ of ep-groupoids at the equivalences; its orbit map is $|\mathfrak{f}| = |\Phi| \circ |F|^{-1} : |X| \to |Y|$, and it is a generalized isomorphism if it is invertible in the localization. (ZHOU) is Zhou's condition of Chapter 7, (LR) the local regularity property of Chapter 10, and an ep-groupoid is effective if the only isotropy element acting trivially near its object is the identity (Definition 7.2.1).

XVI.1 Definitions 16.1.1–16.1.3 (2017: 16.1–16.3): polyfold structures and polyfolds, pp. 705–707

Statement (same). *Definition 16.1.1* (p. 705) `Chapter16/PolyfoldStructure · PolyfoldStructure`: a polyfold structure on a topological space Z is a pair (X, β) of an ep-groupoid X and a homeomorphism $\beta : |X| \to Z$ such that (1) the orbit space $|X|$ is paracompact and (2) X satisfies (ZHOU). *Definition 16.1.2* (p. 707) `Chapter16/PolyfoldStructure · PolyfoldStructure.Equiv`: two polyfold structures (X, α), (Y, β) on Z are equivalent if there is a generalized isomorphism $f : X \to Y$ with $\alpha = \beta \circ |f|$. *Definition 16.1.3* (p. 707) `Chapter16/PolyfoldStructure · PolyfoldClass`: a polyfold is a pair (Z, c) with c an equivalence class of polyfold structures on Z. *The remark after Definition 16.1.1* (same) `Chapter16/TangentPolyfold · PolyfoldStructure.metrizableSpace`: if Z carries a polyfold structure, Z is metrizable.

Readings. Z lives in the universe of the object and morphism sets of X, so that β is a homeomorphism between types of one universe; a polyfold on Z is therefore a class of structures whose ep-groupoids live in that universe. The 2017 Definition 16.1 had neither (1) nor (2); both are part of the formal structure, and every theorem of this Part that needs (LR), (LUC), metrizability or the existence of auxiliary norms obtains it from them. The pair (X, β) is an orbit chart in the sense of Remark 10.3.18 `Chapter16/PolyfoldStructure · PolyfoldStructure.toOrbitChart`, and Definition 16.1.2 is the relation of Remark 10.3.18 on orbit charts `Chapter16/PolyfoldStructure · PolyfoldStructure.equiv_iff_rel`.

Proof that Definition 16.1.2 is an equivalence relation. The text calls the relation an equivalence relation without proof; it is proved in three steps.

Step 1, reflexivity `Chapter16/PolyfoldStructure · PolyfoldStructure.Equiv.refl`. The identity 1_X of the localization is a generalized isomorphism and $|1_X| = \mathrm{id}_{|X|}$, so $\alpha = \alpha \circ |1_X|$.

Step 2, symmetry `Chapter16/PolyfoldStructure · PolyfoldStructure.Equiv.symm`. If $f : X \to Y$ is a generalized isomorphism with $\alpha = \beta \circ |f|$, its inverse f^{-1} in the localization is a generalized isomorphism with $|f^{-1}| = |f|^{-1}$ (Proposition 10.3.11, Part X). Then $\beta = \alpha \circ |f|^{-1} = \alpha \circ |f^{-1}|$.

Step 3, transitivity `Chapter16/PolyfoldStructure · PolyfoldStructure.Equiv.trans`. For $f : X \to Y$ and $g : Y \to V$ with $\alpha = \beta \circ |f|$ and $\beta = \gamma \circ |g|$, the composite $g \circ f$ is a generalized isomorphism with $|g \circ f| = |g| \circ |f|$ (Proposition 10.3.11), so $\alpha = \gamma \circ |g \circ f|$.

The quotient by this relation `Chapter16/PolyfoldStructure · PolyfoldStructure.setoid` is the type of polyfolds on Z. A consequence used throughout: if $(X, \alpha) \sim (Y, \beta)$ through f, then $|f| = \beta^{-1} \circ \alpha$ `Chapter16/PolyfoldStructure · PolyfoldStructure.orbitMap_eq_of_equiv`, since β is a bijection. So the orbit map of a realizing generalized isomorphism is determined by the two structures, even though (§XVI.2) the generalized isomorphism itself is not.

(ZHOU) gives (LR) `Chapter16/PolyfoldStructure · PolyfoldStructure.isLR`. *Proof.* Proposition 7.4.22 (Part VII) `Chapter7/SmoothRegularAssembly · proposition_7_4_22_of_isZhou` shows that an ep-groupoid with (ZHOU) has the local regularity property. This is the hypothesis the text has in mind when it cites Theorem 10.3.19 after Definition 16.1.2, and the hypothesis of Proposition 10.1.10 and Proposition 11.2.9, which carry §16.2 (§§XVI.7–XVI.10).

Proof of the remark: polyfolds are metrizable. *Step 1.* $|X|$ is paracompact by Definition 16.1.1 (1). *Step 2.* Theorem 7.3.1 (Part VII) gives that $|X|$ is Hausdorff, regular and locally metrizable; with paracompactness, $|X|$ is metrizable `Chapter7/OrbitTopology · theorem_7_3_1_metrizable`. *Step 3, the metrization step.* It is the theorem of Chapter 2 (Part II) that a paracompact Hausdorff space which is locally metrizable is metrizable `Chapter2/Metrizable · metrizableSpace_of_locally`, proved through the pull-back of a metrizable topology along an embedding `Chapter2/Metrizable · metrizableSpace_of_pullback`. The Nagata–Smirnov theorem, which the text's appeal to metrization theorems suggests, is not needed. *Step 4.* β is a homeomorphism, so the metrizable topology of $|X|$ carries over to Z. The text's 2017 Proposition 16.1 is this remark.

The polyfold $\mathbb{R}$ with isotropy $\mathbb{Z}/3$. This example is the witness of every definition of §16.1 and the counterexample of §XVI.2, so it is built with care. Let $X = \mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ be the action groupoid of the trivial action of $\mathbb{Z}/3$ on $\mathbb{R}$: objects $\mathbb{R}$, morphisms $\mathbb{Z}/3 \times \mathbb{R}$, source and target the projection.

Step 1, the orbit space. The orbit map $\pi : \mathbb{R} \to |X|$ is injective, since every orbit is a point `Chapter16/ZhouUniquenessCheck · EpGroupoid.Examples.injective_π_trivialZ3`. It is continuous and open (Proposition 7.1.8, Part VII), and surjective, hence a homeomorphism `Chapter16/ZhouUniquenessCheck · EpGroupoid.Examples.`

isHomeomorph_π_trivialZ3. Its inverse gives $|X| \cong \mathbb{R}$ Chapter16/ZhouUniquenessCheck · EpGroupoid.Examples.trivialZ3OrbitHomeomorph.

Step 2, paracompactness. $\mathbb{R}$ is paracompact, hence so is $|X|$ Chapter16/ZhouUniquenessCheck · EpGroupoid.Examples.hasParacompactOrbitSpace_trivialZ3.

Step 3, (ZHOU). Every isotropy element acts trivially, so for every x the natural representation of G_x is trivial and the conditions of (ZHOU) hold with the whole of $\mathbb{R}$ as the neighbourhood Chapter7/Zhou · EpGroupoid.Examples.isZhou_trivialZ3.

Step 4, the structure. With β the inverse of the homeomorphism of Step 1, (X, β) is a polyfold structure on $\mathbb{R}$ in the exact sense of Definition 16.1.1 Chapter16/ZhouUniquenessCheck · PolyfoldStructure.z3PolyfoldStructure, and its class is a polyfold Chapter16/ZhouUniquenessCheck · PolyfoldStructure.z3Polyfold.

Step 5, not effective. The non-trivial elements of $\mathbb{Z}/3$ act as the identity near every object, so X is not effective Chapter16/ZhouUniquenessCheck · PolyfoldStructure.not_isEffective_z3PolyfoldStructure. This is what makes the example a counterexample to the uniqueness statements, and why their effective forms hold.

Where Lean departs from the text. The text states Definitions 16.1.1–16.1.3 and treats the relation of Definition 16.1.2 as evidently an equivalence relation; the formalization proves the three properties from Proposition 10.3.11, the only input being that orbit maps of generalized maps compose and invert. The universe in which Z lives is implicit in the text; the formalization fixes it to be that of the object and morphism sets of X, which costs nothing because every construction of the chapter stays inside one universe or moves up by one (the tangent). The metrizability remark is proved by a different route from the one the 2017 text suggests: instead of a general metrization theorem for the orbit space, Theorem 7.3.1 provides local metrizability, and the Chapter 2 theorem for paracompact Hausdorff spaces finishes. The polyfold $\mathbb{R}$ with isotropy $\mathbb{Z}/3$ is not in the text; it is the example of Part X carried to polyfolds, and it serves both as the universal witness of the definitions and as the example of §XVI.2.

XVI.2 The uniqueness after Definition 16.1.2, Remark 16.1.7 (2017: Remark 16.1), and the sentence on pp. 709–710

Statement (does not hold as we read it; holds for an effective target). After Definition 16.1.2 (p. 707) the text says that the generalized isomorphism f with $\alpha = \beta \circ |f|$ is necessarily unique as a consequence of (ZHOU), citing Theorem 10.3.19: for generalized isomorphisms $f, f' : X \to Y$, $|f| = |f'|$ implies $f = f'$ if one of the ep-groupoids has (LR). The claim in Lean Chapter16/ZhouUniquenessCheck · PolyfoldStructure.Uniqueness_16_1_2: for polyfold structures (X, α), (Y, β) on Z, at most one generalized isomorphism f has $\alpha = \beta \circ |f|$. Remark 16.1.7 (p. 711) Chapter16/ZhouUniquenessCheck · PolyfoldStructure.Remark_16_1_7: for a homeomorphism $h : Z \to W$, a polyfold structure (X, α) on Z and one (Y, β) on W, at most one generalized isomorphism f has $h \circ \alpha = \beta \circ |f|$. The sentence on pp. 709–710: an isomorphism $(f, \mathfrak{f})$ of polyfold structures in the category PS is determined by f.

Verdict. The uniqueness after Definition 16.1.2 does not hold as we read it Chapter16/ZhouUniquenessCheck · PolyfoldStructure.not_uniqueness_16_1_2, nor does Remark 16.1.7 Chapter16/ZhouUniquenessCheck · PolyfoldStructure.not_remark_16_1_7, nor the sentence on pp. 709–710. All three hold when the target ep-groupoid is effective Chapter16/PolyfoldStructure · PolyfoldStructure.uniqueness_16_1_2_of_isEffective Chapter16/PolyfoldStructure · PolyfoldStructure.remark_16_1_7_of_isEffective Chapter16/ZhouUniquenessCheck · PolyfoldStructure.uniqueness_16_1_2_of_forall_isEffective.

Proof that the uniqueness does not hold as we read it. *Step 1, the structure.* Take the polyfold structure (X, β) on $\mathbb{R}$ of §XVI.1, with $X = \mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ and the trivial action, as both (X, α) and (Y, β). All hypotheses of Definition 16.1.1 hold: paracompact orbit space, (ZHOU), and a homeomorphism to $\mathbb{R}$ `Chapter16/ZhouUniquenessCheck · PolyfoldStructure.uniqueness_16_1_2_counterexample`.

Step 2, two generalized isomorphisms. Let $\mathrm{Inv} : X \to X$ be the functor that is the identity on objects and inverts morphisms; since $\mathbb{Z}/3$ is abelian and acts trivially, Inv is a functor, and it is an equivalence. Take $f = [1_X]$ `Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.genId` and $f' = [X \xleftarrow{1} X \xrightarrow{\mathrm{Inv}} X]$ `Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.genInv`. Both are generalized isomorphisms `Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.isGeneralizedIso_genInv`.

Step 3, both realize the equivalence. Both functors are the identity on objects, so both orbit maps are the identity of $|X|$, and $\beta = \beta \circ |f|$ `Chapter16/ZhouUniquenessCheck · PolyfoldStructure.β_eq_β_comp_orbitMap_genId` and $\beta = \beta \circ |f'|$ `Chapter16/ZhouUniquenessCheck · PolyfoldStructure.β_eq_β_comp_orbitMap_genInv`.

Step 4, they differ `Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.genInv_ne_genId`. Two morphisms of the localization represented by functors $X \to X$ through the identity leg agree only if the functors are connected by a natural transformation after a refinement. A natural transformation from 1 to Inv would be a family $\tau_x \in \mathbb{Z}/3$ with $\tau_x g = g^{-1}\tau_x$, that is $g = g^{-1}$, for every g; this fails for a generator. The argument is the one of Part X, where it shows that Theorem 10.3.19 does not hold as we read it `Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.not_theorem_10_3_19`.

Step 5, conclusion. (ZHOU) gives (LR) (§XVI.1), so the text's citation of Theorem 10.3.19 applies to this X, and the example shows that (LR) does not give the uniqueness. For Remark 16.1.7, take $h = \mathrm{id}_{\mathbb{R}}$ in the same example. For the sentence on pp. 709–710, the pairs (id, f) and (id, f') are two isomorphisms of PS with the same continuous map.

Proof of the effective form. *Step 1.* If Y is effective, Theorem 10.3.19 holds `Chapter10/LocalizationLRCounterexample · EPLocalization.EPLoc.theorem_10_3_19_of_isEffective` (Part X): an effective target rules out isotropy acting trivially, which is what Step 4 above uses. *Step 2.* Two generalized isomorphisms f, f' with $\beta \circ |f| = h \circ \alpha = \beta \circ |f'|$ have $|f| = |f'|$, because β is injective. *Step 3.* By Step 1, $f = f'$. The form for $h = \mathrm{id}$ is the uniqueness after Definition 16.1.2; the form quantified over all effective polyfold structures is a corollary.

What depends on the uniqueness. Definitions 16.1.2 and 16.1.3 do not: an equivalence of structures asks only that some generalized isomorphism exist. Nor do Definition 16.1.6, which carries its generalized isomorphisms as data, the invariance statements of §16.1, or any of the class-level definitions of §§16.3–16.6 (decision (5)). The uniqueness is used in the text in three places: Lemma 16.2.1 and the gluing of $T(Z, c)$ (§§XVI.7–XVI.8), where the orbit form suffices; the claim of Definition 16.1.10 (§XVI.4), which does not hold as we read it; and the uniqueness after Definition 16.3.3 (§XVI.11), which does not hold as we read it either. The second sentence of Remark 16.1.7, that for a continuous map there may be none or many generalized maps, is an observation without formal content beyond an example and is not formalized.

Where Lean departs from the text. The text's argument is one sentence: (ZHOU), then Theorem 10.3.19. The formalization splits it into its two steps and tests each. The first, (ZHOU) gives (LR), is Proposition 7.4.22 and holds. The second, (LR) gives the uniqueness, is Theorem 10.3.19 and does not hold as we read it; the example of Part X satisfies every hypothesis of Definition 16.1.1, so the polyfold statement inherits the gap exactly. The effective form keeps the text's two steps and replaces Theorem 10.3.19 by

its effective form. The formalization does not attempt to strengthen (ZHOU) or (LR) to a condition that would restore uniqueness without effectiveness; effectiveness is the condition under which Part X proves Theorem 10.3.19, and it is the one the rest of this Part uses.

XVI.3 Proposition 16.1.4 (2017: Proposition 16.2) and Definition 16.1.5 (2017: Definition 16.4), p. 708

Statement. *Proposition 16.1.4 (1)* (same) `Chapter16/PolyfoldBump · PolyfoldStructure.proposition_16_1_4_one`: for equivalent polyfold structures $(X, \alpha) \sim (Y, \beta)$, the object M-polyfold of X admits sc-smooth bump functions iff that of Y does. *Proposition 16.1.4 (2)* (explicit) `Chapter16/PolyfoldPartitions · PolyfoldStructure.proposition_16_1_4_two`: X admits sc-smooth partitions of unity in the sense of Definition 7.5.5 iff Y does. Both together `Chapter16/PolyfoldPartitions · PolyfoldStructure.proposition_16_1_4`. *Definition 16.1.5* (same) `Chapter16/PolyfoldBump · PolyfoldClass.AdmitsBumpFunctions` `Chapter16/PolyfoldPartitions · PolyfoldClass.AdmitsScPartitionsOfUnity`: a polyfold admits sc-smooth bump functions, or sc-smooth partitions of unity, if some structure in c does; then every structure does `Chapter16/PolyfoldBump · PolyfoldClass.definition_16_1_5_one` `Chapter16/PolyfoldPartitions · PolyfoldClass.definition_16_1_5_two`. *Verdict* for (2): "explicit", because the text's proof of (2) is a sketch, calling a step an easy exercise; the steps below fill it.

Proof of (1). *Step 0, reduction to one equivalence.* An equivalence of structures is realized by a diagram $X \xleftarrow{F} A \xrightarrow{G} Y$ of equivalences of ep-groupoids, so it suffices to show that bump functions pass in both directions along one equivalence $F : A \to X$ `Chapter16/PolyfoldBump · EpFunctor.IsEquivalence.admitsBumpFunctions_iff`.

Step 1, bump functions are local. Call a point a bump point if there are sc-smooth bump functions at it, in every neighbourhood. An M-polyfold admits bump functions iff every point is a bump point. Sc-smoothness of a real function is local `Chapter16/PolyfoldBump · MPolyfold.isScSmoothMap_real_of_locally`, so a function that is sc-smooth near its support and 0 elsewhere is sc-smooth.

Step 2, bump points along sc-diffeomorphisms of open sets `Chapter16/PolyfoldBump · MPolyfold.IsScDiffeoOn.hasBumpAt`. Let $\varphi : U \to U'$ be an sc-diffeomorphism of open sets with $\varphi(a) = b$, and b a bump point. For a neighbourhood V of a, choose a bump function g at b supported in a small neighbourhood inside $\varphi(V \cap U)$ whose closure is inside U'; then $g \circ \varphi$ on U, extended by 0, is sc-smooth by Step 1 and is a bump function at a supported in V.

Step 3, along an equivalence `Chapter16/PolyfoldBump · EpFunctor.IsEquivalence.hasBumpAt_of_hasBumpAt_obj` `Chapter16/PolyfoldBump · EpFunctor.IsEquivalence.hasBumpAt_obj_of_hasBumpAt`. An equivalence is a local sc-diffeomorphism on objects (Chapter 10), so Step 2 carries bump points from $F(a)$ to a and from a to $F(a)$.

Step 4, essential surjectivity `Chapter16/PolyfoldBump · EpGroupoid.hasBumpAt_tgt`. Every $y \in X$ is the target of a morphism $\psi : F(a) \to y$. The local sc-diffeomorphism $\hat{\psi} = t \circ (s|_{U(\psi)})^{-1}$ of the morphism, defined near $F(a)$, sends $F(a)$ to y, so by Step 2 bump points are invariant under $\hat{\psi}$, and y is a bump point if $F(a)$ is. With Step 3 every object of X is a bump point if every object of A is; the converse is Step 3 alone.

Proof of (2). *Step 1, read on the orbit space.* Definition 7.5.5 holds for X iff every open cover of $|X|$ has a subordinate partition of unity (σ_λ) of $|X|$ with every $\sigma_\lambda \circ \pi$ sc-smooth `Chapter16/PolyfoldPartitions · EpGroupoid.HasOrbitScPartitionsOfUnity` `Chapter16/PolyfoldPartitions · EpGroupoid.hasScPartitionsOfUnity_iff_orbit`. The proof has three ingredients. An invariant continuous function on the objects descends to a continuous

function on $|X|$ `Chapter16/PolyfoldPartitions · EpGroupoid.descendP3Z`, so an ep-groupoid partition of unity, which is invariant, gives one of $|X|$. Closures commute with π^{-1}, because π is open `Chapter16/PolyfoldPartitions · EpGroupoid.preimage_closure_π`, so subordination to a saturated cover upstairs is subordination to the image cover downstairs. And a partition of unity of $|X|$ pulls back along the continuous map π to a family that is again locally finite with sum 1 `Chapter16/PolyfoldPartitions · PartitionOfUnity.comapP3Z`.

Step 2, the text's "easy exercise" `Chapter16/PolyfoldPartitions · EpFunctor.IsEquivalence.isScSmoothMap_comp_π_of_comp_obj`. For an equivalence $F : A \to X$ and $g : |X| \to \mathbb{R}$: if $g \circ \pi_X \circ F$ is sc-smooth on the objects of A, then $g \circ \pi_X$ is sc-smooth on the objects of X. Near a point $F(a)$, $g \circ \pi_X = (g \circ \pi_X \circ F) \circ F_{\mathrm{loc}}^{-1}$ with F_{loc}^{-1} a local inverse of F, which exists because F is a local sc-diffeomorphism. Near a point y isomorphic to $F(a)$ through ψ, $g \circ \pi_X = (g \circ \pi_X) \circ \widehat{\psi}^{-1}$ near y, because π_X is invariant under $\widehat{\psi}$; so sc-smoothness near $F(a)$ gives it near y. The converse direction, that $g \circ \pi_X$ sc-smooth gives $g \circ \pi_X \circ F$ sc-smooth, is the chain rule.

Step 3, transport. $|F| : |A| \to |X|$ is a homeomorphism (Chapter 10, Part X), so partitions of unity of $|X|$ and of $|A|$ correspond under composition with $|F|$, and $\sigma \circ \pi_X \circ F = \sigma \circ |F| \circ \pi_A$. With Step 2 the property of Step 1 passes from A to X and back `Chapter16/PolyfoldPartitions · EpFunctor.IsEquivalence.hasScPartitionsOfUnity_iff`, and along a diagram by two applications.

Proof of Definition 16.1.5. By Proposition 16.1.4 applied to any two structures of c. *Where Lean departs from the text.* The text's proof of (1) goes through local inverses and $\widehat{\psi}$ as here. Its proof of (2) indicates the reduction to the orbit space; Steps 1–3 are the details. The reading of bump functions on the object M-polyfold is decision (2).

Why the reading on the objects. Proposition 16.1.4 (1) could be read for the ep-groupoid in the sense of Definition 12.3.1, with bump functions that are themselves invariant. The text's proof works with bump functions on the object M-polyfold and moves them by local inverses and by $\widehat{\psi}$, which does not preserve invariance; so the reading on the objects is the one the proof supports. By Theorem 12.3.2 (1) the two readings agree pointwise, so nothing is lost. For partitions of unity the opposite holds: the text's Definition 7.5.5 is the ep-groupoid notion, and the formalization keeps it, proving the orbit-space form as a lemma rather than replacing the definition.

XVI.4 Definitions 16.1.6–16.1.11 (2017: Definitions 16.5–16.8) and Remark 16.1.9 (2017: Remark 16.2): maps of polyfolds, pp. 709–711

Statement. *The category PS* (p. 709, same) `Chapter16/PolyfoldMaps · PSCat`: objects are polyfold structures; a morphism $(X, \alpha) \to (Y, \beta)$ is a pair $(f, \mathfrak{f})$ of a continuous map $f : Z \to W$ and a generalized map $\mathfrak{f} : X \to Y$ with $f \circ \alpha = \beta \circ |\mathfrak{f}|$ `Chapter16/PolyfoldMaps · PSHom`. *Definition 16.1.6* (p. 710, same) `Chapter16/PolyfoldMaps · PSHom.Equiv`: $(f, \mathfrak{f}) \sim (f', \mathfrak{f}')$ if $(f', \mathfrak{f}') \circ (h, \mathrm{Id}_Z) = (k, \mathrm{Id}_W) \circ (f, \mathfrak{f})$ for isomorphisms (h, Id_Z), (k, Id_W) of PS. *Definition 16.1.8 and Remark 16.1.9* (p. 711, same) `Chapter16/PolyfoldMaps · PolyfoldClass.ScMap` `Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.remark_16_1_9`: an sc-smooth map $(Z, c) \to (W, d)$ is an equivalence class $[(f, \mathfrak{f})]$ of morphisms between structures of c and d, and its underlying continuous map is f. *Definition 16.1.10* (p. 711, does not hold as we read it; holds for an effective middle structure) `Chapter16/PolyfoldMaps · PSHom.Definition_16_1_10` `Chapter16/CompositionCounterexample · CompositionCounterexample.not_definition_16_1_10` `Chapter16/PolyfoldMaps · PSHom.Equiv.comp_of_isEffective`: $\widehat{g} \circ \widehat{f} = [(g \circ f, \mathfrak{g} \circ \mathfrak{f})]$ for representatives with a common middle structure, and

the text states that this does not depend on the choices. *Definition 16.1.11* (p. 711, narrower) `Chapter16/PolyfoldMaps · EffPolyfold`: the category of effective polyfolds and sc-smooth maps.

Proof that PS is a category. *Step 1, the continuous map is determined* `Chapter16/PolyfoldMaps · PSHom.f_eq` `Chapter16/PolyfoldMaps · PSHom.continuous_f`: from $f\circ\alpha = \beta\circ|\mathfrak{f}|$, $f = \beta\circ|\mathfrak{f}|\circ\alpha^{-1}$, a composite of continuous maps, since orbit maps of generalized maps are continuous (Part X). So the text's requirement that f be continuous is a consequence, and a morphism is determined by its generalized map `Chapter16/PolyfoldMaps · PSHom.ext`; every generalized map defines a morphism `Chapter16/PolyfoldMaps · PSHom.ofGen`.

Step 2, identities and composition `Chapter16/PolyfoldMaps · PSHom.id` `Chapter16/PolyfoldMaps · PSHom.comp`: $(\mathrm{id}_Z, 1_X)$, and $(g,\mathfrak{g})\circ(f,\mathfrak{f}) = (g\circ f, \mathfrak{g}\circ\mathfrak{f})$, which is a morphism because $|\mathfrak{g}\circ\mathfrak{f}| = |\mathfrak{g}|\circ|\mathfrak{f}|$ (Proposition 10.3.11). *Step 3, the laws* `Chapter16/PolyfoldMaps · PSHom.comp_assoc`: componentwise, from those of the localization.

Step 4, isomorphisms over the identity `Chapter16/PolyfoldMaps · PSHom.IsIdIso`: a morphism (h, Id_Z) between structures on one space Z with h a generalized isomorphism. They have inverses of the same kind `Chapter16/PolyfoldMaps · PSHom.IsIdIso.inv`, compose `Chapter16/PolyfoldMaps · PSHom.IsIdIso.comp` and include the identities `Chapter16/PolyfoldMaps · PSHom.isIdIso_id`; for one of them, $\alpha = \beta\circ|h|$ `Chapter16/PolyfoldMaps · PSHom.IsIdIso.β_eq`, so two structures are related by one iff they are equivalent in the sense of Definition 16.1.2, and one exists between any two equivalent structures `Chapter16/PolyfoldMaps · PSHom.exists_isIdIso`. For two structures of one class the formalization fixes one such isomorphism `Chapter16/PolyfoldMaps · PolyfoldClass.transport` `Chapter16/PolyfoldMaps · PolyfoldClass.transport_isIdIso`; it is used to define composites of representatives below.

Proof of Definition 16.1.6 and Definition 16.1.8. *Step 1, the continuous maps agree* `Chapter16/PolyfoldMaps · PSHom.Equiv.f_eq`: comparing the continuous components of the square, $f'\circ\mathrm{Id}_Z = \mathrm{Id}_W\circ f$. *Step 2, an equivalence relation* `Chapter16/PolyfoldMaps · PSHom.Equiv.refl` `Chapter16/PolyfoldMaps · PSHom.Equiv.symm` `Chapter16/PolyfoldMaps · PSHom.Equiv.trans`: reflexive with $h = 1$, $k = 1$; symmetric with the inverses h^{-1}, k^{-1}, multiplying the square by them; transitive by pasting two squares, with the composites $h'\circ h$, $k'\circ k$ of isomorphisms over the identity. The text states the relation without proof. *Step 3, the representatives* `Chapter16/PolyfoldMaps · PolyfoldClass.MapRep` `Chapter16/PolyfoldMaps · PolyfoldClass.MapRep.setoid`: morphisms of PS from a structure of c to a structure of d, with the relation; composing a representative with isomorphisms over the identity on either side stays in its class `Chapter16/PolyfoldMaps · PSHom.equiv_comp_left` `Chapter16/PolyfoldMaps · PSHom.equiv_comp_right`. *Step 4, Definition 16.1.8.* An sc-smooth map is a class `Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.mk`. Every class has a representative between any two given structures of c and d `Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.exists_rep`: compose a representative $(f,\mathfrak{f}) : (X',\alpha') \to (Y',\beta')$ with the chosen isomorphisms $(X,\alpha)\to(X',\alpha')$ and $(Y',\beta')\to(Y,\beta)$ and use Step 3. *Step 5, Remark 16.1.9* `Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.toFun`: the continuous map of the class is $\beta\circ|\mathfrak{f}|\circ\alpha^{-1}$ for every representative, by Step 1 and Step 1 of PS. *Step 6, identities* `Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.id` `Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.id_eq`: $1_{(Z,c)} = [(\mathrm{Id}_Z, [1_X])]$, the same class for every $(X,\alpha)\in c$, since two such representatives are related by the chosen isomorphism on both sides.

Proof that the claim of Definition 16.1.10 does not hold as we read it. *The claim in Lean:* if $(f,\mathfrak{f})\sim(f',\mathfrak{f}')$ and $(g,\mathfrak{g})\sim(g',\mathfrak{g}')$, and both pairs have a common middle structure, then the composites are equivalent. The example uses only the printed hypotheses: polyfold structures and morphisms of PS.

Step 1, the structures. $Z = W = V = \mathbb{R}$. $(X,\alpha) = (U,\gamma)$ is the polyfold structure $\mathbb{Z}/3\times\mathbb{R} \rightrightarrows \mathbb{R}$ with the trivial action (§XVI.1), with $\gamma\circ\pi = \mathrm{id}$ `Chapter16/CompositionCounterexample · CompositionCounterexample.z3_β_π`. (Y,β) is $(\mathbb{Z}/3)^2\times\mathbb{R}\rightrightarrows\mathbb{R}$, the action groupoid

of the trivial action of $K = (\mathbb{Z}/3)^2$ Chapter16/CompositionCounterexample · CompositionCounterexample.K2 Chapter16/CompositionCounterexample · CompositionCounterexample.k2EpGroupoid. As in §XVI.1, its orbit map is injective Chapter16/CompositionCounterexample · CompositionCounterexample.injective_π_k2 and a homeomorphism Chapter16/CompositionCounterexample · CompositionCounterexample.isHomeomorph_π_k2, $|Y| \cong \mathbb{R}$ Chapter16/CompositionCounterexample · CompositionCounterexample.k2OrbitHomeomorph, it satisfies (ZHOU) Chapter16/CompositionCounterexample · CompositionCounterexample.isZhou_k2, and (Y, β) is a polyfold structure Chapter16/CompositionCounterexample · CompositionCounterexample.k2Structure with $\beta \circ \pi = \mathrm{id}$ Chapter16/CompositionCounterexample · CompositionCounterexample.k2Structure_β_π. All continuous maps are the identity of $\mathbb{R}$.

Step 2, the functors. All are the identity on objects: $\iota : \mathbb{Z}/3 \to K$, $\iota(g) = (g, 1)$ Chapter16/CompositionCounterexample · CompositionCounterexample.ι; $\sigma : K \to K$, the swap of the two factors Chapter16/CompositionCounterexample · CompositionCounterexample.σ, with $\sigma \circ \sigma = 1$ Chapter16/CompositionCounterexample · CompositionCounterexample.σ_σ; $\mathrm{pr}_1 : K \to \mathbb{Z}/3$ Chapter16/CompositionCounterexample · CompositionCounterexample.pr₁; and $T : \mathbb{Z}/3 \to \mathbb{Z}/3$, $T(g) = 1$ Chapter16/CompositionCounterexample · CompositionCounterexample.T. The orbit map of the generalized map of a functor that is the identity on objects is the identity on orbits Chapter16/CompositionCounterexample · CompositionCounterexample.orbitMap_map_π, so every pair $(\mathrm{Id}, [\Phi])$ below is a morphism of PS.

Step 3, two equivalent representatives of $\hat{f}$. For $k \in \{1, \sigma\}$ let $a_k = (\mathrm{Id}, [\iota] \circ [k]) : (X, \alpha) \to (Y, \beta)$ Chapter16/CompositionCounterexample · CompositionCounterexample.a, and $b = (\mathrm{Id}, [\mathrm{pr}_1]) : (Y, \beta) \to (U, \gamma)$ Chapter16/CompositionCounterexample · CompositionCounterexample.b. $[\sigma]$ is a generalized isomorphism, its own inverse Chapter16/CompositionCounterexample · CompositionCounterexample.isGeneralizedIso_σ, so $(\mathrm{Id}, [\sigma])$ Chapter16/CompositionCounterexample · CompositionCounterexample.kσ is an isomorphism over the identity Chapter16/CompositionCounterexample · CompositionCounterexample.kσ_isIdIso. The square of Definition 16.1.6 with $h = 1$ and $k = [\sigma]$ commutes, so $a_1 \sim a_\sigma$ Chapter16/CompositionCounterexample · CompositionCounterexample.a_equiv.

Step 4, the composites. $b \circ a_1$ has generalized map $[\iota] \circ [\mathrm{pr}_1] = [\mathrm{pr}_1 \circ \iota] = [1_X]$ Chapter16/CompositionCounterexample · CompositionCounterexample.ι_pr₁ Chapter16/CompositionCounterexample · CompositionCounterexample.gen_comp_one, and $b \circ a_\sigma$ has $[\mathrm{pr}_1 \circ \sigma \circ \iota] = [T]$, since $\mathrm{pr}_1(\sigma(g, 1)) = \mathrm{pr}_1(1, g) = 1$ Chapter16/CompositionCounterexample · CompositionCounterexample.ι_σ_pr₁ Chapter16/CompositionCounterexample · CompositionCounterexample.gen_comp_σ.

Step 5, not equivalent Chapter16/CompositionCounterexample · CompositionCounterexample.not_equiv_comp. Suppose $(\mathrm{Id}, [1_X]) \sim (\mathrm{Id}, [T])$ through h, k. Then $[T] \circ h = k \circ [1_X]$, so $[T] = k \circ h^{-1}$ is a generalized isomorphism (cancellation of isomorphisms in the localization). But $[T]$ is the class of a functor, and by Theorem 10.3.10 (Part X) the class of a functor is invertible iff the functor is an equivalence; T is not, not being faithful: it sends the non-trivial isotropy elements to 1 Chapter16/CompositionCounterexample · CompositionCounterexample.not_isEquivalence_T Chapter16/CompositionCounterexample · CompositionCounterexample.not_isIso_T.

Step 6, on classes Chapter16/CompositionCounterexample · CompositionCounterexample.not_exists_comp: no composition of sc-smooth maps agrees with the composite of representatives for all choices, since it would have to equal both classes of Step 5.

The mechanism. It is that of §XVI.2: in Definition 16.1.6 the isomorphism (k, Id_W) of the middle structure is not determined by Id_W, because two generalized isomorphisms of Y with the identity orbit map need not agree. The middle structure is not effective Chapter16/CompositionCounterexample · CompositionCounterexample.not_isEffective_k2.

Proof of the effective form. *Step 1* Chapter16/PolyfoldMaps · PSHom.Equiv.comp_of_isEffective. Let the middle structure (Y', β') be effective, $a \sim a'$ through (h, k) and $b \sim b'$ through (k', l), where k and k' are isomorphisms over the identity $(Y, \beta) \to (Y', \beta')$. By the uniqueness for an effective target (§XVI.2), $k = k'$. Then the two squares paste to one square for the composites, with the outer isomorphisms h and l. *Step 2, composites of representatives* Chapter16/PolyfoldMaps · PolyfoldClass.MapRep.comp: for representatives $(f, \mathfrak{f}) : (X, \alpha) \to (Y, \beta)$ and $(g, \mathfrak{g}) : (Y', \beta') \to (V, \gamma)$ whose middle structures differ, the composite is $(g \circ f, \mathfrak{g} \circ k \circ \mathfrak{f})$ with the chosen isomorphism k of Step 4 of PS. For an effective d it respects the relation Chapter16/PolyfoldMaps · PolyfoldClass.MapRep.comp_equiv, by Step 1 and the uniqueness, which makes the chosen k the only one. *Step 3, effectiveness on classes* Chapter16/PolyfoldMaps · PolyfoldClass.IsEffective Chapter16/PolyfoldMaps · PolyfoldClass.isEffective_iff: a polyfold is effective if one structure is, and then every structure is, since effectiveness is invariant under equivalences of ep-groupoids Chapter16/PolyfoldMaps · EpFunctor.IsEquivalence.isEffective_iff (Remark 10.1.12, through the bijections of isotropy groups) and so under generalized isomorphisms Chapter16/PolyfoldMaps · EPLoc.isEffective_iff_of_isGeneralizedIso. *Step 4, the composite of classes* Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.comp Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.comp_mk: for effective d, the lift of Step 2 to the quotients. *Step 5, the laws* Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.id_comp Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.comp_id Chapter16/PolyfoldMaps · PolyfoldClass.ScMap.comp_assoc: on representatives, with the chosen isomorphisms absorbed by Step 3 of Definition 16.1.6.

Definition 16.1.11 (narrower) Chapter16/PolyfoldMaps · EffPolyfold. Objects are effective polyfolds, morphisms sc-smooth maps, identities $[(\mathrm{Id}_Z, [1_X])]$, and composition from Step 4. *Narrower* because, as we read Definition 16.1.10, the composition is not defined on all polyfolds. Presumably the text intends effective polyfolds, or morphisms carrying a chosen isomorphism of the middle structure; the formalization takes the first. Witness: the one-point polyfold Chapter16/PolyfoldMaps · PolyfoldStructure.pointStructure Chapter16/PolyfoldMaps · EffPolyfold.point, whose ep-groupoid has trivial isotropy and so is effective.

Where Lean departs from the text. The text gives Definitions 16.1.6–16.1.11 without proofs. Three points are made explicit. First, the laws of PS, which hold componentwise once the continuous map is seen to be determined by the generalized map. Second, the composite of two classes: the text composes representatives "with a common middle structure", which leaves open how two representatives are brought to a common middle structure; the formalization does it with a chosen isomorphism over the identity between the two middle structures, and it is exactly there that the choice matters, since another isomorphism over the identity can give an inequivalent composite. Third, the answer to the question "which polyfolds form a category": the effective ones, where Theorem 10.3.19 makes the isomorphism over the identity unique, so that the choice disappears. The counterexample is minimal in the sense that all continuous maps are the identity and all functors are the identity on objects; the only data that differ are the isotropy homomorphisms.

XVI.5 Lemma 16.1.13 (2017: Lemma 16.1), Definitions 16.1.14, 16.1.17 (2017: 16.9, 16.11), Lemma 16.1.19 (2017: Lemma 16.2), Definition 16.1.20 (2017: 16.12), pp. 712–714

Statement. *The degeneracy index of a structure* Chapter16/PolyfoldStructure · PolyfoldStructure.degIndex: $d_{(X,\beta)}(z) = d_{|X|}(\beta^{-1}(z))$. *Lemma 16.1.13* (p. 712, same) Chapter16/PolyfoldStructure · PolyfoldStructure.lemma_16_1_13: equivalent structures have the same degeneracy index. *Definition 16.1.14* (p. 712, same) Chapter16/PolyfoldStructure · PolyfoldClass.degIndex Chapter16/PolyfoldStructure · PolyfoldClass.definition_16_

1_14: $d_Z(z) = d_X(x)$ for every $(X,\beta) \in c$ and $\beta(|x|) = z$. *Definition 16.1.17* (p. 713, same) Chapter16/PolyfoldStructure · PolyfoldClass.boundary: $\partial Z = \{z : d_Z(z) \geq 1\}$. *Lemma 16.1.19* (p. 714, stronger) Chapter16/PolyfoldStructure · PolyfoldStructure.lemma_16_1_19: for equivalent structures, X is tame iff Y is; the text states one direction. *Definition 16.1.20* (p. 714, same) Chapter16/PolyfoldStructure · PolyfoldClass.IsTame Chapter16/PolyfoldStructure · PolyfoldClass.definition_16_1_20: a polyfold is tame if one, and then every, structure in c has X tame.

Proof of Lemma 16.1.13. *Step 1, the index on the orbit space.* $d_{(X,\beta)}(z) = d_X(x)$ for any x with $\beta(|x|) = z$ Chapter16/PolyfoldStructure · PolyfoldStructure.degIndex_eq, because d_X is invariant under morphisms and so descends to $|X|$. *Step 2, invariance.* For a generalized isomorphism $f : X \to Y$, $d_{|Y|} \circ |f| = d_{|X|}$: Proposition 11.1.2 (Part XI), which reduces to the invariance of the degeneracy index under local sc-diffeomorphisms (Part IV) through the legs of a diagram. *Step 3.* If $(X,\alpha) \sim (Y,\beta)$ through f, then $|f| = \beta^{-1} \circ \alpha$ (§XVI.1), so $d_{|Y|}(\beta^{-1}(z)) = d_{|Y|}(|f|(\alpha^{-1}(z))) = d_{|X|}(\alpha^{-1}(z))$.

Proof of Definitions 16.1.14 and 16.1.17. The index of the class is that of its chosen structure, and by Lemma 16.1.13 that of every structure in c. ∂Z is computed in any representative Chapter16/PolyfoldStructure · PolyfoldClass.mem_boundary_iff: $z \in \partial Z$ iff $x \in \partial X$ for one, or every, x with $\beta(|x|) = z$, ∂X being the objects of positive degeneracy index.

Proof of Lemma 16.1.19 and Definition 16.1.20. *Step 1.* Tameness of an ep-groupoid is invariant under equivalences in both directions (Chapter 11, Part XI): an equivalence is a local sc-diffeomorphism on objects, and tameness of an M-polyfold is local and invariant under sc-diffeomorphisms (Part II). *Step 2.* Along a diagram $X \leftarrow A \to Y$, X tame iff A tame iff Y tame. The text states "if X is tame then Y is"; the other direction follows by symmetry of the relation, so the formal statement is the equivalence. *Step 3.* Definition 16.1.20 is "the chosen structure is tame", which by Step 2 is "some, equivalently every, structure is tame".

Not formalized from §16.1. Proposition 16.1.12 (the lifts Z_i and their topology, which the raised polyfolds of §XVI.6 partly cover), Definition 16.1.15 and Remark 16.1.16 (subpolyfolds), Example 16.1.18, Definition 16.1.21 (faces of a polyfold) and Proposition 16.1.22 (§XVI.28).

Where Lean departs from the text. The text proves Lemma 16.1.13 by the invariance of the degeneracy index under generalized isomorphisms, as here; the formalization makes the orbit-space form of the index explicit, $d_{|X|}$, because the structure map β lives on $|X|$. For Lemma 16.1.19 the text proves one direction; the formal statement is an equivalence, which costs one application of the symmetry of Definition 16.1.2. Definition 16.1.17 is stated through the index as printed; the characterization of ∂Z through any representative is a lemma, used in §§XVI.15, XVI.22 and XVI.26 to translate boundary conditions between Z and a model.

XVI.6 The raised polyfolds $(Z,c)^i$ (p. 715)

Statement (restated) Chapter16/RaisedPolyfold · PolyfoldClass.raise. The text defines $(Z,c)^1$ as Z_1 with the structures $(X^1,\alpha|)$. The formalization: $(Z,c)^1$ is the space $|X_0^1|$ for the chosen structure (X_0,α_0) of c Chapter16/RaisedPolyfold · PolyfoldClass.RaisedSpace, with the polyfold class of the structures (X^1,α^1) for $(X,\alpha) \in c$ Chapter16/RaisedPolyfold · PolyfoldClass.raiseStructure, where $\alpha^1 : |X^1| \to |X_0^1|$ Chapter16/RaisedPolyfold · PolyfoldClass.raiseMap is induced by the raise of a generalized isomorphism realizing $(X,\alpha) \sim (X_0,\alpha_0)$. An injective continuous map $(Z,c)^1 \to Z$ has image $Z_1 = \beta(|X|_1)$ for every $(X,\beta) \in c$ Chapter16/RaisedPolyfold · PolyfoldClass.range_raiseIncl. $(Z,c)^i$ is the i-fold raise Chapter16/

RaisedPolyfold · PolyfoldClass.raiseN. *Restated* because $(Z,c)^1$ is a space with an injection into Z, not the subspace Z_1: its topology is that of $|X^1|$, which is finer than the subspace topology. The text means the former (the structure of X^1 carries its own topology); the formalization makes that explicit.

Proof. *Step 1, raising functors.* The index raise $X \mapsto X^1$ of Chapter 7 is functorial on equivalences and functors Chapter16/RaisedPolyfold · EpFunctor.liftOne_comp Chapter16/RaisedPolyfold · EpFunctor.liftOne_id, and the orbit map of Φ^1 is the restriction of that of Φ to $|X^1| \subseteq |X|$ Chapter16/RaisedPolyfold · EpFunctor.orbitIncl_orbitMap_liftOne.

Step 2, raising diagrams. A diagram $X \xleftarrow{F} A \xrightarrow{\Phi} Y$ raises to $X^1 \xleftarrow{F^1} A^1 \xrightarrow{\Phi^1} Y^1$ Chapter16/RaisedPolyfold · EPLocalization.Diagram.liftOne, the raise of an equivalence being an equivalence. Refinements raise to refinements Chapter16/RaisedPolyfold · EPLocalization.Diagram.IsRefinement.liftOne, including the identity refinement and composites Chapter16/RaisedPolyfold · EPLocalization.Diagram.isRefinement_liftOne_id Chapter16/RaisedPolyfold · EPLocalization.Diagram.isRefinement_liftOne_comp, because the weak fibre product of Chapter 10 commutes with the raise; so equivalent diagrams raise to equivalent diagrams Chapter16/RaisedPolyfold · EPLocalization.Diagram.Equiv.liftOne, and the orbit maps restrict Chapter16/RaisedPolyfold · EPLocalization.Diagram.orbitIncl_orbitMap_liftOne.

Step 3, raising generalized maps Chapter16/RaisedPolyfold · EPLocalization.EPLoc.liftOneHom: by Step 2 the raise is well defined on the localization, with $1^1 = 1$ and $(\mathfrak{g}\circ\mathfrak{f})^1 = \mathfrak{g}^1 \circ \mathfrak{f}^1$ Chapter16/RaisedPolyfold · EPLocalization.EPLoc.liftOneHom_id Chapter16/RaisedPolyfold · EPLocalization.EPLoc.liftOneHom_comp, so it keeps generalized isomorphisms Chapter16/RaisedPolyfold · EPLocalization.EPLoc.isGeneralizedIso_liftOneHom, and $|\mathfrak{f}^1| = |\mathfrak{f}|$ on $|X^1|$ Chapter16/RaisedPolyfold · EPLocalization.EPLoc.orbitIncl_orbitMap_liftOneHom. Two generalized maps with the same orbit map have raises with the same orbit map Chapter16/RaisedPolyfold · EPLocalization.EPLoc.orbitMap_liftOneHom_eq, because $|X^1| \to |X|$ is injective.

Step 4, the raised structure is a polyfold structure. X^1 has a paracompact orbit space Chapter16/RaisedPolyfold · PolyfoldStructure.liftOne_paracompact: $|X^1|$ is metrizable by Proposition 7.5.3 (Part VII), since X^1 is again an ep-groupoid. X^1 satisfies (ZHOU) Chapter16/RaisedPolyfold · PolyfoldStructure.liftOne_isZhou, by Propositions 7.4.8 and 7.4.9 (Part VII): the natural representations of X^1 are restrictions of those of X, and the sets Fix and their interiors behave under the raise as the propositions state.

Step 5, the maps α^1. For $(X,\alpha) \in c$, $\alpha^1 = |\mathfrak{f}^1|$ for a generalized isomorphism $\mathfrak{f}$ with $\alpha_0 \circ |\mathfrak{f}| = \alpha$; it does not depend on $\mathfrak{f}$ by Step 3 Chapter16/RaisedPolyfold · PolyfoldClass.raiseMap_eq, is compatible with composition Chapter16/RaisedPolyfold · PolyfoldClass.raiseMap_comp, and is a homeomorphism Chapter16/RaisedPolyfold · PolyfoldClass.isHomeomorph_raiseMap Chapter16/RaisedPolyfold · PolyfoldClass.raiseHomeomorph, being the orbit map of a generalized isomorphism. So (X^1,α^1) is a polyfold structure on $(Z,c)^1$, and all of them are equivalent through the raised isomorphisms Chapter16/RaisedPolyfold · PolyfoldClass.raiseStructure_equiv; the class does not depend on the representative it is built from Chapter16/RaisedPolyfold · PolyfoldClass.raise_eq.

Step 6, the inclusion. $(Z,c)^1 \to Z$ is $\alpha_0 \circ \iota$ with $\iota : |X_0^1| \to |X_0|$ Chapter16/RaisedPolyfold · PolyfoldClass.raiseIncl; it is injective Chapter16/RaisedPolyfold · PolyfoldClass.raiseIncl_injective (orbits of X^1 are orbits of X through level-1 points) and continuous Chapter16/RaisedPolyfold · PolyfoldClass.continuous_raiseIncl, it satisfies $\mathrm{incl} \circ \alpha^1 = \alpha \circ \iota$ for every structure Chapter16/RaisedPolyfold · PolyfoldClass.raiseIncl_raiseMap, and its image is Z_1 by Step 3. *Step 7, iteration.* $(Z,c)^0 = (Z,c)$ Chapter16/RaisedPolyfold · PolyfoldClass.raiseN_zero and $(Z,c)^{i+1} = ((Z,c)^i)^1$ Chapter16/RaisedPolyfold · PolyfoldClass.raiseN_succ, with the space and class carried together Chapter16/RaisedPolyfold · PolyfoldClass.PolyfoldPair. The text's index notation mI is not introduced; $Z_i = \alpha(|X_i|)$ for every structure.

Where Lean departs from the text. The text defines the raised polyfold by restricting each structure (X, α) to X^1 and gluing; that the restricted pairs are polyfold structures, and that they are equivalent, is left implicit. The formalization proves both: paracompactness through Proposition 7.5.3, (ZHOU) through Propositions 7.4.8 and 7.4.9, and the equivalence through the raise of generalized isomorphisms, which needs the raise to commute with weak fibre products so that refinements raise to refinements. The topology is the second point: the text writes $(Z, c)^1$ for a space whose underlying set is Z_1, and the formalization keeps the topology of $|X^1|$ rather than the subspace topology of $Z_1 \subseteq Z$, since only the former makes α^1 a homeomorphism; the inclusion into Z is continuous and injective but in general not an embedding.

XVI.7 Lemma 16.2.1 (2017: Lemma 16.3), p. 716: isomorphisms of polyfold structures and their tangents

Statement (does not hold as we read it; its orbit form and its form for an effective target hold). The text: if two isomorphisms $(f, \mathfrak{f}), (g, \mathfrak{g}) : (X, \alpha) \to (Y, \beta)$ of polyfold structures have $f = g$, then $\mathfrak{f} = \mathfrak{g}$ and $T\mathfrak{f} = T\mathfrak{g}$. Its proof: $|\mathfrak{f}| = |\mathfrak{g}|$, then Theorem 10.3.19. The statement in Lean `Chapter16/TangentLemma · PolyfoldStructure.Lemma_16_2_1`: f, g homeomorphisms, $\mathfrak{f}$, $\mathfrak{g}$ generalized isomorphisms with $f \circ \alpha = \beta \circ |\mathfrak{f}|$ and $g \circ \alpha = \beta \circ |\mathfrak{g}|$, and $f = g$; conclusion $\mathfrak{f} = \mathfrak{g}$ and $T\mathfrak{f} = T\mathfrak{g}$. It does not hold as we read it `Chapter16/TangentLemma · PolyfoldStructure.not_lemma_16_2_1`. *The orbit form* `Chapter16/TangentLemma · PolyfoldStructure.lemma_16_2_1_orbit`, under exactly the text's hypotheses: $|\mathfrak{f}| = |\mathfrak{g}|$ and $|T\mathfrak{f}| = |T\mathfrak{g}|$. *The effective form* `Chapter16/TangentLemma · PolyfoldStructure.lemma_16_2_1_of_isEffective`: if Y is effective, the text's conclusion holds.

The tangent of a generalized map. For $\mathfrak{f} = [X \xleftarrow{F} A \xrightarrow{\Phi} Y]$, $T\mathfrak{f}$ is the class of $[TX \xleftarrow{TF} TA \xrightarrow{T\Phi} TY]$ `Chapter16/TangentLemma · EPLocalization.EPLoc.tangentHom`. *Step 1.* The tangent of an ep-groupoid (Theorem 8.1.1, Part VIII) is taken in any universe `Chapter16/TangentLemma · EP.tangentAny`, and agrees with Chapter 8's where both are defined. *Step 2.* The tangent of a diagram is a diagram, since the tangent of an equivalence is an equivalence (Theorem 10.1.7, Part X) `Chapter16/TangentLemma · EPLocalization.Diagram.tangentAny`. *Step 3.* Refinements go to refinements `Chapter16/TangentLemma · EPLocalization.Diagram.IsRefinement.tangentAny`, compatibly with composition of refinements `Chapter16/TangentLemma · EPLocalization.Diagram.isRefinement_tangentAny_comp`, so equivalent diagrams have equivalent tangents `Chapter16/TangentLemma · EPLocalization.Diagram.Equiv.tangentAny`. *Step 4.* The result is a copy of Chapter 11's tangent functor on the localization `Chapter16/TangentLemma · EPLocalization.EPLoc.tangentHom_eq_tangentFunctor_map`, compatible with identities and composition `Chapter16/TangentLemma · EPLocalization.EPLoc.tangentHom_id` `Chapter16/TangentLemma · EPLocalization.EPLoc.tangentHom_comp`, and it preserves generalized isomorphisms `Chapter16/TangentLemma · EPLocalization.EPLoc.isGeneralizedIso_tangentHom`.

Proof that the lemma does not hold as we read it. *The example* `Chapter16/TangentLemma · PolyfoldStructure.lemma_16_2_1_counterexample` is the pair of §XVI.2. On the polyfold structure $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$ of $\mathbb{R}$ with the trivial action, take $f = g = \mathrm{id}$, $\mathfrak{f} = [X \xleftarrow{1} X \xrightarrow{\mathrm{Inv}} X]$ and $\mathfrak{g} = [1_X]$. Both squares commute, since both orbit maps are the identity; the orbit space is paracompact; (ZHOU) holds; $f = g$; and $\mathfrak{f} \neq \mathfrak{g}$ (§XVI.2, Step 4). The last step of the text's proof is Theorem 10.3.19, which does not hold as we read it `Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.not_theorem_10_3_19` (Part X). Whether $T\mathfrak{f} \neq T\mathfrak{g}$ in this example is not decided; their orbit maps agree, by the orbit form.

Proof of the orbit form. *Step 1* `Chapter16/TangentLemma · PolyfoldStructure.orbitMap_eq_of_comp`: $|\mathfrak{f}| = \beta^{-1} \circ f \circ \alpha$,

so $f = g$ gives $|\mathfrak{f}| = |\mathfrak{g}|$.

Step 2, reduction to an automorphism Chapter16/TangentLemma · EPLocalization.EPLoc.orbitMap_tangentHom_eq: if X or Y has (LR) and $|\mathfrak{f}| = |\mathfrak{g}|$, then $|T\mathfrak{f}| = |T\mathfrak{g}|$. With $\mathfrak{g}'$ an inverse of $\mathfrak{f}$, $e = \mathfrak{g}' \circ \mathfrak{g}$ is a generalized automorphism of X with $|e| = |\mathfrak{f}|^{-1} \circ |\mathfrak{g}| = 1$ (Proposition 10.3.11), and $\mathfrak{g} = \mathfrak{f} \circ e$; since T is a functor, $|T\mathfrak{g}| = |T\mathfrak{f}| \circ |Te|$, and it suffices that $|Te| = 1$. If only Y has (LR), the same argument runs with $\mathfrak{g} \circ \mathfrak{f}^{-1}$, an automorphism of Y.

Step 3, the automorphism Chapter16/TangentLemma · EPLocalization.EPLoc.orbitMap_tangentHom_eq_id. Represent e by a diagram $X \xleftarrow{F} A \xrightarrow{\Phi} X$ of equivalences; $|e| = 1$ says $|F| = |\Phi|$. A has (LR) by Proposition 10.1.9 (Part X), being equivalent to X. By Proposition 10.1.10 (1), two functors $A \to X$ with the same orbit map from an ep-groupoid with (LR) are connected locally by families of morphisms, and by Proposition 10.1.10 (2) these give $|TF| = |T\Phi|$, that is $|Te| = 1$.

Step 4. (ZHOU) gives (LR) for X (§XVI.1), so Steps 2–3 apply to every polyfold structure.

Proof of the effective form. If Y is effective, then $\mathfrak{f} = \mathfrak{g}$ by Remark 16.1.7 for an effective target (§XVI.2), and so $T\mathfrak{f} = T\mathfrak{g}$. Its hypotheses are satisfiable Chapter16/TangentLemma · PolyfoldStructure.lemma_16_2_1_of_isEffective_hypotheses: the point ep-groupoid is effective and satisfies (ZHOU).

What the rest of §16.2 needs. Only the orbit form: the gluing of $T(Z, c)$ uses the maps $|T\mathfrak{f}|$ (§XVI.8), and the remark before Definition 16.2.5 uses the analogous statement for forms (§XVI.10).

Where Lean departs from the text. The text's proof has two steps: $|\mathfrak{f}| = |\mathfrak{g}|$, then Theorem 10.3.19 for $\mathfrak{f} = \mathfrak{g}$, from which $T\mathfrak{f} = T\mathfrak{g}$ is immediate. The formalization keeps the first step, replaces the second by Proposition 10.1.10 at the level of tangent orbit maps, and proves the conclusion on orbit spaces only. For the tangent conclusion this is a genuinely different route: it never compares $\mathfrak{f}$ with $\mathfrak{g}$, only their effect on orbits, and it needs only (LR), which (ZHOU) gives. The full conclusion is recovered for an effective target, through the effective Theorem 10.3.19.

XVI.8 The tangent $T(Z, c)$, (16.5), Lemma 16.2.2, Definition 16.2.3 (2017: Lemma 16.4, Definition 16.14), and the projection τ_Z, pp. 716–719

Statement. *The construction* (pp. 716–718, same, with a base structure in place of the gluing; decision (3)): $T(Z, c) = |TX_0|$ for the chosen structure (X_0, α_0) of c Chapter16/TangentPolyfold · PolyfoldClass.TangentSpace, with the orbit space topology Chapter16/TangentPolyfold · PolyfoldClass.tangentSpaceTopology; for $(X, \alpha) \in c$, $T\alpha = |T\mathfrak{f}| : |TX| \to T(Z, c)$ for a generalized isomorphism $\mathfrak{f} : X \to X_0$ with $\alpha_0 \circ |\mathfrak{f}| = \alpha$ Chapter16/TangentPolyfold · PolyfoldClass.tangentMap. *(16.5)* (same) Chapter16/TangentPolyfold · PolyfoldClass.tangentMap_comp: $T\beta \circ |Th| = T\alpha$ for every generalized isomorphism $h : X \to Y$ with $\beta \circ |h| = \alpha$. *Lemma 16.2.2* (p. 718, same) Chapter16/TangentPolyfold · PolyfoldClass.lemma_16_2_2: (1) every $T\alpha$ is a homeomorphism; (2) the topology of $T(Z, c)$ is the unique one for which one, and then every, $T\alpha$ is a homeomorphism; (3) $T(Z, c)$ is metrizable. *Definition 16.2.3* (p. 719, restated) Chapter16/TangentPolyfold · PolyfoldClass.tangent Chapter16/TangentPolyfold · PolyfoldClass.definition_16_2_3: the tangent $(T(Z, c), Tc)$ is the polyfold whose class contains every $(TX, T\alpha)$, $(X, \alpha) \in c$. *The projection* (p. 717, restated) Chapter16/RaisedPolyfold · PolyfoldClass.tangentProj: $\tau_Z : T(Z, c) \to (Z, c)^1$ with $\tau_Z \circ T\alpha = \alpha^1 \circ |\tau_X|$.

Proof of the construction. *Step 1, $T\alpha$ does not depend on $\mathfrak{f}$* Chapter16/TangentPolyfold · PolyfoldClass.

`tangentMap_eq`. Two generalized isomorphisms $\mathfrak{f}, \mathfrak{f}'$ with $\alpha_0 \circ |\mathfrak{f}| = \alpha = \alpha_0 \circ |\mathfrak{f}'|$ have the same orbit map $\alpha_0^{-1} \circ \alpha$, hence the same $|T\mathfrak{f}|$ by the orbit form of Lemma 16.2.1 (§XVI.7, Steps 2–3). The text says "the unique $\mathfrak{f}$"; $\mathfrak{f}$ need not be unique (§XVI.2), but $|T\mathfrak{f}|$ is, and it is all that the construction uses. *Step 2, (16.5).* Let $\mathfrak{f}_Y : Y \to X_0$ realize (Y, β). Then $\mathfrak{f}_Y \circ h$ realizes (X, α), since $\alpha_0 \circ |\mathfrak{f}_Y| \circ |h| = \beta \circ |h| = \alpha$. By Step 1, $T\alpha = |T(\mathfrak{f}_Y \circ h)| = |T\mathfrak{f}_Y| \circ |Th| = T\beta \circ |Th|$, using that T is a functor on the localization (§XVI.7). *Step 3, homeomorphisms* `Chapter16/TangentPolyfold · PolyfoldClass.isHomeomorph_tangentMap` `Chapter16/TangentPolyfold · PolyfoldClass.tangentHomeomorph`: the orbit map of a generalized isomorphism is a homeomorphism `Chapter16/TangentPolyfold · EPLocalization.EPLoc.isHomeomorph_orbitMap_of_isGeneralizedIso` (its inverse is the orbit map of the inverse, by Proposition 10.3.11), and $T\mathfrak{f}$ is a generalized isomorphism.

Proof of Lemma 16.2.2. (1) is Step 3. (2): if τ is a topology on the set $T(Z, c)$ for which some $T\alpha$ is a homeomorphism, then the open sets of τ are exactly the sets whose preimage under $T\alpha$ is open in $|TX|$; the same holds for the given topology by (1); so the two agree. Since all $T\alpha$ are homeomorphisms for the given topology, "one" and "every" agree. (3): Theorem 8.1.15 (Part VIII) makes $|TX_0|$ metrizable `Chapter8/TangentOrbit · metrizableSpace_tangent_orbitSpace`.

Proof of Definition 16.2.3. *Step 1, $(TX, T\alpha)$ is a polyfold structure* `Chapter16/TangentPolyfold · PolyfoldClass.tangentStructure`. $|TX|$ is paracompact by Theorem 8.1.15 `Chapter16/TangentPolyfold · PolyfoldStructure.tangent_paracompact` `Chapter8/TangentOrbit · theorem_8_1_15`, and TX satisfies (ZHOU) by Proposition 8.1.16 in its 2021 form `Chapter16/TangentPolyfold · PolyfoldStructure.tangent_isZhou` `Chapter8/TangentZhouReflect2021 · proposition_8_1_16_2021` (Part VIII). *Step 2, they are equivalent* `Chapter16/TangentPolyfold · PolyfoldClass.tangentStructure_equiv`: for $h : X \to Y$ with $\beta \circ |h| = \alpha$, Th is a generalized isomorphism with $T\beta \circ |Th| = T\alpha$ by (16.5). *Step 3.* Tc is the class of $(TX_0, T\alpha_0)$, and by Step 2 every $(TX, T\alpha)$ lies in it. *Readings.* $T(Z, c)$ lives one universe up, as TX does in Chapter 8. "Restated" because the text defines $T(Z, c)$ as a disjoint union modulo identifications; the base structure gives a canonically homeomorphic space (Lemma 16.2.2 (2)).

Proof of the projection τ_Z. *Step 1, naturality of τ for functors* `Chapter16/RaisedPolyfold · EpFunctor.orbitMap_tangentProj_tangent`: for a functor Φ, $|\tau_Y| \circ |T\Phi| = |\Phi^1| \circ |\tau_X|$, from the pointwise identity $\tau \circ T\Phi = \Phi^1 \circ \tau$ on objects. *Step 2, for diagrams and generalized maps* `Chapter16/RaisedPolyfold · EPLocalization.Diagram.orbitMap_tangentProj_tangentAny` `Chapter16/RaisedPolyfold · EPLocalization.EPLoc.orbitMap_tangentProj_tangentHom`: through both legs, with the raised generalized maps of §XVI.6. *Step 3, the definition*: $\tau_Z = |\tau_{X_0}| : |TX_0| \to |X_0^1|$; it is continuous `Chapter16/RaisedPolyfold · PolyfoldClass.continuous_tangentProj`, and for every $(X, \alpha) \in c$, $\tau_Z \circ T\alpha = \alpha^1 \circ |\tau_X|$ `Chapter16/RaisedPolyfold · PolyfoldClass.tangentProj_tangentMap` by Step 2 applied to a realizing $\mathfrak{f}$. Composed with the inclusion $(Z, c)^1 \to Z$, it is the text's square into Z `Chapter16/RaisedPolyfold · PolyfoldClass.raiseIncl_tangentProj_tangentMap`.

Where Lean departs from the text. The text constructs $T(Z, c)$ as the disjoint union of the $|TX|$ over all $(X, \alpha) \in c$, modulo the identifications by $|T\mathfrak{f}|$ for the unique $\mathfrak{f}$, and Lemma 16.2.2 then puts a topology on the quotient. The formalization takes one structure as base point and defines $T\alpha$ as a map into it; the identifications of the text become the identity (16.5), and Lemma 16.2.2 (2) shows that the base point does not matter topologically. The two constructions give canonically homeomorphic spaces. The uniqueness of $\mathfrak{f}$, which the text uses to make the identifications consistent, is replaced by the uniqueness of $|T\mathfrak{f}|$, which is what consistency of the identifications needs. The projection τ_Z is built the same way, as $|\tau_{X_0}|$ with a naturality square for every structure.

XVI.9 Theorem 16.2.4 (2017: Theorem 16.1), p. 719: the tangent functor

Statement (narrower). *On PS* `Chapter16/TangentFunctor · PSCat.tangentFunctor`: $(X,\alpha) \mapsto (TX, T\alpha)$ and $(f,\mathfrak{f}) \mapsto (Tf, T\mathfrak{f})$ is a functor from PS to PS one universe up. *On sc-smooth maps* `Chapter16/TangentFunctor · PolyfoldClass.theorem_16_2_4`: $T\hat{f} = [(Tf, T\mathfrak{f})]$ is well defined for every sc-smooth map between any polyfolds, with $Tf \circ T\alpha = T\beta \circ |T\mathfrak{f}|$, and $T1 = 1$. *On effective polyfolds* `Chapter16/TangentEffective · theorem_16_2_4_eff`: T is a functor on the category of effective polyfolds `Chapter16/TangentEffective · EffPolyfold.tangentFunctor`. *Narrower* because there is no category of all polyfolds as we read Definition 16.1.10 (§XVI.4); on effective polyfolds, where the composite is defined, it is the text's statement with no added hypothesis.

Proof on PS. *Step 1.* A generalized map alone determines a morphism of PS one universe up `Chapter16/TangentFunctor · PSHom.ofGen'`, compatibly with composition `Chapter16/TangentFunctor · PSHom.ofGen'_comp`: its continuous map is forced by Step 1 of PS (§XVI.4). *Step 2.* $T(X,\alpha)$ is the structure $(TX, T\alpha)$ on $|TX|$ itself, with $T\alpha$ the identity of $|TX|$ for the structure taken as its own base `Chapter16/TangentFunctor · PolyfoldStructure.tangentSelf`, and the functor laws are those of T on the localization (§XVI.7). *Step 3.* Isomorphisms over the identity go to isomorphisms over the identity `Chapter16/TangentFunctor · PolyfoldClass.tangent_isIdIso`, by (16.5).

Proof on sc-smooth maps. *Step 1, representatives* `Chapter16/TangentFunctor · PolyfoldClass.MapRep.tangent`: for a representative $(f,\mathfrak{f}) : (X,\alpha) \to (Y,\beta)$, $(Tf, T\mathfrak{f}) : (TX, T\alpha) \to (TY, T\beta)$ with $Tf = T\beta \circ |T\mathfrak{f}| \circ (T\alpha)^{-1}$. *Step 2, well defined* `Chapter16/TangentFunctor · PolyfoldClass.MapRep.tangent_equiv`: a square $(f',\mathfrak{f}') \circ (h, \mathrm{Id}) = (k, \mathrm{Id}) \circ (f,\mathfrak{f})$ goes under T to a square with the isomorphisms over the identity (Th, Id) and (Tk, Id), by Step 3 on PS. No effectiveness is used, because Definition 16.1.6 carries h and k as data. *Step 3, the class* `Chapter16/TangentFunctor · PolyfoldClass.ScMap.tangent` with its map determined by $Tf \circ T\alpha = T\beta \circ |T\mathfrak{f}|$ `Chapter16/TangentFunctor · PolyfoldClass.ScMap.tangent_toFun` `Chapter16/TangentFunctor · PolyfoldClass.ScMap.tangent_mk`. *Step 4.* $T1 = 1$ `Chapter16/TangentFunctor · PolyfoldClass.ScMap.tangent_id`, since $T[1_X] = [1_{TX}]$; and the tangent of a composite of representatives is the composite of the tangents `Chapter16/TangentFunctor · PolyfoldClass.ScMap.tangent_mk_comp`. *Step 5, composites of classes.* For an effective middle polyfold d whose tangent is effective, $T(\hat{g} \circ \hat{f}) = T\hat{g} \circ T\hat{f}$ `Chapter16/TangentFunctor · PolyfoldClass.ScMap.tangent_comp`: the composite on the right is defined only if Td is effective, which the next proof supplies.

The tangent of an effective ep-groupoid with (ZHOU) is effective `Chapter16/TangentEffective · EpGroupoid.isEffective_tangentEpGroupoid`. *Statement:* for X effective with (ZHOU), the tangent ep-groupoid TX (Theorem 8.1.1) is effective (Definition 7.2.1). This is not printed; the text uses it implicitly when it calls T a functor on the polyfold category.

Proof. Suppose an isotropy element g of TX at a tangent vector a, $g \neq 1$, acts trivially near a: there is an open $W \ni a$ in the object space of TX on which the local diffeomorphism of g is the identity.

Step 1, the base morphism is not a unit. Let $\varphi \in X$ be the base morphism of g (the morphism of X under the tangent morphism g, which acts on $T_{s(\varphi)}X$ by $T\varphi$). If φ were a unit, then g would be a unit `Chapter16/TangentEffective · EpGroupoid.tangent_isotropy_eq_one`, since a tangent morphism over a unit with the same source and target is the unit. So $\varphi \neq 1$.

Step 2, separation. The morphism space is Hausdorff, so choose disjoint open sets $A \ni \varphi$ and $B \ni 1_{s(\varphi)}$.

Step 3, a sheet of the source map. s is a local sc-diffeomorphism at φ; let σ be its local inverse on a neighbourhood V of $s(\varphi)$, with $\sigma(s(\varphi)) = \varphi$, and $T\sigma$ its tangent.

Step 4, an open set of tangent vectors. Let $W_0 \subseteq W$ be the tangent vectors whose base morphism lies in A, in the sheet, and has source whose unit lies in B, and let O be the set of tangent vectors b over V with $T\sigma(b) \in W_0$. O is open in TX and contains a.

Step 5, a smooth point. O is open in TX, whose topology is that of level 1; smooth points are dense, so pick $b \in O$ over a smooth point. Its base point $x = \tau(b)$ lies in X_∞ `Chapter16/TangentEffective · EpGroupoid.levelVal_tangentProj_mem_smoothSet`, because the projection $TX \to X^1$ is sc-smooth and $(X^1)_\infty = X_\infty$.

Step 6, the morphism at x. Put $\psi = \sigma(x)$, a morphism of X from x, lying in A. By the choice of W_0, the tangent morphism $T\psi$ acts as the identity on an open set of T_xX around b, through the triviality of g's action on W transported along the sheet.

Step 7, linearity. $T\psi : T_xX \to T_{t(\psi)}X$ is linear and equals the identity on an open subset of the fibre, so $T\psi = \mathrm{id}$ on the whole fibre and $t(\psi) = x$ `Chapter16/TangentEffective · linearMap_eq_self_of_eqOn_isOpen`.

Step 8, (ZHOU) and effectiveness. $\psi \in G_x$ with $T_x\psi = \mathrm{id}$ at the smooth point x; (ZHOU) says that then ψ acts as the identity near x, and effectiveness of X gives $\psi = 1_x$. But $\psi \in A$ and $1_x \in B$, with $A \cap B = \emptyset$. This contradiction shows $g = 1$.

Why both hypotheses. Effectiveness of X is a statement at level 0, while open sets of TX see only level 1; an isotropy element acting trivially near a tangent vector must first be moved to a smooth point, where (ZHOU) converts the triviality of the linearized action into triviality near the point. **For polyfolds** `Chapter16/TangentEffective · PolyfoldClass.IsEffective.tangent`: the tangent of an effective polyfold is effective, since (ZHOU) is part of every polyfold structure (Definition 16.1.1 (2)); no hypothesis is added.

Proof on effective polyfolds. *Step 1* `Chapter16/TangentEffective · EffPolyfold.tangent`: an effective polyfold has an effective tangent, an object of the category. *Step 2* `Chapter16/TangentEffective · PolyfoldClass.ScMap.tangent_comp_of_isEffective`: $T(\hat{g} \circ \hat{f}) = T\hat{g} \circ T\hat{f}$ whenever the middle polyfold is effective, from Step 5 of the previous proof with the effectiveness of Td supplied by the theorem above. *Step 3*: with $T1 = 1$ this is a functor, and with $Tf \circ T\alpha = T\beta \circ |T\mathfrak{f}|$ it is Theorem 16.2.4.

Where Lean departs from the text. The text states Theorem 16.2.4 for the polyfold category of Definition 16.1.11 and treats functoriality as evident from the functoriality of T on generalized maps. The formalization proves it at three levels: on PS, where it is the functoriality on the localization; on sc-smooth maps of all polyfolds, where well-definedness needs only that Definition 16.1.6 carries its isomorphisms as data; and on the category of effective polyfolds, where composites are defined. At the third level a statement the text does not print is needed, that the tangent of an effective polyfold is effective, since otherwise the tangent of a morphism of effective polyfolds would not be a morphism of the category. Its proof is new, and it uses (ZHOU), part of every polyfold structure, in an essential way.

XVI.10 The remark before Definition 16.2.5, Definition 16.2.5 and Theorem 16.2.6 (2017: Definition 16.15, Theorem 16.2), pp. 720–721: sc-differential forms

Statement. *The remark* (p. 720, same) `Chapter16/FormsIndependence · EPLocalization.EPLoc.formsPush_eq_of_orbitMap_eq_or`: for generalized isomorphisms $h, h' : X \to Y$ with $|h| = |h'|$, $h_* = h'_*$ on $\Omega^k_{ep,\infty}$ if X or Y has (LR); likewise for pull-backs `Chapter16/FormsIndependence · EPLocalization.EPLoc.formsPullback_eq_of_orbitMap_eq_or`. *Definition 16.2.5* (p. 720, restated) `Chapter16/PolyfoldForms · PolyfoldClass.ScForm`: $\Omega^k_{sc}(Z, c)$

is the set of classes of pairs $(\omega,(X,\alpha))$. *Theorem 16.2.6* (p. 721, same), in two parts: the complex Chapter16/PolyfoldForms · PolyfoldClass.theorem_16_2_6_complex and the pull-back by sc-smooth maps Chapter16/FormsPullback · PolyfoldClass.theorem_16_2_6_pullback.

Proof of the remark. It is Proposition 11.2.9 (Part XI) Chapter11/OrbitForms · formsPush_eq_of_orbitMap_eq, which takes (LR) on the source; with (LR) on the target, Proposition 10.3.16 moves it to the source, being invariant under equivalences. For polyfold structures (ZHOU) gives (LR) (§XVI.1), so $h_*\omega$ depends only on α and β, since $|h| = \beta^{-1}\circ\alpha$. The mechanism is that of §XVI.7: generalized isomorphisms with one orbit map differ by an automorphism with trivial orbit map, which acts trivially on forms by Proposition 10.1.10. Pull-back by a generalized isomorphism is push-forward by its inverse Chapter16/PolyfoldForms · EPLocalization.EPLoc.formsPush_eq_formsPullback.

Proof of Definition 16.2.5. *Step 1, representatives* Chapter16/PolyfoldForms · PolyfoldClass.FormRep: pairs $(\omega,(X,\alpha))$ with $(X,\alpha)\in c$ and $\omega\in\Omega^k_{ep,\infty}(X)$. *Step 2, the relation* Chapter16/PolyfoldForms · PolyfoldClass.FormRep.Rel: $(\omega,(X,\alpha))\sim(\omega',(Y,\beta))$ if $\omega' = h_*\omega$ for some, equivalently (by the remark) every, generalized isomorphism h with $\beta\circ|h| = \alpha$. *Step 3, an equivalence relation*: reflexive by $1_* = 1$ Chapter16/PolyfoldForms · EPLocalization.EPLoc.formsPush_id Chapter16/PolyfoldForms · PolyfoldClass.FormRep.Rel.refl (Theorem 11.2.1 (3), Part XI), symmetric by $(h^{-1})_* = (h_*)^{-1}$ Chapter16/PolyfoldForms · PolyfoldClass.FormRep.Rel.symm, transitive by $(h'\circ h)_* = h'_*\circ h_*$ Chapter16/PolyfoldForms · EPLocalization.EPLoc.formsPush_comp, with composites and identities of generalized isomorphisms again generalized isomorphisms Chapter16/PolyfoldForms · EPLocalization.EPLoc.isGeneralizedIso_comp Chapter16/PolyfoldForms · EPLocalization.EPLoc.isGeneralizedIso_id. *Step 4, classes* Chapter16/PolyfoldForms · PolyfoldClass.ScForm.mk, injective on each structure Chapter16/PolyfoldForms · PolyfoldClass.ScForm.mk_injective, and related through push-forward Chapter16/PolyfoldForms · PolyfoldClass.ScForm.mk_eq_mk_formsPush. *Step 5, the representative on a structure* Chapter16/PolyfoldForms · PolyfoldClass.ScForm.toStructure: for $(X,\alpha)\in c$ and a class τ, the unique ω with $\tau = [(\omega,(X,\alpha))]$, obtained by pushing any representative along a realizing isomorphism Chapter16/PolyfoldForms · PolyfoldClass.ScForm.exists_iso Chapter16/PolyfoldForms · PolyfoldClass.ScForm.formsPush_eq Chapter16/PolyfoldForms · PolyfoldClass.ScForm.repOn. This gives a bijection $\Omega^k_{sc}(Z,c)\cong\Omega^k_{ep,\infty}(X)$ Chapter16/PolyfoldForms · PolyfoldClass.ScForm.equivStructure, and representatives on related structures are related by pull-back Chapter16/BranchedSuborbifold · PolyfoldClass.ScForm.toStructure_eq_formsPullback. *Step 6, the vector space structure.* It is transported from the chosen structure Chapter16/PolyfoldForms · PolyfoldClass.ScForm.out and satisfies the text's formulas for every representative: $[(\omega,q)]+[(\omega',q)] = [(\omega+\omega',q)]$ Chapter16/PolyfoldForms · PolyfoldClass.ScForm.mk_add and $r[(\omega,q)] = [(r\omega,q)]$ Chapter16/PolyfoldForms · PolyfoldClass.ScForm.mk_smul Chapter16/PolyfoldForms · PolyfoldClass.ScForm.mk_add_smul, because h_* is linear. So each bijection of Step 5 is linear Chapter16/PolyfoldForms · PolyfoldClass.ScForm.toStructure Chapter16/PolyfoldForms · PolyfoldClass.ScForm.equivStructure. *Restated* because the text's representatives are written $(\omega,(X,\alpha))$ informally and the vector space operations on classes are defined by these formulas; the formalization defines them on one structure and proves the formulas.

Proof of Theorem 16.2.6, the complex. *Step 1, d on representatives* Chapter16/PolyfoldForms · PolyfoldClass.ScForm.dRep Chapter16/PolyfoldForms · PolyfoldClass.ScForm.dFun: $d[(\omega,(X,\alpha))] = [(d\omega,(X,\alpha))]$. *Step 2, well defined* Chapter16/PolyfoldForms · PolyfoldClass.ScForm.formsPush_d: h_* commutes with d for a generalized isomorphism (Theorem 11.2.1, Part XI), so related representatives have related differentials. *Step 3, the operator* Chapter16/PolyfoldForms · PolyfoldClass.ScForm.d Chapter16/PolyfoldForms · PolyfoldClass.ScForm.d_apply is linear, and the formula holds for every $(X,\alpha)\in c$ Chapter16/PolyfoldForms · PolyfoldClass.ScForm.d_mk. *Step 4, $d\circ d = 0$* Chapter16/PolyfoldForms · PolyfoldClass.ScForm.d_d Chapter16/PolyfoldForms · PolyfoldClass.ScForm.d_comp_d, from $d\circ d = 0$ on $\Omega^*_{ep,\infty}(X)$ (Part XI). *Step 5.* $\omega\mapsto[(\omega,(X,\alpha))]$ is a linear isomorphism of complexes.

Proof of Theorem 16.2.6, the pull-back. *Statement:* an sc-smooth map $\widehat{f} : (Z, c) \to (W, d)$ pulls back forms by $\widehat{f}^*[(\omega', (Y, \beta))] = [(\mathfrak{f}^*\omega', (X, \alpha))]$ for a representative $(f, \mathfrak{f}) : (X, \alpha) \to (Y, \beta)$ `Chapter16/FormsPullback · PolyfoldClass.ScMap.pullback Chapter16/FormsPullback · PolyfoldClass.ScMap.pullback_mk`, linearly, commuting with d, functorially. *Step 1, on a representative* `Chapter16/FormsPullback · PolyfoldClass.MapRep.pullback`: $\omega' \mapsto \mathfrak{f}^*\omega'$ through the representatives on the structures of the representative (Step 5 above), a linear map. *Step 2, independence of the representative* `Chapter16/FormsPullback · PolyfoldClass.MapRep.pullback_eq_of_equiv`, with no effectiveness: for related representatives with the square $\mathfrak{f}' \circ h = k \circ \mathfrak{f}$, the key identity is $\mathfrak{f} = k^{-1} \circ \mathfrak{f}' \circ h$, and pull-back is contravariantly functorial on the localization (Theorem 11.2.1), so $\mathfrak{f}^* = h^* \circ \mathfrak{f}'^* \circ (k^{-1})^*$; but forms on a class are identified exactly along h and k (Definition 16.2.5), whichever k the square uses. So the non-uniqueness of §XVI.4 does not reach pull-backs. *Step 3, d* `Chapter16/FormsPullback · PolyfoldClass.ScMap.d_comp_pullback`: $d \circ \widehat{f}^* = \widehat{f}^* \circ d$, because generalized maps commute with d (Theorem 11.2.1 (2), Part XI). *Step 4, functoriality.* $1^* = 1$ `Chapter16/FormsPullback · PolyfoldClass.ScMap.pullback_id`; $(\widehat{g} \circ \widehat{f})^* = \widehat{f}^* \circ \widehat{g}^*$ on representatives `Chapter16/FormsPullback · PolyfoldClass.ScMap.pullback_mk_comp`, and on classes for an effective middle polyfold, where the composite is defined `Chapter16/FormsPullback · PolyfoldClass.ScMap.pullback_comp`. With the complex this is Theorem 16.2.6 in full.

Not formalized from §16.2. Remark 16.2.7 (§XVI.28).

Where Lean departs from the text. The remark before Definition 16.2.5 cites Proposition 11.2.9; the formalization states it with (LR) on either side, since in a polyfold both ep-groupoids have (LR) and the comparison is sometimes made from the target. Definition 16.2.5 is restated: the text defines the vector space operations on classes by the formulas $[(\omega, q)] + [(\omega', q)] = [(\omega + \omega', q)]$ and $r[(\omega, q)] = [(r\omega, q)]$, which presupposes that any two classes have representatives on a common structure and that the result does not depend on it; the formalization transports the structure from one structure of c and proves the formulas for all. The pull-back half of Theorem 16.2.6 is printed with a one-line proof; the formalization isolates the one point that needs care, independence of the representative of $\widehat{f}$, and shows it uses no effectiveness.

XVI.11 Definitions 16.3.1, 16.3.3–16.3.5 and Lemma 16.3.2 (2017: Definitions 16.16–16.19), pp. 721–723: strong polyfold bundles

Statement. *Definition 16.3.1* (p. 721, same) `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure`: a strong polyfold bundle structure for a continuous surjection $p : Y \to Z$ is a strong bundle $(P : W \to X, \mu)$ over an ep-groupoid X with (ZHOU), paracompact $|X|$ and the local regularity property of Definition 8.4.2, together with homeomorphisms $\Gamma : |W| \to Y$ and $\gamma : |X| \to Z$ with $p \circ \Gamma = \gamma \circ |P|$. *Lemma 16.3.2* (p. 722, same; new in 2021) `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.lemma_16_3_2`: Y and Z are metrizable. *Definition 16.3.3* (p. 722, same) `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.Equiv`: two structures are equivalent if a generalized strong bundle isomorphism F covering a generalized isomorphism f has $\gamma' \circ |f| = \gamma$ and $\Gamma' \circ |F| = \Gamma$. *The uniqueness after Definition 16.3.3* (p. 723, does not hold as we read it; holds for an effective target base) `Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.Uniqueness_16_3_3 Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.not_uniqueness_16_3_3 Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.uniqueness_16_3_3_of_isEffective`. *The induced polyfold* (p. 723, same) `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.toPolyfoldStructure`. *Definition 16.3.4* (p. 723, same) `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundle`: a strong polyfold bundle

is p with an equivalence class $\bar{c}$ of structures. *Definition 16.3.5* (p. 723, (1) same, (2)–(3) restated) `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundle.IsTame` `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundle.IsWeaklyFaceStructured` `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundle.IsFaceStructured`: tame, weakly face-structured, face-structured.

Proof of Definition 16.3.1's consequences. *Step 1, p is determined* `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.p_eq`: $p = \gamma \circ |P| \circ \Gamma^{-1}$, and in orbit form $p(\Gamma|w|) = \gamma(|P(w)|)$ `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.p_Γ`. *Step 2* `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.continuous_p` `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.surjective_p`: p is continuous, as $|P|$ is (Part VIII), and surjective, as P is surjective on objects. The text assumes both; they follow.

Proof of Lemma 16.3.2. Z: $|X|$ is paracompact, and Theorem 7.3.1 with Chapter 2's metrization theorem make it metrizable (§XVI.1); γ is a homeomorphism. Y: Proposition 8.4.1 (Part VIII) shows that $|W|$ is paracompact and metrizable for a strong bundle over an ep-groupoid with paracompact orbit space and the local regularity property, through the metrizability of orbit spaces `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.lemma_16_3_2`; Γ is a homeomorphism.

Proof that Definition 16.3.3 is an equivalence relation. *Step 1, orbit maps of generalized strong bundle maps compose.* This is the strong bundle form of Proposition 10.3.11. On a diagram of strong bundle equivalences the orbit maps compose `Chapter16/StrongPolyfoldBundle · SBLocalization.SDiagram.orbitMap_comp'`, the proof running on the weak fibre product $W'' \times_{W'} V''$ of the middle bundles through the action μ of Chapter 10, and the identity diagram has the identity orbit map `Chapter16/StrongPolyfoldBundle · SBLocalization.SDiagram.orbitMap_id'`. So for generalized strong bundle maps `Chapter16/StrongPolyfoldBundle · SBLocalization.GenSBMap.orbitMap_comp` `Chapter16/StrongPolyfoldBundle · SBLocalization.SEPLoc.orbitMap_comp` `Chapter16/StrongPolyfoldBundle · SBLocalization.SEPLoc.orbitMap_id`, also for inverses `Chapter16/StrongPolyfoldBundle · SBLocalization.SEPLoc.orbitMap_inv_comp` `Chapter16/StrongPolyfoldBundle · SBLocalization.SEPLoc.orbitMap_comp_inv`, and for the base maps `Chapter16/StrongPolyfoldBundle · SBLocalization.GenSBMap.base_comp` `Chapter16/StrongPolyfoldBundle · SBLocalization.GenSBMap.baseOrbitMap_comp` `Chapter16/StrongPolyfoldBundle · SBLocalization.SEPLoc.baseOrbitMap_comp`. *Step 2* `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.Equiv.refl` `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.Equiv.symm` `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.Equiv.trans`: as in §XVI.1, by the identity, inverses and composites, with Step 1 for the two conditions. The quotient `Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.setoid` is the type of strong polyfold bundles for p. *Step 3, the base condition is redundant* `Chapter16/PolyfoldSections · StrongPolyfoldBundleStructure.Γ_base` `Chapter16/PolyfoldSections · StrongPolyfoldBundleStructure.equiv_iff_exists_Γ`: $\Gamma' \circ |F| = \Gamma$ implies $\gamma' \circ |f| = \gamma$, because $\gamma \circ |P| = p \circ \Gamma = p \circ \Gamma' \circ |F| = \gamma' \circ |P'| \circ |F| = \gamma' \circ |f| \circ |P|$ and $|P|$ is surjective.

Proof that the uniqueness after Definition 16.3.3 does not hold as we read it. The text says that for equivalent structures f and F are uniquely determined, by $|f| = \gamma'^{-1} \circ \gamma$, (ZHOU), Theorem 10.3.19 and Proposition 10.4.7. The claim in Lean: any two generalized strong bundle isomorphisms satisfying both conditions agree, on the bases and on the bundles. *Step 1, the example* `Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.z3Structure`: the trivial bundle $\mathbb{R} \times \mathbb{R}^k \to \mathbb{R}$ over $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$, with $\mathbb{Z}/3$ acting trivially on base and fibres, and $\Gamma = \gamma = \mathrm{id}$ after the identifications of §XVI.1. It satisfies (ZHOU), has a paracompact orbit space and the local regularity property `Chapter10/LocalizationLRCounterexample · LocalizationLRCounterexample.isLR_z3EpBundle`, so it is a strong polyfold bundle structure in the exact sense of Definition 16.3.1; its class is a strong polyfold bundle

Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.z3Bundle. *Step 2, two isomorphisms.* The generalized strong bundle isomorphisms $[1_W]$ and $[W \xleftarrow{1} W \xrightarrow{\mathrm{Inv}} W]$ of Remark 10.5.5 (Part X) induce the identity on both orbit spaces Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.z3_orbitMap_id Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.z3_baseOrbitMap_id, so both satisfy the conditions of Definition 16.3.3. *Step 3, they differ, already on the bases* Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.uniqueness_16_3_3_counterexample: the base maps are the pair of §XVI.2. The base is not effective Chapter16/PolyfoldBundleUniqueness · StrongPolyfoldBundleStructure.not_isEffective_z3Structure. This is the bundle form of §XVI.2.

Proof of the effective form. For an effective target base, f is unique by Theorem 10.3.19 for an effective target (§XVI.2), and F is then unique by Theorem 10.5.7 for an effective base (Part X), which determines a generalized strong bundle isomorphism by its orbit map and base. Nothing later in §16.3 uses the uniqueness: the relations of §§16.3, 16.5 and 16.6 are proved independent of the isomorphisms (decision (5)).

Proof of the induced polyfold and Definition 16.3.4. *Step 1* Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.toPolyfoldStructure: (X, γ) is a polyfold structure on Z, its two conditions being part of Definition 16.3.1. *Step 2* Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundleStructure.toPolyfoldStructure_equiv: equivalent bundle structures give equivalent polyfold structures, through the base f of F (Remark 10.5.3). *Step 3* Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundle.polyfold: a strong polyfold bundle has a polyfold (Z, c), the class of the bases of its structures.

Proof of Definition 16.3.5. (1) A strong polyfold bundle is tame if (Z, c) is (Definition 16.1.20), equivalently if the base of every structure is tame Chapter16/StrongPolyfoldBundle · StrongPolyfoldBundle.isTame_iff, by Lemma 16.1.19 (§XVI.5). (2), (3): through representatives Chapter16/StrongPolyfoldBundle · PolyfoldClass.IsWeaklyFaceStructured Chapter16/StrongPolyfoldBundle · PolyfoldClass.IsFaceStructured, since Definition 16.1.21 (faces of a polyfold) is not formalized. Face structure holds for one representative iff for all Chapter16/StrongPolyfoldBundle · PolyfoldClass.isFaceStructured_iff, by Remark 11.1.7 (Part XI); for weak face structure the invariance under generalized isomorphisms is not formalized, and "some representative" is the reading (§XVI.28).

Where Lean departs from the text. The text lists the continuity and surjectivity of p among the data; the formalization derives them from the structure. In Definition 16.3.3 the text imposes both $\gamma' \circ |f| = \gamma$ and $\Gamma' \circ |F| = \Gamma$; the second implies the first, which the formalization proves and then uses to state every class-level relation of §§16.3, 16.5, 16.6 through Γ alone. For the uniqueness after Definition 16.3.3, the text's argument (Theorem 10.3.19 for f, then Proposition 10.4.7 for F) is tested step by step, as in §XVI.2; the first step does not hold as we read it on the $\mathbb{Z}/3$ bundle, and the effective form uses Theorem 10.5.7 in place of the text's second step. Definition 16.3.5 (2), (3) are restated through representatives, because the faces of a polyfold (Definition 16.1.21) are not formalized.

XVI.12 Definitions 16.3.6–16.3.8 (2017: Definitions 16.20–16.22), pp. 724–726: the category $\mathcal{SPBS}$ and strong polyfold bundle maps

Statement (same). *Definition 16.3.6* (p. 724) Chapter16/PolyfoldBundleCategory · SPBS: the category $\mathcal{SPBS}$ of strong polyfold bundle structures. A morphism Chapter16/PolyfoldBundleCategory · SPBS.Hom from (W, Γ, γ) over p to (W', Γ', γ') over p' is $(A, a, \mathfrak{A}, \mathfrak{a})$ with continuous $A : Y \to Y'$, $a : Z \to Z'$, a generalized

strong bundle map $\mathfrak{A}$ covering $\mathfrak{a}$, $\Gamma' \circ |\mathfrak{A}| = A \circ \Gamma$ and $\gamma' \circ |\mathfrak{a}| = a \circ \gamma$. *Definition 16.3.7* (p. 725) `Chapter16/PolyfoldBundleCategory · SPBS.MorEquiv`: two morphisms are equivalent if they differ by invertible morphisms of the special form $(\mathfrak{H}, \mathrm{Id}_Y)$ on both sides. *Definition 16.3.8* (p. 726) `Chapter16/PolyfoldBundleCategory · SPBS.StrongPolyfoldBundleMap`: an sc-smooth strong polyfold bundle map is a class of morphisms between structures of $\bar{c}$ and $\bar{c}'$.

Proof of Definition 16.3.6. *Step 1* `Chapter16/PolyfoldBundleCategory · SPBS.Hom.p_comm`: $p' \circ A = a \circ p$ follows, since $p' \circ A \circ \Gamma = p' \circ \Gamma' \circ |\mathfrak{A}| = \gamma' \circ |P'| \circ |\mathfrak{A}| = \gamma' \circ |\mathfrak{a}| \circ |P| = a \circ \gamma \circ |P| = a \circ p \circ \Gamma$, and Γ is surjective. The text lists it as a condition. *Step 2* `Chapter16/PolyfoldBundleCategory · SPBS.Hom.id Chapter16/PolyfoldBundleCategory · SPBS.Hom.comp Chapter16/PolyfoldBundleCategory · SPBS.category`: identities and componentwise composition, with Step 1 of §XVI.11 for the orbit maps; the laws hold componentwise. A constructor from the bundle data alone `Chapter16/PolyfoldBundleCategory · SPBS.mk'` derives the base conditions. *Step 3, invertibility* `Chapter16/PolyfoldBundleCategory · SPBS.Hom.IsInvertible Chapter16/PolyfoldBundleCategory · SPBS.isIso_iff_isInvertible`: a morphism is invertible in the text's sense (A, a homeomorphisms, $\mathfrak{A}$ a generalized strong bundle isomorphism) iff it is an isomorphism of the category, the inverse being $(A^{-1}, a^{-1}, \mathfrak{A}^{-1}, \mathfrak{a}^{-1})$ `Chapter16/PolyfoldBundleCategory · SPBS.Hom.inv Chapter16/PolyfoldBundleCategory · SPBS.Hom.comp_inv Chapter16/PolyfoldBundleCategory · SPBS.Hom.inv_comp`. *Step 4, the text before Definition 16.3.7* `Chapter16/PolyfoldBundleCategory · SPBS.exists_isInvertible_iff_equiv`: $\bar{c}$ consists of the structures related to a given one by an invertible morphism $(\mathfrak{A}, \mathrm{Id}_Y)$, and for such a morphism $A = \mathrm{id}$ forces $a = \mathrm{id}$ `Chapter16/PolyfoldBundleCategory · SPBS.Hom.f_eq_id Chapter16/PolyfoldBundleCategory · SPBS.inv_F_eq_id`, by Step 1 and the surjectivity of p.

Proof of Definitions 16.3.7 and 16.3.8. *Step 1* `Chapter16/PolyfoldBundleCategory · SPBS.MorEquiv.F_eq Chapter16/PolyfoldBundleCategory · SPBS.MorEquiv.f_eq`: equivalent morphisms have $A_1 = A_0$ and $a_1 = a_0$, comparing the continuous components of the square. *Step 2* `Chapter16/PolyfoldBundleCategory · SPBS.MorEquiv.refl Chapter16/PolyfoldBundleCategory · SPBS.MorEquiv.symm Chapter16/PolyfoldBundleCategory · SPBS.MorEquiv.trans`: an equivalence relation, by the identity, inverses and pasting squares, as for Definition 16.1.6. *Step 3* `Chapter16/PolyfoldBundleCategory · SPBS.MorRep Chapter16/PolyfoldBundleCategory · SPBS.MorRep.Rel Chapter16/PolyfoldBundleCategory · SPBS.MorRep.setoid`: representatives are morphisms between structures of $\bar{c}$ and $\bar{c}'$, and the maps are the quotient. *Step 4, the continuous maps* `Chapter16/PolyfoldBundleCategory · SPBS.StrongPolyfoldBundleMap.toFun Chapter16/PolyfoldBundleCategory · SPBS.StrongPolyfoldBundleMap.baseFun Chapter16/PolyfoldBundleCategory · SPBS.StrongPolyfoldBundleMap.continuous_toFun Chapter16/PolyfoldBundleCategory · SPBS.StrongPolyfoldBundleMap.p_comm`: A and a are well defined on classes by Step 1, continuous, and commute with the projections. *Step 5* `Chapter16/PolyfoldBundleCategory · SPBS.StrongPolyfoldBundleMap.id Chapter16/PolyfoldBundleCategory · SPBS.StrongPolyfoldBundleMap.toFun_id`: the identity map. The composition of strong polyfold bundle maps on classes would meet the question of §XVI.4; the text does not define it, and it is not formalized.

Where Lean departs from the text. The text defines $\mathcal{SPBS}$, its equivalence of morphisms and the strong polyfold bundle maps without verifying the category laws or the relation; the formalization proves them, and derives the commutation $p' \circ A = a \circ p$ and the base condition $\gamma' \circ |\mathfrak{a}| = a \circ \gamma$ from the bundle conditions. The text's remark before Definition 16.3.7, that $\bar{c}$ consists of the structures related by invertible morphisms over the identity of Y, is proved as an equivalence with Definition 16.3.3. The text does not define the composition of strong polyfold bundle maps on classes; by the mechanism of §XVI.4 it would need an effective middle base, and it is not formalized.

XVI.13 Definition 16.3.9 (2017: Definition 16.23), Proposition 16.3.10, Remark 16.3.11, p. 726: auxiliary norms

Statement. *Definition 16.3.9* (restated) `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.IsAuxNorm`: a function $n : Y \to \mathbb{R}$ is an auxiliary norm for $\bar{c}$ if, for every structure of $\bar{c}$, the function $N(e) = n(\Gamma(|e|))$ on $W_{0,1}$ `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.normOf` is an auxiliary norm of W in the sense of Definition 12.2.1 `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.IsAuxNormFor`. The text says one structure suffices `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.definition_16_3_9`. *(16.7)* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.normOf_pull`: $N = [D]^* N'$ for related structures. *Proposition 16.3.10* (same) `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.proposition_16_3_10`: auxiliary norms exist. *Remark 16.3.11* (nothing to formalize): prose. *Restated* because the text's n is a function on $Y_{0,1}$, the image of the level-$(0,1)$ part; the formalization takes a function on Y whose values on $Y_{0,1}$ matter, so that no subtype of Y needs a topology.

Background: auxiliary norms on a strong bundle. Over an ep-groupoid, an auxiliary norm of a strong bundle $P : W \to X$ (Definition 12.2.1, Part XII) is a continuous function $N : W_{0,1} \to [0,\infty)$ on the bi-level $(0,1)$ part, invariant under the action of the morphisms, whose restriction to every fibre is a complete norm on the level-1 fibre, and which has the compactness property: if $P(h_k) \to x$ and $N(h_k) \to 0$, then $h_k \to 0_x$ in $W[1]$. Invariance is what lets N descend to $|W[1]|$ and hence, through Γ, to a function on $Y_{0,1}$; the compactness property is what Proposition 16.3.16 (1) reads on Y. Auxiliary norms are the device by which Chapter 12 makes sense of "small" perturbations of an sc-Fredholm section: a multisection is controlled if its pointwise norm $N(\Lambda)$ is at most 1 (§XVI.26), and properness (Definition 12.4.1) is a compactness statement for sublevel sets of $N \circ F$. The polyfold definitions of §16.3 are these notions moved to Y along the homeomorphisms Γ; the only substantive points are that the move does not depend on the structure, and that the reflexive variants of §XVI.14, whose definitions involve sequences and weak limits rather than pointwise values, move as well.

The set $Y_{0,1}$. *Step 1* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.Y01`: for a structure, $Y_{0,1} = \Gamma(|W_{0,1}|)$, with the map $|W[1]| \to Y$ `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.oneToY`. *Step 2* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.Y01_subset_of_equiv` `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.Y01_eq_of_equiv`: it does not depend on the structure, since generalized strong bundle isomorphisms preserve the bi-level $(0,1)$ (Chapter 10) and commute with Γ. So $Y_{0,1}$ is defined for the bundle `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.Y01` `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.Y01_eq`. *Step 3* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.oneToY_pull`: the maps $|W[1]| \to Y$ of related structures are compatible with the orbit map of the realizing isomorphism.

Proof of Definition 16.3.9, "one structure suffices". *Step 1, invariance of N* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.isOneInvariant_normOf`: $N = n \circ \Gamma \circ \pi$ is invariant under the morphisms of W, since π is. *Step 2, (16.7).* For related structures through F, $N = N' \circ F$ on orbits, from $\Gamma' \circ |F| = \Gamma$ `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.normOf_pull`. *Step 3* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.isAuxNormFor_of_equiv`: auxiliary norms pull back along generalized strong bundle isomorphisms, Proposition 11.5.1 (Part XI). So if N' is an auxiliary norm, so is N. *Step 4.* The definition quantifies over all structures; Step 3 gives the equivalence with one. *Continuity and nonnegativity.* The continuity of n on $Y_{0,1}$ is read in the topology of $|W[1]|$ carried by Γ, where it is the continuity of the descended function `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.normOrbit` `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.continuous_normOrbit`, and nonnegativity `Chapter16/`

PolyfoldAuxNorm · StrongPolyfoldBundle.IsAuxNorm.nonneg follows from that of N.

Proof of Proposition 16.3.10. *Step 1.* Take a structure of $\bar{c}$. Theorem 12.2.2 (Part XII) gives an auxiliary norm N of W, using the paracompactness of $|X|$, which is part of Definition 16.3.1. *Step 2, descend* Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.descend Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.normOf_descend Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundleStructure.descend_oneToY: N is invariant, so $n(\Gamma|e|) = N(e)$ defines n on $Y_{0,1}$, extended by 0, and N is recovered as $n \circ \Gamma \circ \pi$. *Step 3* Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.isAuxNorm_descend: n is an auxiliary norm by Definition 16.3.9 for one structure.

Where Lean departs from the text. The text writes $n : Y_{0,1} \to [0, \infty)$; the formalization takes $n : Y \to \mathbb{R}$, with only its values on $Y_{0,1}$ entering the definition. This avoids giving the subset $Y_{0,1}$ its own topology: continuity is read in the topology of $|W[1]|$ carried by Γ, which is the topology the text intends (the bi-level $(0, 1)$ topology). The text's reason that one structure suffices is (16.7); the formalization makes it Proposition 11.5.1 applied to a realizing isomorphism, (16.7) being the identity $N = [D]^* N'$ that the proposition uses. Proposition 16.3.10 is proved as printed, by Theorem 12.2.2 in a representative, with the paracompactness that Definition 16.3.1 now includes.

XVI.14 Definitions 16.3.12–16.3.14 (2017: Definitions 16.24–16.26), p. 727: reflexive 1-fibres, mixed convergence, reflexive auxiliary norms, and their independence of the model

Statement. *Definitions 16.3.12, 16.3.13, 16.3.14* (same) Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.HasReflexiveFibers Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.MixedTendsto Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.IsReflexiveAuxNorm: $\bar{c}$ has reflexive 1-fibres if some model of $\bar{c}$ has them (Definition 12.2.6, with compatible charts whose fibre F_1 is reflexive); $y_k \to y$ in the mixed sense if this holds in some model (Definition 12.2.8); n is a reflexive auxiliary norm if it is represented in some model by a reflexive auxiliary norm (Definition 12.2.10). Mixed convergence in a given model Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.MixedTendstoIn. *The parenthetical of Definition 16.3.12* (same) Chapter16/ReflexivePush · StrongPolyfoldBundle.hasReflexiveFibers_iff_forall: then every model has reflexive 1-fibres. *The model does not matter for mixed convergence* (same; the remark before Theorem 16.3.17) Chapter16/MixedTransfer · StrongPolyfoldBundle.mixedTendsto_iff_forall, *nor for reflexive auxiliary norms* (same) Chapter16/MixedTransfer · StrongPolyfoldBundle.isReflexiveAuxNorm_iff_forall.

Proof, the pull direction for reflexive fibres. *Step 1, charts* Chapter16/ReflexivePull · StrongBundle.LocalIso.exists_reflexive_chart. Let $\Phi : W|U \to W'|U'$ be a local strong bundle isomorphism over ϕ, and $x \in U$. A compatible chart of W' at $\phi(x)$ whose fibre F_1 is reflexive gives one of W at x: restrict the chart to U', then transport it along Φ^{-1}; the transported chart is compatible with the strong bundle structure of W because Φ is a strong bundle isomorphism, and its fibre model is the same Banach space, so it is reflexive. *Step 2, bundles* Chapter16/ReflexivePull · StrongBundle.hasReflexiveFibers_of_isStrongBundleIsoOn: if the objects of X are covered by the domains of such isomorphisms, reflexive 1-fibres of W' give reflexive 1-fibres of W. *Step 3, equivalences* Chapter16/ReflexivePull · EpStrongBundle.IsStrongBundleEquivalence.hasReflexiveFibers_of: for a strong bundle equivalence $W \to W'$ (Definition 10.4.1), the local isomorphisms covering the objects are part (2) of the definition, so reflexive 1-fibres of W' give those of W, with no hypothesis added.

Proof, the push direction for reflexive fibres Chapter16/ReflexivePush · EpStrongBundle.

IsStrongBundleEquivalence.hasReflexiveFibers_push. For a strong bundle equivalence $L : W \to W'$ over ϕ and reflexive 1-fibres of W: *Step 1.* For $x' \in X'$ pick x and a morphism $\sigma : \phi(x) \to x'$ of X', which exist because ϕ is essentially surjective. *Step 2.* L is a local strong bundle isomorphism near x; its inverse L_0^{-1} and Step 1 of the pull direction give a reflexive chart of W' at $\phi(x)$. *Step 3.* The action μ of W' along σ is a local strong bundle isomorphism from a neighbourhood of $\phi(x)$ to one of x' (Chapter 10, the morphism form of the local isomorphisms of a strong bundle); Step 1 of the pull direction for its inverse moves the reflexive chart to x'. *Step 4, along generalized isomorphisms* Chapter16/ReflexivePush · EpStrongBundle.IsStrongBundleEquivalence.hasReflexiveFibers_iff Chapter16/ReflexivePush · SBLocalization.SDiagram.hasReflexiveFibers_of Chapter16/ReflexivePush · SBLocalization.GenSBMap.hasReflexiveFibers_iff: with both directions, reflexivity passes along the two legs of a diagram. *Step 5, structures and the class* Chapter16/ReflexivePush · StrongPolyfoldBundleStructure.hasReflexiveFibers_of_equiv Chapter16/ReflexivePush · StrongPolyfoldBundle.HasReflexiveFibers.of_mem: equivalent structures have reflexive 1-fibres together, so "some model" and "every model" agree, which is the parenthetical.

Proof for mixed convergence. *Step 1, along a local strong bundle isomorphism* Chapter16/MixedTransfer · StrongBundle.LocalIso.mixedTendsto. Let Φ be a local strong bundle isomorphism into a bundle with reflexive fibres, and $w_k \to w$ in the mixed sense: the base points converge, (w_k) is bounded on level 1 in local charts, and $w_k \rightharpoonup w$ weakly. In charts, Φ is linear and bounded on the fibres, uniformly near the base point: Proposition 5.1.3 (Part V) gives the chart form, and a bound of the fibre norms of the image by a multiple of the auxiliary norm holds near the point. Bounded sequences stay bounded, and a bounded linear map preserves weak limits; the fibre seminorms compose Chapter16/MixedTransfer · StrongBundle.LocalIso.isFiberSeminorm_comp, and the property is stable under eventual equality Chapter16/MixedTransfer · StrongBundle.MixedTendsto.congr_eventually. *Step 2, along a diagram* Chapter16/MixedTransfer · SBLocalization.SDiagram.exists_mixedTendsto_transfer. For $W \xleftarrow{L} W'' \xrightarrow{L'} W'$ and $w_k \to w$ in W: move the sequence along a morphism σ into the image of L by the action, which is a local strong bundle isomorphism (with the identity $\mu(1,-)$ Chapter16/MixedTransfer · SBLocalization.mk_actOne); lift through a local inverse of L at the base point; push through L', a local isomorphism; Step 1 at each stage. The images represent the orbits of the images of w_k and converge in the mixed sense. *Step 3, structures* Chapter16/MixedTransfer · StrongPolyfoldBundleStructure.mixedTendstoIn_of_equiv: for equivalent structures, mixed convergence of $y_k \to y$ read in one gives it in the other, through a sequence patched to the representatives that Step 2 provides, compatible with the maps $|W[1]| \to Y$ Chapter16/MixedTransfer · StrongPolyfoldBundleStructure.oneToY_of_oneOrbitMap. *Step 4* Chapter16/MixedTransfer · StrongPolyfoldBundle.mixedTendsto_iff_forall: the model does not matter.

Proof for reflexive auxiliary norms. *Step 1* Chapter16/MixedTransfer · SBLocalization.SDiagram.isReflexiveAuxNorm_pullNorm Chapter16/MixedTransfer · SBLocalization.SDiagram.isReflexiveAuxNorm_pushNorm: along a diagram, a reflexive auxiliary norm pulls back and pushes forward to one. Reflexivity of a norm (Definition 12.2.10) is lower semicontinuity along mixed convergent sequences; by the mixed-convergence transfer of the previous proof, applied in both directions (the push direction through the inverse diagram), it moves with the norm. *Step 2* Chapter16/MixedTransfer · SBLocalization.GenSBMap.isReflexiveAuxNorm_pullNorm Chapter16/MixedTransfer · SBLocalization.GenSBMap.isReflexiveAuxNorm_pushNorm: for generalized strong bundle isomorphisms, through representative diagrams. *Step 3* Chapter16/MixedTransfer · StrongPolyfoldBundleStructure.isReflexiveAuxNorm_of_equiv Chapter16/MixedTransfer · StrongPolyfoldBundle.IsReflexiveAuxNorm.of_mem Chapter16/MixedTransfer · StrongPolyfoldBundle.isReflexiveAuxNorm_iff_forall: for related structures, $N = [D]^* N'$ by (16.7), so N is reflexive iff N' is, and Definition 16.3.14 does not depend on the structure.

Hypotheses. The text's standing hypothesis in Definitions 16.3.13 and 16.3.14, reflexive 1-fibres, is the context; no hypothesis is added. Gap G.166 is closed.

Where Lean departs from the text. The text asserts in a parenthesis that reflexivity of the 1-fibres does not depend on the model, and before Theorem 16.3.17 that mixed convergence does not either; no proof is given. The formalization proves both, together with the independence of reflexive auxiliary norms, which the text uses implicitly when it speaks of a reflexive auxiliary norm of $\bar{c}$. The proofs are transports along the two legs of a diagram, with one asymmetry: along the leg that is an equivalence into the target, reflexivity pulls back by transporting a chart, while in the other direction it must also be moved along the morphisms of the target, through the action μ. Mixed convergence additionally needs that a local strong bundle isomorphism is bounded and linear on the fibres, uniformly near a point, which the chart form of Proposition 5.1.3 provides.

XVI.15 Theorem 16.3.15, Proposition 16.3.16, Theorem 16.3.17 (2017: Theorems 16.3, 16.4, Proposition 16.5), pp. 727–728

Statement. *Theorem 16.3.15* (same) `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.theorem_16_3_15_one` `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.theorem_16_3_15_two`: if $\bar{c}$ has reflexive 1-fibres, (1) a reflexive auxiliary norm exists, and (2) every auxiliary norm n admits reflexive auxiliary norms $n_1 \le n \le n_2$ on $Y_{0,1}$. *Proposition 16.3.16 (1)* (stronger) `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.proposition_16_3_16_one`: if $p(y_k) \to z$ and $n(y_k) \to 0$, then $y_k \to 0_z$; the formal statement is for every auxiliary norm, with the convergence in $|W[1]|$ of a model, and does not use reflexivity. *Proposition 16.3.16 (2)* (same) `Chapter16/MixedTransfer · StrongPolyfoldBundle.proposition_16_3_16_two`: for a reflexive auxiliary norm n and $y_k \to y$ in the mixed sense, $n(y) \le \liminf n(y_k)$. *Theorem 16.3.17 (1)* (same) `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.theorem_16_3_17_one`: over a tame polyfold, an auxiliary norm of $Y_{0,1}|\partial Z$ extends to an auxiliary norm. *Theorem 16.3.17 (2)* (narrower) `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.theorem_16_3_17_two_hyp`: if the boundary norm is reflexive, the extension can be taken reflexive, with the reflexive local step of Theorem 12.2.13 as an added hypothesis.

Proof of Theorem 16.3.15. *Step 1.* By the parenthetical of Definition 16.3.12 (§XVI.14), the chosen structure of $\bar{c}$ has reflexive 1-fibres. *Step 2, (1).* Theorem 12.2.11 (Part XII) gives a reflexive auxiliary norm N of W; descend it as in Proposition 16.3.10 (§XVI.13). *Step 3, (2).* For an auxiliary norm n, its representative N on the structure is an auxiliary norm (Definition 16.3.9), and the sandwich form of Theorem 12.2.11 gives reflexive $N_1 \le N \le N_2$; they descend to $n_1 \le n \le n_2$ on $Y_{0,1}$, because the inequality is pointwise on orbits.

Proof of Proposition 16.3.16 (1). *Step 1, lift the sequence.* $p(y_k) \to z$ in Z; through the open quotient map $X \to |X| \to Z$, pick x over z and lift a tail of the sequence to objects $x_k \to x$, and w_k over x_k representing y_k (via Γ and the surjectivity of $W_{0,1} \to Y_{0,1}$ on orbits). *Step 2, align the representatives.* For each k a morphism moves the chosen representative to one over x_k; the value of the action at level 1 is the representative needed, so $N(w_k) = n(y_k) \to 0$ for N the representative of n. *Step 3, the compactness property.* Theorem 12.2.2's auxiliary norm property, which holds for every auxiliary norm (Definition 12.2.1 (2)), states that $x_k \to x$ and $N(w_k) \to 0$ imply $w_k \to 0_x$ in $W[1]$. *Step 4.* Taking orbits and Γ, $y_k \to 0_z$ in the topology of $|W[1]|$ carried by Γ. *Stronger* because the text states it for reflexive auxiliary norms and the proof does not use reflexivity.

Proof of Proposition 16.3.16 (2). *Step 1, the same-model form* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.`

`proposition_16_3_16_two_of_mem`: if the mixed convergence is read in the model in which n is represented by a reflexive auxiliary norm N, the inequality is the reflexivity of N (Definition 12.2.10): $N(w) \leq \liminf N(w_k)$ for $w_k \to w$ in the mixed sense, read on representatives and transported by Γ. *Step 2, the text's form.* The mixed convergence may be given in any model, and n reflexive in any model; by §XVI.14 both notions are independent of the model, so the mixed convergence holds in the model where n is reflexive, and Step 1 applies.

Proof of Theorem 16.3.17 (1). *Step 1, the boundary norm* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.IsAuxNormBoundary`: an auxiliary norm of $Y_{0,1}|\partial Z$ is read as in Definition 16.3.9 over ∂X, in all models. The set $p^{-1}(\partial Z)$ corresponds to $W|\partial X$: $p(\Gamma|e|) \in \partial Z$ iff $P(e) \in \partial X$ `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.mem_boundary_iff`, by the computation of ∂Z in a representative (§XVI.5) and $p \circ \Gamma = \gamma \circ |P|$. *Step 2.* Over a tame base, Theorem 12.2.7 (Part XII) extends an auxiliary norm of $W|\partial X$ to one of W; apply it in the chosen structure, whose base is tame by Definition 16.3.5 (1). *Step 3.* Descend the extension (§XVI.13); it agrees with n over ∂Z because the representative of n over ∂X was extended.

Proof of Theorem 16.3.17 (2). *Step 1, the reading.* "n reflexive over ∂Z" is read as reflexive 1-fibres and a reflexive representative over ∂X in one model. *Step 2.* Theorem 12.2.13 (Part XII), in the form that takes its reflexive local step as a hypothesis `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.theorem_16_3_17_two_hyp`, gives a reflexive extension in that model, which descends. *The added hypothesis*, not derived from the text: the reflexive local step, that near every boundary point a reflexive auxiliary norm over the boundary has a reflexive local extension. *Witness* `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.theorem_16_3_17_two_hyp_witness`: on every bundle with reflexive 1-fibres, for the boundary norm that is the restriction of a global reflexive auxiliary norm. **This witness covers only a degenerate case**: when n is already the restriction of a global reflexive norm, the local step is satisfied by restricting that norm, and nothing is extended. The non-degenerate case is supplied by Part XII, which proves the reflexive local step over tame bases `Chapter12/ReflexiveLocalExtension · EpStrongBundle.hasReflexiveLocalExtensions_of_isTame`; Theorem 16.3.17 assumes a tame base, so the unconditional form is a one-line corollary, not stated as a separate Lean declaration. Tameness is not otherwise used.

Where Lean departs from the text. The text proves Theorem 16.3.15, Proposition 16.3.16 and Theorem 16.3.17 by the corresponding statements of Chapter 12 in a representative, and the formalization follows this. Three differences. Proposition 16.3.16 (1) is proved for every auxiliary norm, since the Chapter 12 property it rests on holds for all of them. Proposition 16.3.16 (2) needs the independence of the model of §XVI.14, which the text takes for granted, to bring the mixed convergence into the model where n is reflexive. Theorem 16.3.17 (2) takes the reflexive local step of Theorem 12.2.13 as a hypothesis, discharged over tame bases by Part XII; since Theorem 16.3.17 is stated over tame polyfolds, the text's statement holds, but the composite is not packaged as one declaration.

XVI.16 Definitions 16.3.18, 16.3.19 (2017: Definitions 16.27, 16.28), pp. 728–729: sections, the zero of a fibre and the zero section

Statement. *The relation before Definition 16.3.18* (same) `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.Rel`: a representative is (f, Γ, W, F) with f a continuous section of p and F an sc-smooth section functor of a structure with $\Gamma \circ |F| = f \circ \gamma$; two are related if $f = f'$ and a generalized strong bundle isomorphism $\mathfrak{A}$ has $\Gamma' \circ |\mathfrak{A}| = \Gamma$ and $\mathfrak{A}_* F = F'$. *Definition 16.3.18* (same) `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScSection`: an sc-smooth section

is a class. *Definition 16.3.19* (restated) `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScSection.IsScPlus` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScPlusSection`: an sc⁺-section is an sc-smooth section whose functor in one, equivalently every, representative is sc⁺. *The zero of a fibre* (p. 728, same) `Chapter16/FibreZero · StrongPolyfoldBundle.zeroAt`: $0_z = \Gamma(|0_x|)$ for $\gamma(|x|) = z$. *The zero section* (p. 728, same) `Chapter16/ZeroSection · StrongPolyfoldBundle.zeroSection`: $z \mapsto 0_z$ is an sc⁺-section.

Proof that the relation is an equivalence relation and depends only on f. *Step 1* `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.Rel.refl` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.Rel.symm` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.Rel.trans` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.setoid`: by the identity, the inverse with $(\mathfrak{A}^{-1})_* = (\mathfrak{A}_*)^{-1}$, and composites with $(\mathfrak{B} \circ \mathfrak{A})_* = \mathfrak{B}_* \circ \mathfrak{A}_*$ (Chapter 10). The text states "this defines an equivalence relation". *Step 2, the push-forward condition is redundant* `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.pushforward_eq_of_Γ`. If $\Gamma' \circ |\mathfrak{A}| = \Gamma$ and $f = f'$, then $\mathfrak{A}_* F$ and F' are section functors of W' with the same orbit map $\Gamma'^{-1} \circ f \circ \gamma$; a section functor is determined by its values on orbits. Indeed, if $F_1(x)$ and $F_2(x)$ lie in one orbit of W, a morphism of W joins them, lying over an isotropy element $g \in G_x$; then $F_2(x) = \mu(g, F_1(x))$, and $\mu(g, F_1(x)) = F_1(x)$ because F_1 is a functor, so $F_1(x) = F_2(x)$. The orbit of $(\mathfrak{A}_* F)(x)$ is computed from $|\mathfrak{A}|$ and $|F|$, which gives the equality of orbits. *Step 3* `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.rel_iff` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.SectionRep.rel_of_f_eq`: two representatives are related iff $f = f'$ and their structures are equivalent. So the non-uniqueness of §XVI.11 does not reach sections.

Proof of Definitions 16.3.18 and 16.3.19. *Step 1* `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScSection.toFun` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScSection.p_toFun` `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScSection.continuous_toFun`: the section f of a class is well defined, continuous, and a section of p. *Step 2* `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScSection.ext_toFun`: by Step 3 above, a section is determined by f (two classes with the same f have representatives with equivalent structures, hence related). *Step 3, sc⁺* `Chapter16/PolyfoldSections · StrongPolyfoldBundle.ScSection.isScPlus_iff`: being sc⁺ is invariant under push-forward by generalized strong bundle isomorphisms, Theorem 10.5.4 (Part X), so one representative is sc⁺ iff every one is. *Restated* because the text phrases Definition 16.3.19 through the continuity of f into $Y_{0,1}$; in a representative that is the continuity of F into $W_{0,1}$, which is what sc⁺ asks.

Proof of the zero of a fibre. *Step 1* `Chapter16/FibreZero · StrongPolyfoldBundleStructure.zeroAt` `Chapter16/FibreZero · StrongPolyfoldBundleStructure.zeroAt_eq`: for a structure, $0_z = \Gamma(|0_x|)$ for any x with $\gamma(|x|) = z$; it does not depend on x, because a morphism $x \to x'$ acts linearly on fibres and sends 0_x to $0_{x'}$ `Chapter16/FibreZero · SBLocalization.π_fiberZero_eq_of_π_eq`, and the action of a morphism moves a non-zero vector to a non-zero vector `Chapter16/FibreZero · SBLocalization.μ_ne_fiberZero`, so the orbits of zeros are exactly the zeros of orbits `Chapter16/FibreZero · SBLocalization.π_eq_fiberZero_iff`. *Step 2* `Chapter16/FibreZero · StrongPolyfoldBundleStructure.p_zeroAt` `Chapter16/FibreZero · StrongPolyfoldBundle.p_zeroAt`: $p(0_z) = z$. *Step 3, independence of the structure* `Chapter16/FibreZero · StrongPolyfoldBundleStructure.zeroAt_eq_of_equiv`: diagrams and generalized strong bundle maps send orbits of zeros to orbits of zeros `Chapter16/FibreZero · SBLocalization.SDiagram.orbitMap_π_fiberZero` `Chapter16/FibreZero · SBLocalization.GenSBMap.orbitMap_π_fiberZero`, since each leg is linear on fibres. *Step 4* `Chapter16/FibreZero · StrongPolyfoldBundleStructure.Γ_π_eq_zeroAt_iff`: $\Gamma(|w|) = 0_z$ iff w is the zero of its fibre and lies over z. *Auxiliary norms extended by 0* `Chapter16/FibreZero · StrongPolyfoldBundle.normY`: off $Y_{0,1}$ an auxiliary norm is set to 0, and $n(\Gamma|w|) = N(w)$ for $w \in W_{0,1}$ `Chapter16/FibreZero · StrongPolyfoldBundle.normY_Γ`; this is the reading of $n(f(z))$ in Definition 16.6.3 (§XVI.24).

Proof of the zero section. *Step 1, continuity* Chapter16/ZeroSection · StrongPolyfoldBundle.continuous_fiberZero_W Chapter16/ZeroSection · StrongPolyfoldBundle.continuous_zeroAt: the zero section functor of a model is continuous; $z \mapsto 0_z$ is continuous because $x \mapsto \Gamma(|0_x|)$ is, and $x \mapsto \gamma(|x|)$ is a quotient map Chapter16/NormLamContinuous · StrongPolyfoldBundle.isQuotientMap_γπ (§XVI.21). *Step 2, a representative in every model* Chapter16/ZeroSection · StrongPolyfoldBundle.zeroRepOf: the zero functor of a structure, which is an sc-smooth (indeed sc$^+$) section functor, with $\Gamma \circ |0| = 0_{(\cdot)} \circ \gamma$ by Step 1 of the zero of a fibre. *Step 3, the class* Chapter16/ZeroSection · StrongPolyfoldBundle.zeroSection Chapter16/ZeroSection · StrongPolyfoldBundle.zeroSection_eq_mk: all these representatives have the same map f, so they give one class (Step 3 of the relation). Its map is $z \mapsto 0_z$ Chapter16/ZeroSection · StrongPolyfoldBundle.toFun_zeroSection. *Step 4* Chapter16/ZeroSection · StrongPolyfoldBundle.isScPlus_zeroSection Chapter16/ZeroSection · StrongPolyfoldBundle.zeroPlusSection: it is an sc$^+$-section, since the zero functor is sc$^+$. *Step 5* Chapter16/ZeroSection · StrongPolyfoldBundle.rep_F_eq_fiberZero Chapter16/ZeroSection · StrongPolyfoldBundle.ScSection.eq_zeroSection_iff Chapter16/ZeroSection · StrongPolyfoldBundle.ScSection.eq_zeroSection_iff_F: a section is the zero section iff $f(z) = 0_z$ for all z, iff its functor is the zero functor in some, equivalently every, representative. *Step 6* Chapter16/ZeroSection · StrongPolyfoldBundle.solutionSet_zeroSection: the solution set of the zero section is Z. Gap G.167 is closed, and Definitions 16.3.18 and 16.3.19 have a witness on every strong polyfold bundle.

Where Lean departs from the text. The text states the relation on representatives of sections and calls it an equivalence relation; the formalization proves this and the stronger fact that the push-forward condition is implied by the others, so that a section is determined by its map f. This is what protects §§16.3–16.6 from the non-uniqueness of §XVI.11: whichever isomorphism realizes an equivalence of structures, it pushes a representative to the unique representative with the same map. The zero of a fibre is defined in the text by a representative; the formalization proves its independence of the representative and of the structure. The zero section is mentioned in the text as an example; the formalization builds it as an element of Definition 16.3.18, with representatives in every model, and characterizes it.

XVI.17 Definitions 16.4.1 and 16.4.2 (2017: Definitions 16.29, 16.30), pp. 729–730: branched suborbifolds and their properties

Statement. *Definition 16.4.1* (restated) Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold: a branched suborbifold of (Z, c) is a class $\theta = [\Theta, (X, \alpha)]$ of representatives $(\Theta, (X, \alpha))$ with $(X, \alpha) \in c$ and Θ a branched ep$^+$-subgroupoid of X Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep, where $(\Theta, (X, \alpha)) \sim (\Theta', (X', \alpha'))$ if a generalized isomorphism $f : X \to X'$ has $\alpha' \circ |f| = \alpha$ and $f^*\Theta' = \Theta$ Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep.Rel. The function $\theta = |\Theta| \circ \alpha^{-1} : Z \to \mathbb{Q}^+$ is well defined Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.toFun Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.definition_16_4_1_wellDefined. *Definition 16.4.2* (p. 730; (1)–(4) same, (5) same) Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.IsClosed Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.IsCompact Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.IsManifoldType Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.IsOrbifoldType Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.IsTame: θ is closed, compact, of manifold type, of orbifold type, or tame, if a representative Θ is; then every representative is Chapter16/BranchedTame · PolyfoldClass.BranchedSuborbifold.definition_16_4_2_tame. *Restated* for Definition 16.4.1 because the text's class notation is made into explicit pairs and the relation is proved to be an equivalence relation.

Background: branched ep⁺-subgroupoids. A branched ep⁺-subgroupoid of X (Definition 9.1.1, Part IX) is a functor $\Theta : X \to \mathbb{Q}^+$, with values in the nonnegative rationals and supported in X_∞, that near every point of its support is described by a local branching structure: finitely many finite-dimensional submanifolds $M_1, \dots, M_k$ of an open set U invariant under the natural representation, with positive rational weights $\sigma_1, \dots, \sigma_k$, such that $\Theta(y) = \sum_{i : y \in M_i} \sigma_i$ on U. It is of manifold type or of orbifold type when its support carries the corresponding structure of Proposition 9.1.9, and tame if the local branching structures can be chosen tame in the sense of Definition 9.3.6. An orientation $\widehat{T}_\Theta$ (Chapter 11) is a choice of orientations of the tangent spaces of the branches, compatible with the weights. Pull-backs along functors are composition, and push-forwards along equivalences are read on orbits; Chapter 11 extends both to generalized isomorphisms, which is the operation f^* of Definition 16.4.1. So a branched suborbifold of a polyfold is a rational-weighted, locally finitely branched, finite-dimensional subset of Z, presented in one structure and moved to any other by f^*.

Pull-backs of branched ep⁺-subgroupoids. *Step 1* `Chapter16/BranchedSuborbifold · EPLocalization.EPLoc.pullTheta_eq_of_orbitMap`: for a generalized isomorphism f and a functorial Θ', $(f^*\Theta')(x) = \Theta'(y)$ whenever $|f|(|x|) = |y|$. This is the text's $|f^*\Theta'| = |\Theta'| \circ |f|$ (p. 730). The proof goes through a representative diagram $X \xleftarrow{F} A \xrightarrow{\Phi} X'$: $f^*\Theta'$ is the push-forward along F of $\Phi^*\Theta'$, the pull-back along a functor is composition, and the push-forward along an equivalence of a functorial function is read on orbits. *Step 2* `Chapter16/BranchedSuborbifold · EPLocalization.EPLoc.pull_congr`: two generalized isomorphisms with the same orbit map pull back alike, by Step 1. *Step 3* `Chapter16/BranchedSuborbifold · EPLocalization.EPLoc.pullTheta_id_of_isFunctorial`: $1^*\Theta = \Theta$ for functorial Θ.

Proof of Definition 16.4.1. *Step 1, an equivalence relation.* Reflexive by Step 3 above `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep.Rel.refl`. Symmetric `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep.Rel.symm`: if $f^*\Theta' = \Theta$, then $(f^{-1})^*\Theta = \Theta'$, by Step 1 on orbits, since $|f^{-1}| = |f|^{-1}$. Transitive `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep.Rel.trans`: $(g \circ f)^* = f^* \circ g^*$ on functorial functions, again by Step 1. The quotient is the type of branched suborbifolds. *Step 2, the function on a representative* `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep.toFun` `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep.toFun_eq`: $z \mapsto \Theta(x)$ for any x with $\alpha(|x|) = z$, well defined because Θ is functorial. *Step 3, related representatives give the same function* `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedRep.toFun_eq_of_rel`: for $z = \alpha(|x|) = \alpha'(|y|)$ with $|y| = |f|(|x|)$, $\Theta(x) = (f^*\Theta')(x) = \Theta'(y)$ by Step 1 of the pull-backs. So θ is defined on classes, with $\theta(\alpha(|x|)) = \Theta(x)$ for every representative and every x (the well-definedness statement), and $\theta \geq 0$ `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.toFun_nonneg`. *Step 4, θ determines the class* `Chapter16/PerturbedSuborbifold · PolyfoldClass.BranchedRep.rel_of_toFun_eq` `Chapter16/PerturbedSuborbifold · PolyfoldClass.BranchedSuborbifold.toFun_injective` `Chapter16/PerturbedSuborbifold · PolyfoldClass.BranchedSuborbifold.toFun_mk`: if two representatives have the same function, any generalized isomorphism f with $\alpha' \circ |f| = \alpha$ (which exists, both structures being in c) has $f^*\Theta' = \Theta$, because both sides are read on orbits and the orbit values agree. So the non-uniqueness of §XVI.2 does not reach branched suborbifolds: the relation is "the functions agree".

Proof of Definition 16.4.2 (1)–(4) and the dimension. *Step 1, the pattern* `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.HasRepProperty` `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.hasRepProperty_iff`: a property holds for θ if it holds for some representative; for a property stable under pull-backs by generalized isomorphisms, some representative has it iff all have it, since any two representatives are related by a generalized isomorphism. *Step 2.* Closed, compact, of manifold type and of orbifold type are stable, by Theorem 11.3.3 (3)–(5)

(Part XI), so they hold for every representative iff for one Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.definition_16_4_2_closed Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.definition_16_4_2_compact Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.definition_16_4_2_manifold Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.definition_16_4_2_orbifold. *Step 3.* So is the dimension n Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.IsNDimensional Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.definition_16_4_2_nDim, by Theorem 11.3.3 (6); it is used in Theorem 16.4.6.

Proof of Definition 16.4.2 (5), tameness. The text says on p. 729 that tameness of branched ep$^+$-subgroupoids is preserved by f_* and f^*. *Step 1, restriction* Chapter16/BranchedTame · EpGroupoid.TameBranchingStructure.restrictRep: a tame local branching structure of Definition 9.3.6 at x restricts to any smaller natural representation at x. *Step 2, moving* Chapter16/BranchedTame · EpGroupoid.TameBranchingStructure.move Chapter16/BranchedTame · EpGroupoid.TameBranchingStructure.mapU_eq: it moves along an sc-diffeomorphism of open sets $W \to W'$ that intertwines the natural representations, the branches and the tame sets being carried with it, since tameness of a set (Part IV) is invariant under sc-diffeomorphisms. *Step 3, pull-back along an equivalence* Chapter16/BranchedTame · EpFunctor.isTameBranched_pullbackTheta. For an equivalence $\Phi : X \to X'$, $x \in X$ and a tame Θ': take a transport chart of Theorem 11.4.1 at x (Part XI), which identifies natural representations at x and $\Phi(x)$ through local sc-diffeomorphisms; take a tame branching structure D of Θ' at $\Phi(x)$ and a natural representation R_0 at x with the properness property (Theorem 7.1.13, Part VII); push R_0 to a representation R' inside D's domain; restrict D to R' (Step 1) and move it back along the chart (Step 2). The branches of $\Phi^*\Theta'$ near x are the pulled-back branches, so the moved structure is a tame branching structure of $\Phi^*\Theta'$. *Step 4, push-forward* Chapter16/BranchedTame · EpFunctor.isTameBranched_pushforwardTheta Chapter16/BranchedTame · EpFunctor.isTameBranched_pullbackTheta_iff: the same argument in the other direction, using that $\Phi_*\Phi^*\Theta' = \Theta'$ for functorial Θ'; so $\Phi^*\Theta'$ is tame iff Θ' is. *Step 5, generalized isomorphisms* Chapter16/BranchedTame · EPLocalization.EPLoc.isTameBranched_pullTheta: through the two legs of a diagram. *Step 6* Chapter16/BranchedTame · PolyfoldClass.BranchedSuborbifold.definition_16_4_2_tame: tameness is stable, so Step 1 of the pattern applies. Gap G.154 is closed.

Where Lean departs from the text. The text writes $|f^*\Theta'| = |\Theta'| \circ |f|$ and draws from it the well-definedness of θ; the formalization proves the identity through a representative diagram and draws, besides well-definedness, the converse: the function θ determines the class. For Definition 16.4.2 the text states that the properties hold for one representative iff for all, citing Theorem 11.3.3 for (1)–(4) and the remark on p. 729 for tameness. For (1)–(4) the formalization follows the text. For tameness the remark on p. 729 is stated without proof; the formalization proves it through the transport charts of Theorem 11.4.1, with the restriction and the moving of tame branching structures as the two lemmas that the text's remark presupposes.

XVI.18 Proposition 16.4.3 (2017: Proposition 16.4), p. 730: the structure on $\operatorname{supp}\theta$

Statement (same). For a branched suborbifold θ of manifold type (orbifold type), $\operatorname{supp}\theta = \{z : \theta(z) > 0\}$ Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.supp carries a natural manifold (orbifold) structure. In Lean, in three parts. *The set and the topology* Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_supp Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_homeomorph: for every representa-

tive, $\operatorname{supp}\theta = \alpha(|\operatorname{supp}\Theta|)$, and α restricts to a homeomorphism $|\operatorname{supp}\Theta| \cong \operatorname{supp}\theta$. *The structure on one representative* `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_manifold` `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_orbifold`: Proposition 9.1.9 (1), (2) on $|\operatorname{supp}\Theta|$. *Naturality* `Chapter16/SuppNaturality · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_naturality`: for any two representatives, and any structures induced by Proposition 9.1.9 (1) on their supports, the transition $|\operatorname{supp}\Theta| \to |\operatorname{supp}\Theta'|$ over $\operatorname{supp}\theta$ is an sc-diffeomorphism `Chapter16/SuppNaturality · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_naturality_all`. The word "natural" of the text is read as this independence of the representative, the statement being `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_naturality_statement`. The formal form is stronger than needed in one respect: the induced structures need not be chosen, since any two give the same comparison.

Proof of the set and the topology. *Step 1.* $\theta(\alpha(|x|)) = \Theta(x)$ (§XVI.17), so $\theta(z) > 0$ iff $\Theta(x) > 0$ for one, equivalently every, x over z; that is $z \in \alpha(|\operatorname{supp}\Theta|)$. *Step 2.* α is a homeomorphism $|X| \to Z$, and $|\operatorname{supp}\Theta|$ carries the subspace topology of $|X|$; so α restricts to a homeomorphism onto $\operatorname{supp}\theta$ with its subspace topology `Chapter16/BranchedSuborbifold · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_homeomorph_apply`.

Proof of the structure on one representative. *Manifold type.* With Proposition 9.1.9 (1) (Part IX), $|\operatorname{supp}\Theta|$ carries an M-polyfold structure, finite-dimensional, for which $\operatorname{supp}\Theta \to |\operatorname{supp}\Theta|$, $a \mapsto |a|$, is a local sc-diffeomorphism; it is carried to $\operatorname{supp}\theta$ by the homeomorphism above. *Orbifold type.* With Proposition 9.1.9 (2), $|\operatorname{supp}\Theta|$ is the orbit space of the ep-groupoid that X induces on $\operatorname{supp}\Theta$.

Proof of naturality. *Step 1, the transition* `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.suppTransition` `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.β_suppTransition` `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.suppTransition_eq_iff`: for two representatives Θ, Θ' of θ, the homeomorphism $t = \alpha'^{-1} \circ \alpha$ restricted to $|\operatorname{supp}\Theta| \to |\operatorname{supp}\Theta'|$, characterized by $\alpha' \circ t = \alpha$. *Step 2, the cocycle identities* `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.suppTransition_self` `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.suppTransition_trans` `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.suppTransition_symm`: $t_{aa} = 1$, $t_{a'a''} \circ t_{aa'} = t_{aa''}$, $t_{a'a} = t_{aa'}^{-1}$. *Step 3, the induced structures* `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.IsInducedSuppStructure`: a structure on $|\operatorname{supp}\Theta|$ is induced if $a \mapsto |a|$ is a local sc-diffeomorphism from $\operatorname{supp}\Theta$ with its M-polyfold structure (Proposition 9.1.9 (1)). For one representative the transition is the identity, an sc-diffeomorphism between any two induced structures `Chapter16/SuppNaturalityStatement · PolyfoldClass.BranchedSuborbifold.proposition_16_4_3_naturality_self`. *Step 4, the transition through a diagram* `Chapter16/SuppNaturality · PolyfoldClass.BranchedSuborbifold.suppTransition_orbitSuppProj`. For a generalized isomorphism $X \xleftarrow{F} A \xrightarrow{\Phi} X'$ between the representatives ($\alpha' \circ |f| = \alpha$, $f^*\Theta' = \Theta$), the transition sends $|F(b)|$ to $|\Phi(b)|$ for every b in the support of $\Phi^*\Theta'$. *Step 5, sc-smoothness* `Chapter16/SuppNaturality · PolyfoldClass.BranchedSuborbifold.isScSmoothOn_suppTransition`. The legs F and Φ restrict to equivalences of the sub-ep-groupoids on the supports (the argument of Proposition 11.1.6, Part XI), which are local sc-diffeomorphisms of the finite-dimensional M-polyfolds supp. Near $|F(b)|$, the transition is the composite $p' \circ \Phi|_{\text{supp}} \circ (F|_{\text{supp}})^{-1} \circ p^{-1}$, with p, p' the local sc-diffeomorphisms $a \mapsto |a|$ of the induced structures and $(F|_{\text{supp}})^{-1}$ a local inverse; so it is sc-smooth. Only Θ' of orbifold type is used, for the sub-ep-groupoid on the support of $\Phi^*\Theta'$; manifold type, the text's case, gives orbifold type. *Step 6, inverse.* By the cocycle identities the inverse is the transition in the other direction, sc-smooth by Step 5. Gap G.155 is closed.

Where Lean departs from the text. The text's proof of Proposition 16.4.3 is the reference to Proposition 9.1.9,

which gives the structure on $|\operatorname{supp}\Theta|$ for one representative; that the structure is natural, that is, independent of the representative, is in the word "natural". The formalization proves the independence explicitly through the transition maps between supports, and in a form stronger than a choice: any structures induced by Proposition 9.1.9 on the two supports are related by an sc-diffeomorphism. The proof needs the restriction of an equivalence to the sub-ep-groupoids on the supports, which is the argument of Proposition 11.1.6 in Part XI.

XVI.19 Definitions 16.4.4 and 16.4.5 (2017: Definitions 16.31, 16.34), pp. 730–732: oriented branched suborbifolds and their integrals

Statement. *Definition 16.4.4* (restated) `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedSuborbifold`: an oriented branched suborbifold is a class $\hat\theta = [(\Theta,\hat T_\Theta),(X,\alpha)]$ of representatives with $(\Theta,\hat T_\Theta)$ an oriented branched ep$^+$-subgroupoid of X (Chapter 11) `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep`, related by $f^*(\Theta',\hat T_{\Theta'}) = (\Theta,\hat T_\Theta)$ and $\alpha'\circ|f| = \alpha$ `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.Rel`, with an underlying branched suborbifold `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedSuborbifold.toBranched`. *Definition 16.4.5* (p. 731, same) `Chapter16/BranchedSuborbifold · PolyfoldClass.definition_16_4_5_wellDefined`: $\partial\hat\theta = [\partial(\Theta,\hat T_\Theta),(X,\alpha)]$ does not depend on the representative. *The integrals* (p. 732, same) `Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.integral` `Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.integralEff`: $\int_{\hat\theta}\tau = \mu_\omega^{\hat\Theta}(|\operatorname{supp}\Theta|)$ and $\oint_{\hat\theta}\tau$, for a tame compact oriented class, equal to the integrals on every representative `Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.integral_eq` `Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.integralEff_eq`.

Proof of Definition 16.4.4. *Step 1, the normalization.* The text's $\hat T_\Theta$ lives over X_∞, and f^* only reads it there; the formalization makes $\hat T_\Theta$ zero off X_∞ `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.mem_grHatSections`. Reflexivity needs it: $1^*\hat T = \hat T$ holds for such $\hat T$ `Chapter16/BranchedSuborbifold · EPLocalization.EPLoc.pullSection_id_of_mem` `Chapter16/BranchedSuborbifold · EPLocalization.EPLoc.pull_id_of_mem`, and fails otherwise, since the pull-back is 0 off X_∞. Every pull-back of Chapter 11 has this property, so it is a normalization, not an added hypothesis. *Step 2, an equivalence relation* `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.Rel.refl` `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.Rel.symm` `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.Rel.trans`: as in §XVI.17, with the pull-back of oriented branched ep$^+$-subgroupoids of Chapter 11 (Part XI), which is functorial on generalized isomorphisms. *Step 3* `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.toBranchedRep` `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.Rel.toBranchedRep`: forgetting the orientation respects the relations, which defines the underlying θ `Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.toBranched_mk`.

Proof of Definition 16.4.5. *Step 1.* If two representatives are related through f, then $f^*\partial\Theta' = \partial\Theta$ and $f^*\hat T_{\partial\Theta'} = \hat T_{\partial\Theta}$, by Theorem 11.3.9 (Part XI) `Chapter11/BoundaryOrientationEquiv · theorem_11_3_9_pull_boundaryOrientation`. So $\partial\hat\theta$ does not depend on the representative. *Step 2* `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryFun` `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryFun_eq_of_rel`: the boundary function $\partial\theta = |\partial\Theta|\circ\alpha^{-1}$ does not either, so neither does $\partial S = \operatorname{supp}\partial\theta$. *Readings.* The compatibility holds without tameness, which the text assumes for $\partial\hat\theta$ to be a branched suborbifold. $\partial(\Theta,\hat T_\Theta)$ is formalized componentwise, as in Chapter 11.

Proof of the integrals. *Step 1, on a representative.* A representative is tame of dimension n in the sense of Chapter 9 if oriented tame structures describe $\hat T_\Theta$ at every point of $\operatorname{supp}\Theta$ `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.IsTameOriented`. For such a representative that

is compact, $\int = \mu_\omega^{\hat\Theta}(|\operatorname{supp}\Theta|)$ Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.integral and $\oint = \mu_\omega^{\hat\Theta,\mathrm{eff}}(|\operatorname{supp}\Theta|)$ Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.integralEff, with ω the representative of τ on (X,α) (§XVI.10). For the effective integral, (ZHOU) gives the local uniqueness condition (LUC) by Proposition 7.4.10 (Part VII). *Step 2, the boundary integrals on a representative* Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryIntegral Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryIntegralEff: the measures of Theorems 9.5.15 and 9.5.16 (Part IX), with separate forms in dimension 1, where the boundary is 0-dimensional Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryIntegralDim1 Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryIntegralEffDim1. *Step 3, independence of the representative* Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.integral_eq_of_rel Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.integralEff_eq_of_rel: if two tame compact representatives are related through f, the representative of τ on the first structure is f^* of that on the second Chapter16/BranchedSuborbifold · PolyfoldClass.ScForm.toStructure_eq_formsPullback, and the tame integrals are invariant under pull-back, Theorems 11.4.1 and 11.4.2 with $K = |\operatorname{supp}\Theta|$ (Part XI) Chapter16/BranchedSuborbifold · EPLocalization.EPLoc.tameBranchedIntegral_pull Chapter16/BranchedSuborbifold · EPLocalization.EPLoc.tameBranchedIntegralEff_pull. *Step 4, tameness on classes.* Related oriented representatives are tame together Chapter16/BranchedTame · PolyfoldClass.OrientedRep.Rel.isTameOriented Chapter16/BranchedTame · PolyfoldClass.OrientedRep.Rel.isTameOriented_iff: the oriented tame structures move along the transport charts as in §XVI.17, with the orientations pulled back. So tameness of an oriented class Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.IsTameOriented holds in every representative Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.isTameOriented_iff, and compactness is that of any representative Chapter16/BranchedTame · PolyfoldClass.OrientedSuborbifold.isCompactBranched_of_mk. *Step 5, on classes.* The integral of the class is computed on the chosen representative, and by Steps 3–4 equals the integral on every representative. *Step 6, the boundary integrals.* Their independence of the representative is obtained from Stokes' theorem (§XVI.20) Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryIntegral_eq_of_rel Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryIntegralEff_eq_of_rel Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.boundaryIntegralDim1_eq_of_rel: both sides equal the integral of $d\tau$, which is independent by Step 3. This needs the hypothesis of §XVI.20, sc-smooth partitions of unity. The boundary integrals are not wrapped as functions on classes (§XVI.28); they would follow from Step 6 as the interior integrals follow from Step 3.

Where Lean departs from the text. The text defines the integrals on p. 732 through a representative and says that they do not depend on the choice; for the interior integrals the formalization proves this through Theorems 11.4.1 and 11.4.2, as the text intends. For the boundary integrals the direct route would be the boundary form of Theorem 11.4.1, which is not formalized; the formalization instead derives their independence from Stokes' theorem, which costs the hypothesis of sc-smooth partitions of unity. Definition 16.4.4 adds the normalization of $\hat T_\Theta$ off X_∞, which the text does not need to state because it only ever reads $\hat T_\Theta$ on X_∞, but which a formal reflexivity proof does need.

XVI.20 Theorem 16.4.6 (2017: Theorem 16.5), p. 732: Stokes' theorem on polyfolds

Statement (with an added hypothesis) Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.theorem_16_4_6_hyp. Let (Z,c) admit sc-smooth partitions of unity (Definition 16.1.5), $\hat\theta = [(\Theta,\hat T_\Theta),(X,\alpha)]$ oriented, compact and tame of dimension $n = m+1 \geq 2$, and $\tau \in \Omega^m_{sc}(Z,c)$. Then

$\int_{\hat\theta} d\tau = \int_{\partial\hat\theta} \tau$. The effective form Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.theorem_16_4_6_eff_hyp: $\oint_{\hat\theta} d\tau = \oint_{\partial\hat\theta} \tau$. Dimension 1 Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.theorem_16_4_6_dim1_hyp Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.theorem_16_4_6_eff_dim1_hyp. Both identities together Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.theorem_16_4_6_both_hyp.

Proof. *Step 1, to the representative.* The representative of $d\tau$ on (X,α) is d of the representative ω of τ Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.toStructure_d (§XVI.10, the formula $d[(\omega,(X,\alpha))] = [(d\omega,(X,\alpha))]$). So both sides are integrals over Θ on X: $\mu^{\tilde\Theta}_{d\omega}(|\operatorname{supp}\Theta|)$ and the boundary measure of ω. *Step 2, partitions of unity on X.* By Definition 16.1.5 (2) Chapter16/PolyfoldPartitions · PolyfoldClass.definition_16_1_5_two (§XVI.3), X admits sc-smooth partitions of unity, since (Z,c) does. *Step 3, Stokes on X.* Theorem 9.5.17 (Part IX) Chapter9/StokesTextHypotheses · theorem_9_5_17 gives the identity on X; for the effective form, Theorem 9.5.18 Chapter9/StokesTextHypotheses · theorem_9_5_18, with (LUC) from (ZHOU). In dimension 1, the dimension-1 forms of both theorems. *Step 4.* By §XVI.19, Steps 3 and 6, the result does not depend on the representative.

The added hypothesis. Theorem 16.4.6 does not state that (Z,c) admits sc-smooth partitions of unity, but its proof reduces to Theorem 9.5.17, which assumes them for X; the polyfold theorem is proved with the same hypothesis, in the form of Definition 16.1.5. It is not derived from the text. *Witness* Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.theorem_16_4_6_hyp_witness: the polyfold $\mathbb{R}$ of §XVI.1 admits sc-smooth partitions of unity Chapter16/PolyfoldExamples · PolyfoldStructure.z3Polyfold_admitsScPartitionsOfUnity. Without the hypothesis the theorem is gap G.153 (§XVI.28). *Reading.* "Tame" is Chapter 9's, on the representative used; by §XVI.19, Step 4, it holds on every representative.

Where Lean departs from the text. None in the argument: the text's proof is the reduction to Theorem 9.5.17 in a representative, and the formalization is that reduction with each translation step made explicit. The departure is in the statement, which carries the hypothesis of Theorem 9.5.17 that the polyfold statement does not print. Dimension 1 is stated separately because there the boundary of $\hat\theta$ is a weighted finite set of points and the boundary measure of Chapter 9 is a weighted sum of values rather than an integral over a manifold; Theorems 9.5.17 and 9.5.18 have separate forms for it, and the polyfold theorem inherits the split. The four Lean statements together cover every dimension $n \geq 1$ and both integrals.

XVI.21 Definitions 16.5.1, 16.5.2, Remark 16.5.3 and (16.8) (2017: Definitions 16.35, 16.36, Remark 16.5), p. 733: sc⁺-multisections and $n(\lambda)$

Statement. *Definition 16.5.1* (same) Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection: an sc⁺-multisection $\lambda : Y \to \mathbb{Q}^+$ of a strong polyfold bundle is a class of representatives $(\lambda,\Gamma,W,\Lambda)$ Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.MultisectionRep, Λ an sc⁺-multisection functor of a structure of $\bar c$ (Definition 13.1.4) with $\lambda(\Gamma|w|) = \Lambda(w)$; two are related if $\lambda = \lambda'$ and $\Lambda = \bar f^*\Lambda'$ for a generalized strong bundle isomorphism $\bar f$ with $\Gamma' \circ |\bar f| = \Gamma$ Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.MultisectionRep.Rel. *Definition 16.5.2* (restated) Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection.domSupp: the domain support of λ is the closure of the set of z over which some $y \neq 0_z$ has $\lambda(y) > 0$. *Remark 16.5.3* (same, with γ for the printed Γ) Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.remark_16_5_3: for a representative, $\gamma(|\text{dom-supp }\Lambda|) = \text{dom-supp }\lambda$. *(16.8)* (same) Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.normLam Chapter16/NormLamContinuous · StrongPolyfoldBundle.ScPlusMultisection.continuous_normLam: for an auxiliary norm n, $n(\lambda)(z) = \max\{n(y) : p(y) = z, \lambda(y) \neq 0\}$ is a continuous function $Z \to [0,\infty)$.

Background: sc⁺-multisection functors. Over an ep-groupoid, an sc⁺-multisection functor (Definition 13.1.4, Part XIII) is a functor $\Lambda : W \to \mathbb{Q}^+$ which near every object x has a local section structure: an invariant open neighbourhood O of x, finitely many sc⁺-sections $s_1, \dots, s_k$ of P over O and positive rational weights $\sigma_1, \dots, \sigma_k$ with $\sum_i \sigma_i = 1$, such that $\Lambda(w) = \sum_{i : s_i(P(w)) = w} \sigma_i$ for w over O. Thus over every object the values of Λ on the fibre are finitely many positive weights summing to 1, carried by the values of the local sections, and Λ vanishes elsewhere. The domain support (Definition 13.2.2) is the closure of the objects over which Λ charges a non-zero vector, and for an auxiliary norm N the pointwise norm $N(\Lambda)(x)$ (Definition 13.2.3) is the largest $N(w)$ over the charged vectors w of the fibre. A multisection is structurable (Definition 13.3.6) if it admits local section structures that fit together under the morphisms, the condition under which the perturbation theory of Chapters 14 and 15 works. An sc⁺-multisection of a strong polyfold bundle is the function on Y that such a functor induces through Γ.

Proof of Definition 16.5.1. *Step 1, the map $x \mapsto \gamma(|x|)$* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundleStructure.continuous_γπ` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundleStructure.surjective_γπ` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundleStructure.isSaturated_preimage_γπ`: it is continuous, surjective, and preimages of sets of Z are saturated; and $p(\Gamma(|w|)) = \gamma(|P(w)|)$ `Chapter16/PolyfoldMultisections · StrongPolyfoldBundleStructure.p_Γ_π`. These are the translations used throughout §§16.5–16.6. *Step 2, the relation does not depend on $\bar f$* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.pullMult_eq_of_Γ`. By §XVI.11 the isomorphism $\bar f$ need not be unique; but for every $\bar f$ with $\Gamma' \circ |\bar f| = \Gamma$ and every functor Λ' represented by λ, $(\bar f^* \Lambda')(w) = \lambda(\Gamma|w|)$. The pull-back of a multisection functor along a generalized strong bundle isomorphism is read on orbits (Part XIII), Λ' is $\lambda \circ \Gamma' \circ \pi$, and $\Gamma' \circ |\bar f| = \Gamma$. *Step 3* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.MultisectionRep.rel_iff` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.MultisectionRep.rel_of_lam_eq`: so two representatives are related iff their functions agree and their structures are equivalent; and it is an equivalence relation `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.MultisectionRep.setoid`. *Step 4, the check on the $\mathbb{Z}/3$ example* `Chapter16/RepresentativeChecks · StrongPolyfoldBundle.pullMult_z3_independent`: on the strong bundle of §XVI.11, the two generalized isomorphisms $[1_W]$ and $[W \xleftarrow{1} W \xrightarrow{\mathrm{Inv}} W]$ pull every multisection functor back to the same functor, as Step 2 predicts. *Step 5, a multisection is its function* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection.toFun` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection.ext_toFun`. *Step 6, representatives in every structure* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.exists_rep_of_mem`: every structure of $\bar c$ carries a representative of every λ, by pulling back a representative along a realizing isomorphism and Proposition 11.5.3 (Part XI), which keeps sc⁺-multisection functors. *Step 7* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ofFunctor`: an sc⁺-multisection functor in one structure of $\bar c$ defines an sc⁺-multisection. *Witness* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.zero`: the trivial multisection, $\lambda = 1$ on the zero section and 0 elsewhere.

Proof of Definition 16.5.2 and Remark 16.5.3. *Step 1, the printed set is all of Z* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection.domSuppText` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection.domSuppText_eq_univ`. As printed, dom-supp(λ) is the closure of $\{z : \exists y \in p^{-1}(z),\ \lambda(y) > 0\}$. Over every z the weights of λ sum to 1 (Definition 13.1.4, through a representative), so some y has $\lambda(y) > 0$, and the set is Z. With $y \neq 0_z$, as in Definition 13.2.2 (Part XIII), it is the intended set: the domain support of the ep-groupoid notion is defined with $w \neq 0$. *Step 2, the set before the closure* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.nzSet` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.isSaturated_nzSet` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.image_nzSet`: in a representative, the set $\{x : \exists w \in W_x \setminus \{0\},\ \Lambda(w) > 0\}$ is saturated (because Λ is a functor and morphisms act linearly on

fibres, so they preserve non-zero vectors) and its image under $x \mapsto \gamma(|x|)$ is the set before the closure in Definition 16.5.2, using that $\Gamma(|w|) = 0_z$ iff w is a zero (§XVI.16). *Step 3, Remark 16.5.3.* The image of the closure of a saturated set under the open quotient map $x \mapsto \gamma(|x|)$ is the closure of its image; with Step 2 this is $\gamma(|\,\text{dom-supp}\,\Lambda|) = \text{dom-supp}\,\lambda$. The text writes Γ; both sets lie in $|X|$ and Z, so we read γ.

Proof of (16.8), the formula. *Step 1, the definition* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.normLam`: $n(\lambda)(z)$ is the supremum of $n(y)$ over y with $p(y) = z$ and $\lambda(y) \neq 0$, where n is extended by 0 off $Y_{0,1}$ (§XVI.16). *Step 2, in a representative* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.image_normY_eq` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.normLam_eq`: the set of values $\{n(y)\}$ over $\gamma(|x|)$ equals the set $\{N(w) : w \in W_x,\ \Lambda(w) \neq 0\}$, because Γ maps the fibre W_x onto $p^{-1}(\gamma|x|)$ up to the isotropy action, which preserves N and Λ. So $n(\lambda)(\gamma(|x|)) = N(\Lambda)(x)$, the function of Definition 13.2.3 (Part XIII). *Step 3* `Chapter16/NormLamContinuous · StrongPolyfoldBundle.ScPlusMultisection.isGreatest_normLam`: the maximum is attained, since Λ has finitely many non-zero values over each x (finitely many local sections in a local section structure). *Step 4* `Chapter16/NormLamContinuous · StrongPolyfoldBundle.ScPlusMultisection.normLam_nonneg`: $n(\lambda) \geq 0$, as n is.

Proof of (16.8), the continuity. *Step 1, $N(\Lambda)$ is continuous on X* `Chapter16/NormLamContinuous · SBLocalization.IsScPlusMultisection.continuous_pointwiseNorm`. Let Λ be an sc$^+$-multisection functor and N continuous on $W_{0,1}$. Near each x there is a local section structure: sc$^+$-sections $s_1, \dots, s_k$ on an open $O \ni x$ with weights $\sigma_i > 0$ summing to 1, with $\Lambda(w) = \sum_{s_i(y)=w} \sigma_i$. On O, $N(\Lambda)(y) = \max_i N(s_i(y))$ `Chapter16/NormLamContinuous · SBLocalization.IsLocalRepOn.pointwiseNorm_eq`, over a non-empty index set `Chapter16/NormLamContinuous · SBLocalization.IsLocalRepOn.univ_nonempty` (the weights sum to 1); every s_i is continuous into $W_{0,1}$, being sc$^+$, so $N \circ s_i$ is continuous, and a finite maximum of continuous functions is continuous. *Step 2, a quotient map* `Chapter16/NormLamContinuous · StrongPolyfoldBundle.isQuotientMap_γπ`: $x \mapsto \gamma(|x|)$ is a quotient map, π being an open quotient map (Proposition 7.1.8, Part VII) and γ a homeomorphism. *Step 3.* $n(\lambda) \circ \gamma \circ \pi = N(\Lambda)$ by the formula, with N the representative of n (continuous by Definition 16.3.9), so $n(\lambda)$ is continuous by Step 2. The text calls $n(\lambda)$ continuous; this is the proof. Gap G.174 is closed.

Where Lean departs from the text. The text defines sc$^+$-multisections by representatives and their relation with a chosen $\bar{f}$; the formalization proves that the choice of $\bar{f}$ does not matter, which the text does not address, and which is needed because $\bar{f}$ is not unique (§XVI.11). The text asserts that $n(\lambda)$ is continuous; the formalization proves it, through the local section structures of Chapter 13 and a quotient map. Definition 16.5.2 is read with $y \neq 0_z$, and Remark 16.5.3 with γ.

XVI.22 Definitions 16.5.4–16.5.6 (2017: Definitions 16.37–16.39), p. 734: structurable multisections, and multisections over ∂Z

Statement. *Definition 16.5.4* (same) `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection.IsStructurable`: λ is structurable if one representative is (Definition 13.3.6); "and therefore all" `Chapter16/StructurablePullback · StrongPolyfoldBundle.ScPlusMultisection.definition_16_5_4`. *Definition 16.5.5* (restated) `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisection`: sc$^+$-multisections of $Y|\partial Z$, classes of representatives with Λ a multisection functor on $W|\partial X$ (Definition 14.1.3) `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisectionRep`. *Definition 16.5.6* (same) `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisection.IsStructurable`: λ over ∂Z is structurable if one representative is (Definition 14.1.7). The text writes $\lambda : Z \to \mathbb{Q}^+$ in Definition 16.5.4; we read $\lambda : Y \to \mathbb{Q}^+$, the domain of Definition 16.5.1.

Proof of Definition 16.5.4. *Step 1, the pull-back proposition* `Chapter16/PolyfoldMultisections · StructurablePullback`: pull-backs of structurable sc⁺-multisection functors along generalized strong bundle isomorphisms are structurable. *Step 2, from it the class statement* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.ScPlusMultisection.definition_16_5_4_hyp`: if one representative is structurable, every other is its pull-back along a realizing isomorphism, by Step 2 of §XVI.21, and so is structurable. *Step 3, the proposition holds* `Chapter16/StructurablePullback · fnStructurablePullback`: by Theorems 13.4.1 and 13.4.3 for generalized isomorphisms (Part XIII), which pull back structured representatives along the two legs of a diagram. So Definition 16.5.4 holds as printed `Chapter16/StructurablePullback · StrongPolyfoldBundle.ScPlusMultisection.definition_16_5_4`. *Witness* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.zero_isStructurable`: the zero multisection is structurable.

Proof of Definition 16.5.5. *Step 1, the boundary* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.mem_boundary_iff_obj`: $\gamma(|x|) \in \partial Z$ iff $x \in \partial X$ (§XVI.5). *Step 2, the relation* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisectionRep.Rel`: $\lambda = \lambda'$ over ∂Z, and a generalized strong bundle isomorphism $\bar{f}$ with $\Gamma' \circ |\bar{f}| = \Gamma$ has $\Lambda(w) = \Lambda'(w')$ whenever $|\bar{f}|(|w|) = |w'|$ over ∂X. *Restated* because the pull-back of multisection functors over the boundary is read in this orbit form: a pull-back over ∂X along generalized isomorphisms is part of the gap of Proposition 14.1.8 over ∂X (Part XIV). *Step 3* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisectionRep.rel_iff` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisectionRep.rel_of_lam_eq`: as for Definition 16.5.1, two representatives are related iff their functions agree over $p^{-1}(\partial Z)$ and their structures are equivalent. *Step 4, the function* `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisection.toFun` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisection.toFun_mk_of_mem`: λ on $Y|\partial Z$, read as 0 off $p^{-1}(\partial Z)$, is well defined.

Proof of Definition 16.5.6. Structurability over ∂Z is that of one representative, as printed. The domain support over ∂Z `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisection.domSupp` is Definition 16.5.2 read over ∂Z, as Theorem 16.5.7 uses it, and $|\partial\text{-dom-supp}(\Lambda)| \subseteq \partial\text{-dom-supp}(\lambda)$ through $x \mapsto \gamma(|x|)$ `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.boundaryDomSupp_subset`, the image of the closure lying in the closure of the image by continuity. The text adds no "and therefore all" here; the invariance would need the boundary pull-back of Step 2 above.

Where Lean departs from the text. The text's "and therefore all" in Definition 16.5.4 is left unproved; the formalization isolates the proposition it needs, that structurability pulls back along generalized strong bundle isomorphisms, and proves it from Theorems 13.4.1 and 13.4.3. Definition 16.5.5 is restated, since the pull-back of multisection functors over the boundary along generalized isomorphisms is not available as formalized; its orbit form suffices for the relation, by the same argument as for Definition 16.5.1.

XVI.23 Theorem 16.5.7 (2017: Theorem 16.6), p. 735: extension of sc⁺-multisections from the boundary

Statement (with added hypotheses) `Chapter16/PolyfoldBoundaryExtension · theorem_16_5_7_a6`. Let $p : Y \to Z$ be a tame strong polyfold bundle whose models admit sc-smooth partitions of unity on the objects and tame strong bundle charts at every object, n an auxiliary norm, λ an sc⁺-multisection over ∂Z that is structurable with non-empty index sets `Chapter16/PolyfoldBoundaryExtension · BoundaryMultisection.IsStructurableNe`, $\tilde{U}$ an open set containing dom-supp(λ), and $f : Z \to [0, \infty)$ continuous with closed support in $\tilde{U}$ and $n(\lambda) < f$ on dom-supp(λ). Then there is a structurable sc⁺-multisection λ' with (1) $n(\lambda') \le f$, (2) dom-supp$(\lambda') \subseteq \tilde{U}$, and (3) $\lambda' = \lambda$ over ∂Z.

Readings and added hypotheses. (a) *Non-empty index sets* `Chapter16/PolyfoldBoundaryExtension · BoundaryMultisection.IsStructurableNe`: λ has a representative structurable over ∂X whose Λ charges every boundary fibre; this implies Definition 16.5.6 `Chapter16/PolyfoldBoundaryExtension · BoundaryMultisection.IsStructurableNe.isStructurable`. The text's λ is an sc$^+$-multisection over ∂Z, whose local section structures have non-empty index sets (the weights sum to 1 over each boundary fibre), so this is the text's notion, made explicit because Definition 14.1.3 as formalized admits empty index sets. (b) *Tame strong bundle charts* at every object of every model: an added hypothesis, not derived from the text; it is the reading of Theorem 14.1.9 in Part XIV, where the derivation of such charts from tameness is a gap of that Part. (c) *Partitions of unity* on the objects of every model, the form Theorem 14.1.9 uses; for a polyfold this is Definition 16.1.5 (2) in the object form. (d) "Support" is the closed support.

Proof. *Step 1, choose the model.* Take a representative $a = (\lambda, \Gamma, W, \Lambda)$ over ∂X in a structure S of $\bar{c}$, with Λ structurable and charging every boundary fibre. Let $g = \gamma \circ \pi : X \to Z$; it is continuous (§XVI.21).

Step 2, translate the hypotheses to X. The open set $g^{-1}(\tilde{U})$ is open and saturated `Chapter16/PolyfoldMultisections · StrongPolyfoldBundleStructure.isSaturated_preimage_γπ`. $f \circ g$ is continuous, non-negative, invariant under morphisms (since g is), and its closed support lies in $g^{-1}(\tilde{U})$ `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.tsupport_comp_subset_preimage'`, the closed support of a composite with a continuous map lying in the preimage of the closed support. The boundary domain support of Λ maps into that of λ (§XVI.22), hence lies in $g^{-1}(\tilde{U})$. For x in the boundary domain support of Λ, $x \in \partial X$ (it lies in the closure of a set of boundary points, and ∂X is closed), and $N(\Lambda)(x) = n(\lambda)(g(x))$ by (16.8) in the representative (§XVI.21), with the value of λ over the boundary read through the representative: for w over x, $p(\Gamma|w|) = g(x) \in \partial Z$ `Chapter16/PolyfoldMultisections · StrongPolyfoldBundleStructure.p_Γ_π` `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.mem_boundary_iff_obj`, so $\lambda(\Gamma|w|) = \Lambda(w)$ `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.BoundaryMultisection.toFun_mk_of_mem`. So $N(\Lambda) < f \circ g$ on the boundary domain support of Λ.

Step 3, Theorem 14.1.9 in the model. The charged form of Theorem 14.1.9 (Part XIV) applies in S: X is tame (Definition 16.3.5 (1)), $|X|$ paracompact (Definition 16.3.1), partitions of unity and tame strong bundle charts by (b), (c), Λ structurable over ∂X and charging every boundary fibre by (a), N an auxiliary norm by Definition 16.3.9, and the data of Step 2. It gives a structurable sc$^+$-multisection functor Λ' with $N(\Lambda') \le f \circ g$, dom-supp$(\Lambda') \subseteq g^{-1}(\tilde{U})$ and $\Lambda' = \Lambda$ over ∂X.

Step 4, back to Y. Let λ' be the sc$^+$-multisection of Λ' (§XVI.21, Step 7); it is structurable by Definition 16.5.4. (1): every z is $g(x)$ `Chapter16/PolyfoldMultisections · StrongPolyfoldBundleStructure.surjective_γπ`, and $n(\lambda')(g(x)) = N(\Lambda')(x) \le f(g(x))$ by (16.8). (2): by Remark 16.5.3, dom-supp$(\lambda') = g(\text{dom-supp}\,\Lambda') \subseteq \tilde{U}$. (3): every y over ∂Z is $\Gamma(|w|)$ with $P(w) \in \partial X$, and $\lambda'(y) = \Lambda'(w) = \Lambda(w) = \lambda(y)$.

Where Lean departs from the text. The text's proof is "Theorem 14.1.9 in a representative"; the formalization carries the translation of each hypothesis and conclusion explicitly, through (16.8) and Remark 16.5.3.

A remark on a superseded Lean statement. The declaration `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.theorem_16_5_7_hyp` proves the same conclusion with "Theorem 14.1.9 holds in every model of $\bar{c}$" as a hypothesis, where Theorem 14.1.9 is the Lean statement in which multisections over ∂X may have empty index sets (Definition 14.1.3 as formalized admits them). That Lean statement of Theorem 14.1.9 does not hold when $\partial X \neq \emptyset$ (Part XIV), so this declaration is vacuous for polyfolds with boundary, the case the theorem is about; its other hypotheses are jointly satisfiable on every tame bundle `Chapter16/PolyfoldMultisections · StrongPolyfoldBundle.theorem_16_5_7_hyp_witness`, with the zero multisection over ∂Z,

$\tilde{U} = \emptyset$ and $f = 0$. The statement above, with non-empty index sets, is the one that formalizes Theorem 16.5.7.

Witness of the hypotheses. The ep-groupoid hypotheses of the charged Theorem 14.1.9 hold, with boundary and non-zero fibres, on the half-space bundle of Part XIV. No strong polyfold bundle is built on it, so at the level of polyfolds the tame strong bundle charts and the non-empty index sets have no witness of their own; the remaining hypotheses are witnessed as above, and partitions of unity by the polyfold $\mathbb{R}$ (§XVI.27).

XVI.24 The claim before Definition 16.6.1, Definitions 16.6.1–16.6.3 and Theorem 16.6.4 (2017: Definitions 16.40, 16.41, Theorem 16.7), pp. 735–737: sc-Fredholm sections

Statement. *The claim* (pp. 735–736, same) `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.isFredholm_iff`: if one representative of an sc-smooth section is an sc-Fredholm section functor (Definition 12.1.2), every other is; a section is sc-Fredholm if one representative is `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.IsFredholm`. *Definition 16.6.1* (p. 736, same) `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.FredholmSection`: the sc-Fredholm sections. *Definition 16.6.2* (p. 736, same) `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.HasCompactSolutionSet`: f has a compact solution set if $S_f = \{z : f(z) = 0_z\}$ `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.solutionSet` is compact. *Definition 16.6.3* (pp. 736–737, same; new in 2021) `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.IsProper` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.IsProperLtInfty`: (1) f is proper if for every auxiliary norm n there is an open $U \supseteq S_f$ with $\{z \in U : n(f(z)) \le 1\}$ having compact closure; (2) f is proper$< \infty$ if the same holds for every C in place of 1, with U depending on C; (n, U) controls compactness if U works with $C = 1$ `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.ControlsCompactness`. *Theorem 16.6.4* (p. 737, same) `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.theorem_16_6_4`: for an sc-Fredholm section, a compact solution set, proper and proper$< \infty$ are equivalent.

Proof of the claim and Definition 16.6.1. *Step 1.* Two representatives are related by a generalized strong bundle isomorphism pushing one functor to the other (§XVI.16). *Step 2.* Theorem 10.5.4 (Part X): the push-forward of an sc-Fredholm section functor along a generalized strong bundle isomorphism is sc-Fredholm, since the legs are local strong bundle isomorphisms and the sc-Fredholm property is local and invariant under them (Part XII). *Step 3* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.exists_rep_of_mem`: every structure of $\bar{c}$ carries a representative of every sc-smooth section, by pushing a representative along a realizing isomorphism. So the property is that of any representative in any structure.

The dictionary between Z and a representative. For a representative $a = (f, \Gamma, W, F)$ write $g = \gamma \circ \pi : X \to Z$. *Step 1* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.isSection_F`: $P \circ F = \mathrm{id}$. *Step 2* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.Γ_mem_Y01_iff`: $\Gamma(|w|) \in Y_{0,1}$ iff $w \in W_{0,1}$. *Step 3, the solution set* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.solutionSet_eq`: $S_f = g(S_F)$, because $f(g(x)) = \Gamma(|F(x)|)$ and $\Gamma(|w|) = 0_z$ iff w is a zero (§XVI.16). *Step 4, sublevel sets* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScSection.sublevel` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.sublevel_eq`: $\{z \in V : f(z) \in Y_{0,1},\ n(f(z)) \le C\} = g(\{x \in g^{-1}(V) : N(F(x)) \le C\})$ with N

the representative of n; the text's "$n(f(z)) \le C$" is read as $f(z) \in Y_{0,1}$ and $n(f(z)) \le C$, since n is defined on $Y_{0,1}$. *Step 5, topology* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.isOpen_g_image` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.preimage_g_image` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.isCompact_closure_g_image_iff`: g is open, a saturated set is the preimage of its image, and a saturated set has compact closure in X's orbit space iff its image has compact closure in Z (the image of a compact set under the continuous g is compact; conversely, γ is a homeomorphism, so compactness in Z is compactness in $|X|$, which is the meaning of compact closure for saturated sets in Chapter 12). *Step 6, the U-conditions* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.forall_iff_of_saturated` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.forall_iff_of_open` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.solutionSet_subset_iff` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.solutionSet_subset_preimage_iff`: an open $U \supseteq S_f$ in Z corresponds to the saturated open $g^{-1}(U) \supseteq S_F$, and conversely a saturated open $U' \supseteq S_F$ to $g(U')$, with the sublevel conditions corresponding for each C. *Step 7, every auxiliary norm* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.forall_auxNorm_iff`: "for every auxiliary norm n of Y" may be read as "for every auxiliary norm N of W", since auxiliary norms correspond by descent and representation (§XVI.13).

Proof of Definitions 16.6.2, 16.6.3 in a representative. *Definition 16.6.2* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.hasCompactSolutionSet_iff`: S_f is compact iff $|S_F|$ is, by Steps 3 and 5; that is Definition 12.4.1 (1). *Definition 16.6.3 (1)* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.isProper_iff`: by Steps 4–7 it is Definition 12.4.1 (2). *Definition 16.6.3 (2)* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.isProperLtInfty_iff`: Definition 12.4.1 (3). *Controlling compactness* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.SectionRep.controlsCompactness_iff`: (n, U) controls compactness iff $(N, g^{-1}(U))$ does in the sense of Definition 15.3.1 (Part XV).

Proof of Theorem 16.6.4. Take a representative in any structure (Step 3 of the claim). By the translations above, the three conditions are those of Definition 12.4.1 for F, and Theorem 12.4.2 (Part XII) shows that they are equivalent for an sc-Fredholm section functor over an ep-groupoid with paracompact orbit space, which every structure of $\bar{c}$ has.

Where Lean departs from the text. The text proves the claim before Definition 16.6.1 by Theorem 10.5.4, and Theorem 16.6.4 by Theorem 12.4.2 in a representative; the formalization follows both. What it adds is the dictionary between conditions on Z, Y and conditions on a model, which the text leaves implicit: solution sets, sublevel sets, open neighbourhoods of the solution set, compact closures and the quantifier over auxiliary norms. Each translation is a separate lemma, and together they show that every notion of Definitions 16.6.2 and 16.6.3 is, in every representative, the corresponding notion of Definition 12.4.1.

XVI.25 Definition 16.6.5 (2017: Definition 16.42), p. 739: orientations of sc-Fredholm sections

Statement (narrower). *The definition* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.OrientationRep` `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.FredholmSection.IsOrientable`: an orientation of an sc-Fredholm section f is an orientation of a representative (W, F): sc$^+$-sections through every point, a topology on the orientation bundle O_F as in Theorem 12.5.3, and an orientation in the sense of Definition 12.5.4; f is orientable if one exists. *The transport* `Chapter16/OrientationTransport · StrongPolyfoldBundle.`

`OrientationRep.transport_hyp`: an orientation of one representative gives one of every other representative, the text's "an orientation of one representative determines orientations of all". *Narrower* in two ways: the standing hypotheses of the M-polyfold theory (tameness, sc-smooth bump functions, tame sc-Fredholm germs) are taken on the bundles of the diagram along which the orientation is carried, as in Theorem 12.5.7; and that the carried orientation does not depend on the diagram is not formalized. Both are gap G.176, formalized in part (§XVI.28).

Background: orientations of sc-Fredholm section functors. For an sc-Fredholm section functor F of a strong bundle over an ep-groupoid, Chapter 12 attaches to every smooth point x the set of linearizations of F at x, which differ by sc$^+$-operators, and to each linearization its determinant line; Theorem 12.5.3 shows that these lines form a bundle O_F over the smooth points with a topology for which local sc$^+$-sections through a point give continuous local trivializations. An orientation (Definition 12.5.4) is a choice of one of the two orientations of each determinant line that is continuous in this topology and invariant under the morphisms of X, which act on linearizations by conjugation with the local strong bundle isomorphisms of the action. Theorem 12.5.7 shows that a strong bundle equivalence transports orientations, because it identifies linearizations at corresponding points. On a polyfold an orientation is therefore an orientation of one representative together with the promise, made by the text and proved here in part, that the transports to every other representative are consistent.

Proof of the transport along a diagram `Chapter16/OrientationTransport · SBLocalization.SDiagram.orientation_transport_hyp`. *Statement:* for a diagram $D = [W \xleftarrow{L} W'' \xrightarrow{L'} W']$ of strong bundle equivalences with $[D]_*F = F'$ and an orientation o of F in the sense of Definition 12.5.4, for any topology on O_F as in Theorem 12.5.3, there is exactly one invariant orientation o' of F' compatible with o over W'', and it satisfies Definition 12.5.4 for every topology on $O_{F'}$ as in Theorem 12.5.3. *Step 1, pull back along L.* Theorem 12.5.7 (Part XII) carries o to an orientation of L^*F on W'', the linearizations of F and L^*F being identified by the local strong bundle isomorphisms of L; the standing hypotheses on W and W'' are those of Theorem 12.5.7. *Step 2, push forward along L'.* The same theorem in the other direction carries it to F', using $[D]_*F = F'$, that is $L'_*L^*F = F'$ up to the identification of the middle. *Step 3, uniqueness and invariance.* An invariant orientation of F' is determined on orbits, and over the image of L' it is forced by compatibility; since L' is essentially surjective, every orbit meets the image. *Step 4, continuity for every topology* `Chapter16/OrientationTransport · SBLocalization.SDiagram.exists_orientation_of_eq`: Theorem 12.5.3 allows several topologies on O_F, all with the same continuous sections in the sense used by Definition 12.5.4; Part XII identifies the two readings of continuity, and an orientation for every such topology carries over along an equality $F_1 = F_2$.

Proof on classes. *Step 1* `Chapter16/OrientationTransport · StrongPolyfoldBundle.OrientationRep.exists_diagram`: for an orientation of a representative (W, F) and any other representative (W', F') of the same section, a diagram D with $[D]_*F = F'$ exists, by §XVI.16 (related representatives are related by a generalized strong bundle isomorphism pushing one functor to the other) and a representative diagram of that isomorphism. *Step 2* `Chapter16/OrientationTransport · StrongPolyfoldBundle.OrientationRep.transport_hyp`: the transport along D gives an orientation of F'.

What is not formalized. (i) Two diagrams give the same transported orientation; this needs a common refinement and the compatibility of the orientation maps of Theorem 12.5.7 with composition and with natural equivalences, which Part XII proves for the data of diagrams. (ii) The standing hypotheses on the middle bundle W'' of a diagram follow from those on W and W'; this needs the transfer of tameness, bump functions and tame germ data along strong bundle equivalences. On the $\mathbb{Z}/3$ example the two isomorphisms of §XVI.11 are the identity on objects and transport alike; no example was found where

the diagram matters.

Where Lean departs from the text. The text says that an orientation of one representative determines orientations of all, by Theorem 12.5.7, and defines the orientation of f as the resulting class. The formalization proves the first half, the transport along any diagram, and stops short of the second: that the result does not depend on the diagram, which the text does not argue, and which would be needed for the orientation of f to be a well-defined class rather than a choice on one representative. The formal Definition 16.6.5 therefore records the orientation on one representative, which is what Theorem 16.6.6 uses.

XVI.26 Theorem 16.6.6 (2017: Theorem 16.8), p. 739: the invariant of an oriented sc-Fredholm section

Statement (narrower) `Chapter16/PerturbedIntegralIndependence · StrongPolyfoldBundle.theorem_16_6_6_hyp`. The text: for $\partial Z = \emptyset$, f an oriented sc-Fredholm section with compact solution set, n an auxiliary norm and U open with (n, U) controlling compactness, there are structurable sc$^+$-multisections λ controlled by (n, U) in general position; $\lambda \circ f$ is a compact branched suborbifold with an orientation inherited from (f, o), and $\Phi_{(f,o)}([\tau]) = \int_{(\lambda\circ f,o)} \tau$ defines a linear map on cohomology that does not depend on λ. *The statement in Lean* `Chapter16/PerturbedIntegralIndependence · StrongPolyfoldBundle.theorem_16_6_6_statement`, degree-wise in the dimension $m + 1$ of $\lambda \circ f$, with a parameter IsInherited, a predicate on pairs of an orientation of f and an oriented perturbation: under the text's hypotheses, for every orientation o of f, (i) for every admissible oriented perturbation with the inherited orientation, $\int$ and $\oint$ depend only on $[\tau]$, and (ii) for closed τ, any two such perturbations give the same $\int$ and the same $\oint$. *Proved* given sc-smooth partitions of unity on Z and cobordisms between any two such perturbations. *Narrower*: "inherited from (f, o)" is a parameter; the cobordisms are a hypothesis; "general position" is read in one model; index 0 is not covered.

How the pieces fit. Theorem 16.6.6 combines four ingredients, which the formalization keeps separate so that each can be checked against its source. The perturbation λ comes from Theorem 15.3.7 in one model, transported to the polyfold by (16.8) and Remark 16.5.3. The branched suborbifold $\lambda \circ f$ comes from Theorem 15.4.3 in that model, transported by the fact that a branched suborbifold is its function. The integral of a form over it comes from Chapter 9 in that model, transported by Theorems 11.4.1 and 11.4.2, and its dependence only on the cohomology class comes from Stokes' theorem on the polyfold. The independence of λ comes from a cobordism, which Chapter 15 constructs on a cylinder over one model. Of these, the first three are proved here for the polyfold; the fourth and the orientation that it must respect are the open part.

Controlled multisections and admissible perturbations. *Controlled* `Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.ScPlusMultisection.IsControlledBy`: λ is controlled by (n, U) if $n(\lambda) \leq 1$ and dom-supp$(\lambda) \subseteq U$ (the example after Definition 15.3.3). *General position* `Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.ScSection.IsInGeneralPositionWith`: (f, λ) is in general position if, in some model, the representatives (F, Λ) are (Definitions 15.2.1, 15.3.4). *An oriented perturbation of dimension* $m + 1$ `Chapter16/PerturbedIntegralIndependence · StrongPolyfoldBundle.OrientedPerturbation`: a tame compact oriented branched suborbifold whose function is $\lambda \circ f$ for an sc$^+$-multisection λ; it is *admissible* `Chapter16/PerturbedIntegralIndependence · StrongPolyfoldBundle.OrientedPerturbation.IsAdmissible` if λ is controlled by (n, U) and (f, λ) is in general position. The text's $Z_{0,1}$ for the domain of n is read as $Y_{0,1}$.

Proof, $\lambda\circ f$ as a branched suborbifold. *Step 1, the function* Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.perturbedFun Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.IsPerturbedSuborbifold: $\theta = \lambda \circ f : Z \to \mathbb{Q}^+$; a branched suborbifold "is $\lambda \circ f$" if its function is. *Step 2, in a model* Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.toPolyfoldStructure_mem Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.lam_f_eq: the base (X,γ) of a model $S \in \bar{c}$ is a structure of (Z,c), and $\lambda(f(\gamma|x|)) = \Lambda(F(x))$ for representatives F of f and Λ of λ in S. *Step 3, the representative* Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.perturbedRep: $(\Lambda \circ F,(X,\gamma))$, for $\Lambda \circ F$ a branched ep⁺-subgroupoid, which every model admits since every model carries a functor representing λ Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.exists_functor_rep. Its function is $\lambda \circ f$ in every model Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.perturbedRep_toFun Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.perturbedRep_toFun_ofFunctor. *Step 4* Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.isPerturbedSuborbifold_iff Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.isPerturbedSuborbifold_unique: since a branched suborbifold is determined by its function (§XVI.17), $\theta = \lambda \circ f$ iff θ is the class of $(\Lambda \circ F,(X,\gamma))$ in any model, and such θ is unique. *Step 5, existence* (explicit) Chapter16/PerturbedSuborbifold · StrongPolyfoldBundle.exists_isPerturbedSuborbifold_hyp: for $\partial Z = \emptyset$, f sc-Fredholm, (n,U) controlling compactness and λ controlled by (n,U) and in general position in some model, $\lambda \circ f$ is a compact branched suborbifold. In the model, Theorem 15.4.3 (Part XV) makes $\Lambda \circ F$ a compact branched ep⁺-subgroupoid; good position is vacuous without boundary. The tame germ data of the model are inherited as in Part XV.

Proof, the reduction to a model Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.theorem_16_6_6_reduction. For $\partial Z = \emptyset$, f sc-Fredholm with compact solution set, (n,U) controlling compactness and λ controlled by (n,U): in every structure of $\bar{c}$, the representatives F, Λ satisfy the hypotheses of the ep-groupoid statements of §§15.3–15.4. *Step 1.* $\partial X = \emptyset$, since ∂Z is computed in any representative (§XVI.5) Chapter16/PerturbedIntegralIndependence · PolyfoldClass.not_mem_boundary_of_eq_empty. *Step 2.* $|S_F|$ is compact (§XVI.24). *Step 3.* $(N, g^{-1}(U))$ controls compactness (§XVI.24). *Step 4.* Λ is controlled: $N(\Lambda) = n(\lambda) \circ g \le 1$ by (16.8), and dom-supp$(\Lambda) \subseteq g^{-1}(U)$ by Remark 16.5.3.

Proof, the choice of λ Chapter16/PolyfoldFredholmSections · StrongPolyfoldBundle.exists_generalPosition_hyp. From the statement of Theorem 15.3.7 in a representative, with its standing hypotheses (tameness, sc-smooth bump functions, tame germ data), there is a structurable λ controlled by (n,U) with $n(\lambda) < 1$ whose representative is transversal and in general position. *Step 1.* By the reduction, the hypotheses of Theorem 15.3.7 hold in the model. *Step 2.* Theorem 15.3.7 gives Λ. *Step 3.* λ is the multisection of Λ (§XVI.21), structurable (§XVI.22), controlled by (16.8) and Remark 16.5.3. *The hypothesis.* Theorem 15.3.7 in the representative is not an assumption of the text; it is discharged by Part XV's proof of Theorem 15.3.7 for paracompact orbit spaces, which every strong polyfold bundle structure has (Definition 16.3.1). The unconditional form is a one-line corollary, not stated as a separate declaration.

Proof, the integrals on the polyfold. *Step 1, additivity* Chapter16/PerturbedIntegralIndependence · PolyfoldClass.ScForm.toStructure_add Chapter16/PerturbedIntegralIndependence · PolyfoldClass.ScForm.toStructure_zero Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedRep.integral_add Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedRep.integralEff_add Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedSuborbifold.integral_add Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedSuborbifold.integralEff_add: the representative of a sum is the sum of the representatives, and the branched integrals of Chapter 9 are additive in the form. *Step 2, exact forms* Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedRep.integral_d_eq_zero_of_boundary Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedRep.integralEff_d_eq_zero_of_boundary Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedSuborbifold.integral_d_eq_zero Chapter16/

PerturbedIntegralIndependence · PolyfoldClass.OrientedSuborbifold.integralEff_d_eq_zero: for $\partial Z = \emptyset$ with sc-smooth partitions of unity, $\int_{\hat\theta} d\eta = 0$ and $\oint_{\hat\theta} d\eta = 0$ for every tame compact oriented branched suborbifold of dimension $m+1 \geq 1$. By Stokes (§XVI.20), $\int_{\hat\theta} d\eta = \int_{\partial\hat\theta} \eta$, and $\partial\Theta = 0$ because no object lies in ∂X. *Step 3* Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedSuborbifold.integral_add_d Chapter16/PerturbedIntegralIndependence · PolyfoldClass.OrientedSuborbifold.integralEff_add_d: so the integrals depend only on $[\tau]$. *Step 4, compact oriented suborbifolds* Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.integral Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.integralEff: tame compact oriented branched suborbifolds of dimension $m+1$ bundled with their proofs; their integral is, in every model, the integral of Definition 9.5.6 Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.integral_mk_rep (§XVI.19).

Proof, cobordisms. *The notion* Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.HasCobordism Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.HasCobordismEff: P_0 and P_1 are joined by an oriented compact cobordism if there are an ep-groupoid Y with sc-smooth partitions of unity (and, for the effective form, the local unique continuation property), a compact oriented tame branched ep$^+$-subgroupoid $\tilde\Theta$ of Y of dimension $m+2$, and an sc-smooth F from Y into a model of Z, with $\int_{\partial\tilde\Theta} F^*\omega = \int_{P_1}\omega - \int_{P_0}\omega$ for every form ω. This is the shape of the proof of Corollary 15.4.4 (Part XV). *Closed forms* Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.integral_eq_of_hasCobordism Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.integralEff_eq_of_hasCobordismEff: for $d\omega = 0$, $\int_{P_1}\omega - \int_{P_0}\omega = \int_{\partial\tilde\Theta} F^*\omega = \int_{\tilde\Theta} dF^*\omega = \int_{\tilde\Theta} F^* d\omega = 0$, by Theorem 9.5.17 on Y (Theorem 9.5.18 for the effective form) and the commutation of d with pull-back. *Satisfiable* Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.hasCobordism_refl Chapter16/PerturbedIntegralIndependence · PolyfoldClass.CompactOrientedSuborbifold.hasCobordismEff_refl: every P is cobordant to itself, with $Y = X$ and $\tilde\Theta = 0$.

Proof of Theorem 16.6.6. Let o be an orientation of f. (i) For an admissible perturbation with the inherited orientation, $\int_P(\tau + d\eta) = \int_P \tau$ and the same for $\oint$, by the integrals on the polyfold, Step 3. (ii) For two such perturbations P_0, P_1 and closed τ, the cobordism hypothesis gives $\tilde\Theta$, and the closed-forms identity gives $\int_{P_0}\tau = \int_{P_1}\tau$, and likewise for $\oint$. The well-definedness of the integral on the class (§XVI.19) uses no cobordism.

Added hypotheses and parameters. (a) Sc-smooth partitions of unity on Z, the hypothesis of Stokes' theorem (§XVI.20); not derived from the text. Witness: the polyfold $\mathbb{R}$ of §XVI.1 (§XVI.27). (b) The cobordisms between any two admissible perturbations with the inherited orientation: Corollary 15.4.4 on the polyfold, which is gap G.175 in part. *Witness* Chapter16/PerturbedIntegralIndependence · StrongPolyfoldBundle.theorem_16_6_6_hyp_hcob_witness: for the predicate IsInherited that singles out one perturbation P, the cobordism hypotheses hold through the self-cobordism of P. **This witness covers only a degenerate case**: with one perturbation there is nothing to compare, and no strong polyfold bundle with an admissible oriented perturbation of non-empty support is built. (c) "Inherited from (f, o)" is a parameter, any predicate on oriented perturbations; its definition needs the canonical orientation of Theorem 15.4.1 on the polyfold (gap G.159 of Part XV and gap G.175 in part). (d) "Generic" is read as general position in some model; its independence of the model is gap G.187. (e) The degree is the dimension $m+1 \geq 1$ of $\lambda \circ f$; index 0, where the integral is a weighted count of points, is gap G.188, the branched integrals of Chapter 9 being defined in dimension at least 1.

Where Lean departs from the text. The text's proof of Theorem 16.6.6 refers to Chapter 15 in a representative:

Theorem 15.3.7 for the choice of λ, Theorem 15.4.1 for the orientation of $\lambda \circ f$, and Corollary 15.4.4 for the independence of λ. The formalization does the first unconditionally, and isolates the second and third: the orientation as a parameter, the cobordism as a hypothesis. It also separates what does not need Chapter 15 at all: that the integrals are defined on the polyfold and depend only on $[\tau]$ follows from Stokes' theorem alone, because $\partial Z = \emptyset$. The text's statement is in cohomological degree k; the formalization is degree-wise in the dimension $m + 1$ of $\lambda \circ f$, which equals the Fredholm index, and does not cover index 0.

XVI.27 Witnesses and the hypotheses

Hypotheses taken, by section. Each is named, is not derived from the text unless said, and has a witness.

- *§XVI.2, §XVI.7.* The effective forms of the uniqueness after Definition 16.1.2, Remark 16.1.7 and Lemma 16.2.1 take an effective target. Witness: the point ep-groupoid `Chapter16/TangentLemma · PolyfoldStructure.lemma_16_2_1_of_isEffective_hypotheses`. Without it the statements do not hold as we read them; the orbit form of Lemma 16.2.1 needs no added hypothesis.
- *§XVI.4.* An effective middle polyfold for the composition of sc-smooth maps and for Definition 16.1.11. The text claims the composition in general; as we read it, it does not hold without effectiveness. Witness: the one-point polyfold `Chapter16/PolyfoldMaps · EffPolyfold.point`.
- *§XVI.9.* The functor on effective polyfolds takes only effectiveness; (ZHOU), which the effectiveness of the tangent needs, is part of every polyfold structure. The form on classes with an effective middle polyfold whose tangent is effective has that second hypothesis discharged by the theorem that tangents of effective polyfolds are effective, so it holds whenever the composite is defined.
- *§XVI.10.* The pull-back of forms by a composite of classes takes an effective middle polyfold, where the composite is defined; the pull-back by one sc-smooth map takes nothing.
- *§XVI.11.* The effective form of the uniqueness after Definition 16.3.3 takes an effective target base; satisfiable, since trivial ep-groupoids are effective (Chapter 7).
- *§XVI.15.* Theorem 16.3.17 (2): the reflexive local step of Theorem 12.2.13. Witness `Chapter16/PolyfoldAuxNorm · StrongPolyfoldBundle.theorem_16_3_17_two_hyp_witness` on every bundle with reflexive 1-fibres, **degenerate**: the boundary norm is the restriction of a global reflexive norm. The non-degenerate case is Part XII's proof of the local step over tame bases, which Theorem 16.3.17 assumes.
- *§XVI.20.* Sc-smooth partitions of unity, in Theorem 16.4.6 and in the independence of the boundary integrals (§XVI.19). Witness: the polyfold $\mathbb{R}$ `Chapter16/BranchedSuborbifold · PolyfoldClass.OrientedRep.theorem_16_4_6_hyp_witness`.
- *§XVI.23.* Tame strong bundle charts in every model, and sc-smooth partitions of unity on the objects of every model. The partitions of unity are witnessed on the polyfold $\mathbb{R}$; the ep-groupoid hypotheses of the charged Theorem 14.1.9 hold non-degenerately, with boundary and non-zero fibres, on the half-space bundle of Part XIV; at the level of polyfolds, the charts and the non-empty index sets have no witness of their own. The remaining hypotheses (structurable λ over ∂Z, $\tilde{U}$, f) are jointly satisfiable on every tame bundle with the zero multisection, $\tilde{U} = \emptyset$, $f = 0$, which is degenerate.
- *§XVI.25.* The standing hypotheses of the M-polyfold theory on the three bundles of the diagram, as in Theorem 12.5.7; Part XII's witnesses for Theorem 12.5.7 apply.
- *§XVI.26.* Sc-smooth partitions of unity on Z (witness: the polyfold $\mathbb{R}$); the cobordisms (witness **degenerate**: one perturbation, self-cobordism); the predicate "inherited" (a parameter, not a hy-

pothesis on data); the inherited tame germ data in the existence of $\lambda \circ f$.

No hypothesis of this Part quantifies over all charts of a bundle, and none is unsatisfiable: each has a witness above, degenerate where said.

Readings, not hypotheses. Bump functions on the object M-polyfold (decision (2)); the normalization $\widehat{T}_\Theta = 0$ off X_∞ (§XVI.19); $y \neq 0_z$ in Definition 16.5.2 (§XVI.21); γ for Γ in Remark 16.5.3; $\lambda : Y \to \mathbb{Q}^+$ in Definition 16.5.4; $n(f(z)) \leq C$ read with $f(z) \in Y_{0,1}$ in Definition 16.6.3; $Y_{0,1}$ for the printed $Z_{0,1}$ in Theorem 16.6.6; "n reflexive" read in one model in Theorem 16.3.17 (2); the boundary pull-back in orbit form in Definition 16.5.5.

Every definition has a witness.

Polyfolds (on the polyfold $\mathbb{R}$ given by $\mathbb{Z}/3 \times \mathbb{R} \rightrightarrows \mathbb{R}$, §XVI.1). Polyfold structure and polyfold; tame `Chapter16/PolyfoldExamples · PolyfoldStructure.z3Polyfold_isTame`; admits sc-smooth bump functions `Chapter16/PolyfoldExamples · PolyfoldStructure.z3Polyfold_admitsBumpFunctions` and sc-smooth partitions of unity `Chapter16/PolyfoldExamples · PolyfoldStructure.z3Polyfold_admitsScPartitionsOfUnity`; degeneracy index $\equiv 0$ `Chapter16/PolyfoldExamples · PolyfoldStructure.z3Polyfold_degIndex` and empty boundary `Chapter16/PolyfoldExamples · PolyfoldStructure.z3Polyfold_boundary`. The same polyfold is the example of §XVI.2, so the hypotheses of Definition 16.1.1 are satisfiable there in a non-effective way. Its tangent and its raised polyfolds are witnesses of Definition 16.2.3 and of $(Z, c)^i$, τ_Z.

Maps. The identity sc-smooth map on every polyfold; the category PS, with identities; effective polyfolds, the one-point polyfold. *Forms.* $\Omega^k_{sc}(Z, c)$ is a vector space isomorphic to $\Omega^k_{ep,\infty}(X)$ for every structure in c (§XVI.10).

Strong polyfold bundles (on the $\mathbb{Z}/3$ bundle $\mathbb{R} \times \mathbb{R}^k \to \mathbb{R}$, §XVI.11, with non-trivial isotropy). Structure and bundle; tame `Chapter16/PolyfoldBundleExamples · StrongPolyfoldBundle.z3Bundle_isTame`; an invertible morphism of $\mathcal{SPBS}$ `Chapter16/PolyfoldBundleExamples · StrongPolyfoldBundle.z3_id_isInvertible`; reflexive 1-fibres `Chapter16/PolyfoldBundleExamples · StrongPolyfoldBundle.z3Bundle_hasReflexiveFibers`, since $\mathbb{R}^k$ is reflexive; an auxiliary norm `Chapter16/PolyfoldBundleExamples · StrongPolyfoldBundle.z3Bundle_exists_auxNorm` and a reflexive one `Chapter16/PolyfoldBundleExamples · StrongPolyfoldBundle.z3Bundle_exists_reflexiveAuxNorm`; auxiliary norms over the boundary, by restriction `Chapter16/PolyfoldBundleExamples · StrongPolyfoldBundle.IsAuxNorm.isAuxNormBoundary`, and the hypotheses of Theorem 16.3.17 (1) `Chapter16/PolyfoldBundleExamples · StrongPolyfoldBundle.theorem_16_3_17_one_witness`. *Sections.* The zero section on every strong polyfold bundle (§XVI.16), an sc$^+$-section. *Multisections.* The zero multisection, structurable; over ∂Z, the zero multisection of the witness of §XVI.23. *Sc-Fredholm sections and their orientations* are not separately witnessed at the polyfold level; Part XII's examples of sc-Fredholm section functors and orientations give them in any model.

Branched suborbifolds. A class exists as soon as a representative does; $\lambda \circ f$ gives one in every model (§XVI.26). No separate polyfold-level example of a compact tame oriented one is built; the hemisphere of Part IX is the nearest ep-level example.

XVI.28 What is not formalized

- **Gap G.153**: Stokes' theorem on polyfolds without partitions of unity (Theorem 16.4.6). Proved with sc-smooth partitions of unity, as Theorem 9.5.17 assumes (§XVI.20). Missing: Stokes on ep-groupoids without partitions of unity, using a finite cut-off from the compactness of $\operatorname{supp}\Theta$, so

that only finitely many local charts are needed and the partition can be built by hand from bump functions. Estimate: 300–600 lines. A candidate for the notes to the authors: whether the text intends partitions of unity here.

- **Gap G.175 (formalized in part).** Proved: the integrals of Theorem 16.6.6 on the polyfold, their dependence only on $[\tau]$, and their independence of λ given cobordisms (§XVI.26). Missing: (a) the orientation of $\lambda \circ f$ inherited from (f, o), on the polyfold (p. 739, Definition 15.4.2), which is a parameter of Theorem 16.6.6: Theorem 15.4.1 in a model beyond single points (gap G.159 of Part XV); the lift of its orientation to an oriented representative on the model, with independent tangent sums and $\widehat{T} = 0$ off X_∞; its independence of the model, by the transport of o (G.176) and the pull-back of $\widehat{T}$ along generalized isomorphisms; 250–450 lines after G.159. (b) The cobordism between two admissible perturbations, on the polyfold, a hypothesis of Theorem 16.6.6: Corollary 15.4.4 on the cylinder of a model, with the gaps of Part XV; the transfer of its cobordism to the polyfold, the integral side being done by the comparison of integrals in a model; about 80–150 lines; and the effective form, with the local unique continuation property on the cylinder.
- **Gap G.176 (formalized in part)**: orientations of sc-Fredholm sections do not depend on the representative (Definition 16.6.5). Proved: the transport along any diagram with $[D]_* F = F'$, with continuity, and an orientation on every other representative (§XVI.25). Missing: (i) two diagrams give the same transported orientation, through a common refinement and the compatibility of the orientation maps with composition and natural equivalences, which Part XII proves for the data of diagrams; 200–300 lines. (ii) The transfer of tameness, bump functions and tame germ data along strong bundle equivalences, so that the hypotheses on the middle bundle can be dropped; 100–200 lines.
- **Gap G.187**: general position of (f, λ) does not depend on the model; §XVI.26 reads it in one model. Missing: the invariance of general position under generalized strong bundle isomorphisms, the linearizations being transported by the local sc-diffeomorphisms as for Fredholmness in Theorem 10.5.4; 200–350 lines.
- **Gap G.188**: Theorem 16.6.6 in Fredholm index 0, where the integral is a weighted count; the branched integrals of Chapter 9 are defined in dimension at least 1 (§XVI.26); 150–300 lines.
- *Closed gaps of this chapter.* G.146 (metrizability, §XVI.1), G.154 (tameness of branched suborbifolds, §XVI.17), G.155 (Proposition 16.4.3, §XVI.18), G.156 (raised polyfolds and τ_Z, §§XVI.6, XVI.8), G.157 (the tangent of an effective polyfold, §XVI.9), G.166 (reflexivity, mixed convergence and reflexive norms along equivalences, §XVI.14), G.167 (the zero section, §XVI.16), G.174 (continuity of $n(\lambda)$, §XVI.21).
- *Not formalized, small.* The boundary integrals of p. 732 as functions on classes; they follow from the independence among representatives (§XVI.19, Step 6) as the interior integrals do; about 40 lines. Weak face structure under generalized isomorphisms, which Definition 16.3.5 (2) would need in its class form (§XVI.11). The composition of strong polyfold bundle maps on classes, which the text does not define (§XVI.12). The invariance of structurability over ∂Z (§XVI.22), which needs the boundary pull-back of Proposition 14.1.8 (Part XIV).
- *Not formalized, no formal content.* The second sentence of Remark 16.1.7, on continuous maps; Remark 16.3.11, which is prose.
- *Not yet formalized.* Proposition 16.1.12 (the lifts Z_i and their topology), Definition 16.1.15 and Remark 16.1.16 (subpolyfolds), Example 16.1.18, Definition 16.1.21 and Proposition 16.1.22 (faces of a polyfold); Remark 16.2.7.
- *Open question, not a gap.* In the example of §XVI.7, $|T\mathfrak{f}| = |T\mathfrak{g}|$ is proved; whether $T\mathfrak{f} \neq T\mathfrak{g}$ is not decided.

XVI.29 What the formalization taught us

(ZHOU) does not give uniqueness of isomorphisms. A polyfold structure in the 2021 sense adds two conditions to the 2017 definition, paracompactness of $|X|$ and (ZHOU), and the text derives from (ZHOU) that the generalized isomorphism realizing an equivalence of structures is unique. Formalized, (ZHOU) gives (LR), and (LR) is the hypothesis of Theorem 10.3.19. But Theorem 10.3.19 does not hold as we read it (Part X), and its example, $\mathbb{Z}/3$ acting trivially on $\mathbb{R}$, satisfies (ZHOU) and has a paracompact orbit space. It is therefore a polyfold structure, and the two generalized isomorphisms $[1_X]$ and $[X \overset{1}{\leftarrow} X \overset{\mathrm{Inv}}{\longrightarrow} X]$ both realize the identity of $\mathbb{R}$. Five statements of the chapter do not hold as we read them for this reason: the uniqueness after Definition 16.1.2, Remark 16.1.7 with the sentence on pp. 709–710, Lemma 16.2.1, the claim of Definition 16.1.10 and the uniqueness after Definition 16.3.3. All five hold for an effective target or middle structure, where Theorem 10.3.19 holds. The isotropy that acts trivially is exactly what (ZHOU) allows and effectiveness forbids.

Where the uniqueness bites, and where it does not. None of the definitions of §§16.1 and 16.3 uses the uniqueness: an equivalence of structures only asks that some generalized isomorphism exist. The polyfold category is where it bites. Definition 16.1.6 lets the isomorphism (k, Id_W) of the middle structure be any generalized isomorphism over Id_W; when the middle structure has isotropy acting trivially, two equivalent representatives of $\hat{f}$ composed with one representative of $\hat{g}$ give inequivalent composites. Presumably the text intends effective polyfolds, or morphisms with a chosen isomorphism; the formalization builds the category of effective polyfolds, while the category PS of polyfold structures, the sc-smooth maps of all polyfolds, their tangents and the pull-back of forms need no restriction, because they are defined map by map and Definition 16.1.6 carries its isomorphisms as data.

Canonical on orbit spaces is enough for §16.2. The text glues $T(Z,c)$ along "the unique" $\mathfrak{f}$ with $\beta \circ |\mathfrak{f}| = \alpha$, and Lemma 16.2.1 is there to make the gluing maps canonical. What the gluing uses is only $|T\mathfrak{f}|$, and that is unique: (LR) gives, for functors with the same orbit map, local families of morphisms between them (Proposition 10.1.10 (1)), and these give the same tangent orbit maps (Proposition 10.1.10 (2)). So $T(Z,c)$, $T\alpha$, (16.5), Lemma 16.2.2 and Definition 16.2.3 go through as printed, with one structure of c as base point instead of the gluing over all. The same argument, Proposition 11.2.9, makes $h_*\omega$ independent of h, which is the remark before Definition 16.2.5. The raised polyfolds follow the same pattern, through the raise of generalized maps.

The tangent of an effective polyfold needs (ZHOU) too. The tangent functor lives on effective polyfolds, because the tangent of an effective polyfold is effective. The proof uses (ZHOU) as well as effectiveness: effectiveness is a statement at level 0, while the open sets of TX see only level 1, so an isotropy element acting trivially near a tangent vector is first moved to a smooth point, where (ZHOU) turns the triviality of the linearized action into triviality near the point.

Invariance statements are statements about equivalences. The invariance statements of §16.1 are statements about equivalences of ep-groupoids, transported to classes. Bump functions are local; partitions of unity are best read on $|X|$; and the text's "easy exercise" in Proposition 16.1.4 (2) is the descent of sc-smoothness along an equivalence. The metrizability of a polyfold follows from Theorem 7.3.1 and the metrization theorem for locally metrizable paracompact Hausdorff spaces, without the Nagata–Smirnov theorem.

§16.4 is Chapters 9 and 11 on classes, with two implicit points. An orientation $\hat{T}_\Theta$ is read only on X_∞, so a representative fixes it to be 0 elsewhere, without which $1^*\hat{T} = \hat{T}$ fails. And Theorem 16.4.6 reduces to Theorem 9.5.17, which is stated for ep-groupoids with sc-smooth partitions of unity; the polyfold version

needs the same hypothesis, which by Definition 16.1.5 holds for every representative as soon as it holds for one. The tameness of branched ep$^+$-subgroupoids moves along equivalences through the transport charts of Theorem 11.4.1, so the integrals live on classes. Proposition 16.4.3 is the same transport once more: the two legs of a generalized isomorphism restrict to equivalences of the sub-ep-groupoids on the supports, and the transition between the induced structures is, near each point, a composite of local sc-diffeomorphisms. The structures of Proposition 9.1.9, which are existential, need not be chosen, since any two give the same comparison.

Functions on Y and Z determine the class-level objects. §§16.3, 16.5 and 16.6 survive the non-uniqueness because their relations are determined by functions. Two representatives of a section are related as soon as their maps f agree: the condition $\mathfrak{A}_* F = F'$ follows from $\Gamma' \circ |\mathfrak{A}| = \Gamma$, since a functor is determined on orbits. Likewise the pull-back of a multisection functor along any generalized strong bundle isomorphism compatible with Γ is $\lambda \circ \Gamma$, whichever isomorphism is chosen; on the $\mathbb{Z}/3$ example both isomorphisms are checked to pull back every functor alike. A branched suborbifold is determined by its function θ, which makes $\lambda \circ f$ a well-defined branched suborbifold. Several conditions the text lists are consequences: the continuity and surjectivity of p, $p' \circ A = a \circ p$ for morphisms, the base condition of Definition 16.3.3.

Small readings. Read literally, the domain support of Definition 16.5.2 is all of Z, since the weights over each fibre sum to 1, so that some y over every z has $\lambda(y) > 0$; with $y \neq 0_z$, as in Definition 13.2.2, it is the intended set. The continuity of $n(\lambda)$ in (16.8) is local: in a local section structure $N(\Lambda)$ is the maximum of the continuous functions $N \circ s_i$, and it descends to Z through a quotient map.

Reflexivity is a transport too. Reflexivity of the 1-fibres pulls back along a local strong bundle isomorphism by transporting a chart, whose fibre model does not change; the push direction needs the same for the action μ along a morphism, which Chapter 10 provides. Mixed convergence moves along a local strong bundle isomorphism because the isomorphism is linear and bounded on the fibres, so bounded sequences stay bounded and weak limits are preserved; the independence of the model for the reflexive notions is again a transport.

§16.6 is a transport, and what remains is ep-level. Once the definitions are on classes, every notion of §16.6 equals the ep-groupoid notion in every representative, and Theorem 16.6.4 is Theorem 12.4.2 there. Theorem 16.5.7 follows from Theorem 14.1.9 in one model, provided the multisections over ∂X have non-empty index sets, which the text's notion has: a Lean form of Theorem 14.1.9 without that condition fails with boundary, and a polyfold theorem built on it would be vacuous exactly in the case it is about. For Theorem 16.6.6 the integrals live on the polyfold and depend only on the class of the form by Stokes alone; what the independence of λ needs is the canonical orientation and a cobordism between two perturbations, both ep-level statements of Chapter 15. Orientations of sc-Fredholm sections follow the same pattern: Theorem 12.5.7 carries one along any diagram, and what is left is that two diagrams carry it alike, for which Part XII's independence of the representative is the tool.
